- Cardiac: signs of congestive heart failure and/or myocardial infarction S3 gallop; pericarditis (friction rub is rare)
- Genitourinary: testicular/epididymal tenderness (can mimic testicular torsion)
- Musculoskeletal: arthritis (usually large joint in lower extremities)

## *DIFFERENTIAL DIAGNOSIS*

- Other forms of vasculitis (ANCA-associated, such as GPA, Churg-Strauss syndrome, and MPA; Henoch-Schönlein purpura, drug-induced vasculitis, cryoglobulinemia, Goodpasture syndrome)
- Buerger disease
- Systemic lupus erythematosus (SLE)
- Embolic disease (atrial myxoma, cholesterol emboli)
- Thrombotic disease (antiphospholipid antibody syndrome)
- Dissecting aneurysm
- Ehlers-Danlos syndrome
- Multiple sclerosis, systemic amyloidosis
- Infection (subacute endocarditis, HIV infection, trichinosis, rickettsial diseases)

## *DIAGNOSTIC TESTS & INTERPRETATION*

- No specific laboratory abnormalities. Confirm diagnosis with biopsy if possible (4)[C].
- Angiography (conventional, CT angiography, or MR angiography) may reveal microaneurysms and/or beading of bifurcating blood vessels.
- Avoid contrast in renal disease.
- Nonspecific laboratory abnormalities:
  - Elevated ESR and CRP
  - Mild proteinuria, elevated creatinine
  - Hepatitis B surface antigen positive in 10-50%
  - Hepatitis C antibody/hepatitis C virus RNA
  - ANCA, antiproteinase 3 (PR3), and anti-MPO are negative. Positive ANCA argues against PAN.
  - Rheumatoid factor may be positive.
  - Anemia of chronic disease (3,4)

## *Initial Tests (lab, imaging)*

Lab tests performed to look for evidence of systemic disease and rule out other causes (3,4):

- CBC, ESR, CRP (elevated) (4)[C]
- Chemistries: elevated creatinine/BUN (4)[C]
- Hepatitis B serology: often positive; hepatitis C less commonly positive
- LFTs: abnormal if involving the liver/biliary tract
- Urinalysis: proteinuria/hematuria, generally no cellular casts or active urinary sediment (4)[C]
- ANA, cryoglobulins (4)[C]
- ANCA, anti-MPO, and anti-PR3 (4)[A]
- Complement levels (C3, C4)
- Angiographic demonstration of aneurysmal changes/beading of small and medium-sized arteries

## *Diagnostic Procedures/Other*

- Electromyography and nerve conduction studies in patients with suspected mononeuritis multiplex. If abnormal, consider sural nerve biopsy.
- Arterial/tissue biopsy
- Skin biopsy from edges of ulcers; include deep dermis and subcutaneous (SC) fat to assess small muscular artery involvement (excisional *not* punch biopsy) (3,4)

## *Test Interpretation*

- Necrotizing inflammation with fibrinoid necrosis of small and medium-sized muscular arteries; segmental, often at bifurcations and branchings. Venules not involved in classic PAN.
- Capillaritis/other lung parenchymal involvement by vasculitis *strongly suggests* another process (microscopic PAN, granulomatosis with polyangiitis [GPA; formerly known as Wegener granulomatosis], Churg-Strauss syndrome, or antiglomerular basement membrane disease).
- Acute lesions with infiltration of polymorphonuclear cells through vessel walls into perivascular area; necrosis, thrombosis, infarction of involved tissue
- Aneurysmal dilatations, including aortic dissection
- Peripheral nerves: 50-70% (vasa nervorum with necrotizing vasculitis)
- GI vessels: 50% (at autopsy) with bowel necrosis; gallbladder and appendix vasculature: 10%

- Muscle vessels: 50%

- Testicular vessels involved in symptomatic males
- *The key differences from other necrotizing vasculitides are lack of granuloma formation and sparing of veins and pulmonary arteries (2,3).*

## TREATMENT

### GENERAL MEASURES

Aggressively treat HTN to prevent associated complications (stroke, myocardial infarction, heart failure)

### MEDICATION

#### First Line

- Severe (life-threatening) disease: corticosteroids (CS) (high-dose prednisone, methylprednisolone, or parenteral Solu-Medrol) (4,10)[A]
  - Only 50% of patients achieve and maintain remission with CS. Other patients require additional immunosuppressive therapy.
  - Cyclophosphamide (CTX) in combination with CS: Improves survival and spares use of chronic steroids in moderate/severe PAN (4,10)[A].
    - CTX has risk of infertility and malignancy.
  - Plasma exchange for refractory and renal disease (4,7)[A]
  - Rituximab use for refractory disease suggested by its efficacy in ANCA + vasculitis (4,12,13) [C].
- Less severe disease: CS alone ± other immunosuppressive agents (azathioprine, (4)[A] methotrexate, mycophenolate mofetil (4,10,14)[B])
- HBV-associated PAN: antiviral agents, short-term CS, plasma exchange (7,10)[C]

#### Second Line

- Tumor necrosis factor inhibitors anecdotally reported to be of use in PAN (15)
- PAN disease activity correlates with serum IL-6 levels; tocilizumab, an inhibitor of IL-6 approved for use in rheumatoid arthritis; no evidence-based data for PAN (16).

## ADDITIONAL THERAPIES

- For patients receiving IV CTX, concurrent administration of mercaptoethane sulfonate reduces bladder exposure to carcinogenic metabolites (4)[C].
- Prophylactically treat patients on CTX for *Pneumocystis jiroveci* (*carinii*) pneumonia with trimethoprim sulfamethoxazole (use dapsone or atovaquone in intolerant/allergic patients) (4).

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

Depends on extent and involvement of specific organs

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

### *Patient Monitoring*

- CBC, urinalysis, renal and hepatic function tests
- Acute-phase reactants (e.g., ESR, CRP) may help monitor disease activity.
- Be alert for the following:
  - Treatment specific side effects of CS and immunosuppressant medications
  - Delayed appearance of neoplasms after treatment, especially bladder malignancy in patients treated with CTX. (Check annual U/A, urinary cytology with urologic evaluation if microscopic hematuria.) (4)[C]
  - Steroid-induced osteoporosis

## DIET

Low salt (HTN)

## PATIENT EDUCATION

- Patient education materials are available from the Arthritis Foundation, 1314 Spring St, NW, Atlanta, GA 30309; 800-283-7800
- ACR website: [www.rheumatology.org](http://www.rheumatology.org)

## PROGNOSIS

- Expected course of untreated PAN is poor, with an estimated 5-year survival of 13% (17).
- Steroid and cytotoxic treatment increase 5-year survival rate to 75-80% (3,17).
- Survival is greater for hepatitis B-related PAN as a result of the introduction of antiviral treatments (7).
- Patients presenting with proteinuria, renal insufficiency, GI tract involvement, cardiomyopathy, or CNS involvement have a worse prognosis.

## COMPLICATIONS

- End-organ damage from ischemia
- Complications from immunosuppressive agents

## Codes

**&NA;**

### ICD10

- M30.0 Polyarteritis nodosa
- M30.1 Polyarteritis with lung involvement [Churg-Strauss]
- M30.8 Other conditions related to polyarteritis nodosa

## Clinical Pearls

**&NA;**

- PAN is a necrotizing vasculitis of small- to medium-sized muscular arteries with lack of granuloma formation that spares veins and pulmonary arteries.
- Clinical features of PAN depend on target organ involvement.
- Skin biopsies at ulcer edges (include deep dermis and SC fat) improve diagnostic yield.
- Check hepatitis B and C serologies.
- ANCA is negative in classic PAN.
- Treatment involves immunosuppression; choice of agent depends on extent and severity of disease.

# Polycystic Kidney Disease

Maricarmen Malagon-Rogers, MD

## BASICS

### DESCRIPTION

- A group of monogenic disorders that results in renal cyst development
- The most frequent are two genetically distinct conditions: autosomal dominant polycystic kidney disease (ADPKD) and autosomal recessive polycystic kidney disease (ARPKD).
- ADPKD is one of the most common human genetic disorders.

### EPIDEMIOLOGY

- ADPKD is generally late onset.
  - Mean age of end-stage kidney disease (ESKD) 57 to 69 years
  - More progressive disease in men than in women
  - Up to 90% of adults have cysts in the liver.
- ARPKD usually present in infants.
  - A minority in older children and young adults may manifest as liver disease.
  - Nonobstructive intrahepatic bile dilatation is sometimes seen.
  - Found on all continents and in all races

### Incidence

- Mean age of ESKD: *PKD1 mutation*, 54.3 years versus *PKD2 mutation*, 74 years
- ARPKD affects 1/20,000 live births; carrier level is 1/70.
- ADPKD affects 1/400 to 1,000 live births.

### Prevalence

As ESKD, ADPKD: 8.7/1 million in the United States; 7/1 million in Europe

# ETIOLOGY AND PATHOPHYSIOLOGY

- ADPKD
  - *PKD1* and *PKD2* mutations disrupt the function of polycystins on the primary cilium, forming fluid-filled cysts that progressively increase in size, leading to gross enlargement of the kidney, and distortion of the renal architecture.
  - Glomerular hyperfiltration compensates for the progressive loss of healthy glomeruli, and therefore, by the time GFR decline becomes detectable, as much as ½ of the original functional glomeruli are irreversibly lost.
  - The majority of patients with ADPKD ultimately progress to ESKD (1).
- ARPKD
  - *PKHD1* product fibrocystin is also located in cilia.
- ADPKD: Cysts arise from only 5% of nephrons:
  - Autosomal dominant pattern of inheritance but a molecularly recessive disease with the 2-hit hypothesis
  - Requires genetic and environmental factors
- ARPKD: Mutations are scattered throughout the gene with genotype-phenotype correlation.

## Genetics

- ADPKD
  - Autosomal dominant inheritance
  - 50% of children of an affected adult are affected.
  - 100% penetrance; genetic imprinting and genetic anticipation are seen as well.
  - Two genes isolated
    - *PKD1* on chromosome 16p13.3 (85% of patients) encodes polycystin 1
    - *PKD2* on chromosome 4q21 (15% of patients) encodes polycystin 2
- ARPKD
  - Autosomal recessive inheritance
  - Siblings have a 1:4 chance of being affected; gene *PKHD1* on chromosome 6p21.1-p12 encodes fibrocystin.

## RISK FACTORS

- Large inter- and intrafamilial variability
- A more rapidly progressive clinical course is predicted by onset of ESKD at <55 years, development of stage 3 CKD at <40 years old, onset of HTN at <18 years, total kidney volume greater than the expected for a given age, or presence of multiple complications (gross hematuria, microalbuminuria) (1).

## GENERAL PREVENTION

Genetic counseling

## COMMONLY ASSOCIATED CONDITIONS

- ADPKD
  - Cysts in other organs
    - Polycystic liver disease in 58% of young age group to 94% of 45-year-olds
    - Pancreatic cysts: 5%
    - Seminal cysts: 40%
    - Arachnoid cysts: 8%
  - Vascular manifestations
    - Intracerebral aneurysms in 6% of patients without family history and in 16% with family history
    - Aortic dissections
  - Cardiac manifestations: mitral valve prolapse: 25%
  - Diverticular disease
- ARPKD: liver involvement: affected in inverse proportion to renal disease; congenital hepatic fibrosis with portal HTN

## DIAGNOSIS

### HISTORY

- ADPKD
  - Positive family history (15% are de novo mutations)
  - Flank pain: 60%

- Hematuria
- UTI
- HTN: 50% aged 20 to 34 years; 100% with ESKD
- Renal failure
- Presymptomatic screening of ADPKD is not currently recommended for at-risk children (2).
  - Blood pressure should be routinely measured in these patients.
- ARPKD
  - 30% of affected neonates die:
    - Enlarged echogenic kidneys and oligohydramnios are diagnosed in utero.
    - Later in childhood: HTN
  - Adolescents and adults present with complications of portal HTN: esophageal varices
  - Hypersplenism

## *PHYSICAL EXAM*

- HTN
- Flank masses

## *DIFFERENTIAL DIAGNOSIS*

- ADPKD and ARPKD
- Tuberous sclerosis: prevalence 1/6,000
- Von Hippel-Lindau syndrome: prevalence 1/36,000
- Nephronophthisis: accounts for 10-20% of cases of renal failure in children; medullary cystic kidney disease
- Renal cystic dysplasias: multicystic dysplastic kidneys: grossly deformed kidneys; most common type of bilateral cystic diseases in newborns (prevalence: 1/4,000)
- Simple cysts: most common cystic abnormality
  - Localized or unilateral renal cystic disease
  - Medullary sponge kidney
  - Acquired renal cystic disease

- Renal cystic neoplasms: benign multilocular cyst (cystic nephroma)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Electrolytes, BUN/creatinine, urine analysis plus urinary citrate

### ***Initial Tests (lab, imaging)***

- ADPKD
  - Renal dysfunction
    - Impaired renal concentration (3), hypocitraturia aciduria
    - Hyperfiltration
    - Elevated creatinine
  - Urinalysis: hematuria and mild proteinuria
- ARPKD
  - Electrolyte abnormalities and renal insufficiency
  - Anemia, thrombocytopenia, leukopenia
- ADPKD
  - US: It is the easiest diagnostic method. However, it is suboptimal for disease exclusion at age <40 years (2)
    - Renal enlargement is universal.
    - In at-risk patients: By age 30 years, two renal cysts (bilateral or unilateral) are 100% diagnostic. In children, it sometimes appears similar to ARPKD; may be diagnosed in utero.
    - Presence of hepatic cysts in young adults is pathognomonic for ADPKD.
    - In the absence of family history, bilateral renal enlargement and cysts make the diagnosis.
  - CT scan/MRI ideally should be part of the initial evaluation (2).
    - Kidney volume assessed by CT or MRI is a main predictor of progression.
    - Helpful in identifying cysts in other organs
    - In subjects <40 years, fewer than five cysts by MRI excludes the diagnosis (2).
- ARPKD

- US: Kidneys are enlarged, homogeneously hyperechogenic (cortex and medulla).
- CT scan is more sensitive if diagnosis is in doubt.
- Presence of hepatic fibrosis helps the diagnosis.

### *Follow-Up Tests & Special Considerations*

- Diagnosis and prevention of secondary problems because of renal and liver abnormalities
- Follow-up of combined renal volume to assess disease severity
- Beyond age 2 years, renal size decreases in ARPKD but continues to grow in ADPKD at an average rate of 5.27% per year. Total kidney volume identifies patients with progressive disease (2).

---

P.821

### *Diagnostic Procedures/Other*

- Genetic testing is available for *PKD1* and *PKD2* in ADPKD when imaging results are equivocal and for potential living related donors (4).
- For *PKHD1* in ARPKD, a prenatal diagnosis is feasible in about 72% of patients.

### *Test Interpretation*

- ADPKD
  - Kidneys are diffusely cystic and, although enlarged, retain their general shape.
  - Cysts range from a few millimeters to several centimeters and are distributed evenly throughout the cortex and medulla.
  - They arise in all segments of the nephron, although they arise initially from the collecting ducts.
  - One kidney may be larger than the other.
- ARPKD
  - Disease is a spectrum, ranging from severe renal disease with mild liver damage to mild renal disease with severe liver damage.
  - Renal enlargement is due to fusiform dilatation of the collecting ducts in the cortex and medulla in the newborn period.
  - Liver lesion is diffuse but limited to fibrotic portal areas.

## TREATMENT

### GENERAL MEASURES

- HTN: moderate sodium restriction, weight control, and regular exercise
- Medications: ACE inhibitors; angiotensin receptor blockers (ARBs)
- Pain: narcotics and other analgesics; bed rest; limit NSAIDs (they worsen renal function)
- Urolithiasis: treated with alkalinization of urine and hydration therapy; surgery as needed
- UTIs/Infections of cysts: lipid-soluble antibiotics more effective (e.g., trimethoprim-sulfamethoxazole and chloramphenicol); fluoroquinolones also useful
- Dialysis for ESKD patients
- Hematuria: Reduce physical activity.

### MEDICATION

- No specific drug therapy is yet available for PKD, although several studies are being conducted for specific treatments (2,5).
- HTN: should be very well controlled to prevent complications. ACE inhibitors are preferred if no contraindications are present.
- The use of antihypertensive medications has been found to decrease mortality (6).
- Hyperlipidemia: statins preferred

### ISSUES FOR REFERRAL

- Nephrologist primary management
- Urologic consultation for management of symptomatic/infected cysts
- Genetic counseling is critical.

### SURGERY/OTHER PROCEDURES

- Indications for surgical intervention
  - Uncontrollable HTN
  - Severe back and loin pain, abdominal fullness
  - Renal deterioration due to enlarging cysts
  - Hematuria/hemorrhage or recurrent UTI

- Open and laparoscopic cyst unroofing: may decrease pain and narcotics requirements; has not been proven to prevent renal failure or to prolong current renal function
- Percutaneous cyst aspiration ± injection of sclerosing agent; not usually performed secondary to recurrent fluid accumulation
- Renal transplant for ESKD

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

Severe pain, gross hematuria with clots

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

None in early stages of the disease; avoid vigorous activity if disease advances. Recurrent gross hematuria is secondary to trauma, associated with faster decline of renal function.

### ***Patient Monitoring***

- Monitor BP and renal function. Encourage hydration. Treat UTI and stone disease aggressively.
- Avoid nephrotoxic drugs.
- Creatinine and BP monitoring at least twice a year; more often as needed
- Screening for intracranial aneurysms (7)

### ***DIET***

- Low-protein diet may retard renal insufficiency.
- Limit caffeine because this might increase cyst growth.
- High water intake to decrease ADH >3 liters a day (5)

### ***PROGNOSIS***

- Renal failure in 2% by age 40 years; 23% by age 50 years; 48% by age 73 years
- ADPKD accounts for 10-15% of dialysis patients.
- No increased incidence of renal cell cancer

## COMPLICATIONS

- Cyst rupture, infection, or hemorrhage
- Progression to renal failure
- Renal calculi

## See Also

**&NA;**

Chronic Kidney Disease

## Codes

**&NA;**

### ICD10

- Q61.3 Polycystic kidney, unspecified
- Q61.19 Other polycystic kidney, infantile type
- Q61.2 Polycystic kidney, adult type

## Clinical Pearls

**&NA;**

- Most PKD patients eventually develop ESKD. No specific treatment has been proven to prevent ESKD, but hydration and control of BP are reasonable goals and should be started soon.
- Patients may benefit from a nephrology consultation after the initial diagnosis to counsel regarding disease progression prevention. Then, they can be followed by primary care if the disease was an incidental finding or no significant kidney dysfunction is present.

# Polycystic Ovarian Syndrome (PCOS)

Maria De La Luz Nieto, MD

## BASICS

### DESCRIPTION

- Polycystic ovarian syndrome (PCOS) is a common endocrine disorder with heterogeneous manifestations that affects up to 7% of the U.S. population.
- Hyperandrogenism leading to anovulation, typically presenting as amenorrhea or oligomenorrhea
- Diagnosis is based on clinical assessment and ultrasound findings.
- Diagnostic clinical characteristics include menstrual dysfunction, infertility, hirsutism, acne, obesity, and metabolic syndrome. The ovaries are often polycystic on imaging.
- The etiology of PCOS is unknown but can be modified by lifestyle factors.
- System(s) affected: reproductive, endocrine/metabolic, skin/exocrine
- Synonym(s): Stein-Leventhal syndrome; polycystic ovary disease

### ALERT

- Condition may begin at puberty.
- Pregnancy does not resolve the syndrome.
- Predisposes to and is associated with obesity, hypertension, diabetes, metabolic syndrome, hyperlipidemia, infertility, insulin-resistance syndrome

### EPIDEMIOLOGY

#### Prevalence

- Incidence and prevalence are still highly debated due to a wide spectrum of diagnostic features: The National Institutes of Health (NIH) criteria require chronic anovulation in addition to clinical or biochemical signs of hyperandrogenism. The prevalence based on NIH criteria is 6.5-8%.
- Predominant age: reproductive age
- Predominant sex: females only

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- PCOS is a multifactorial functional disorder of unclear etiology.
- Recent evidence points to a primary role for insulin resistance with hyperinsulinemia.
- Androgenism: Ovaries are the main source of excess androgens. Polycystic ovaries have thickened thecal layers, which secrete excess androgens in response to luteinizing hormone (LH). LH receptors are overexpressed in thecal and granulosa cells of polycystic ovaries.
- Ovarian follicles: Abnormal androgen signaling may account for abnormal folliculogenesis causing polycystic ovaries. The mechanism that determines abnormal number of follicles is unknown but may be due to abnormal androgen signaling on the ovarian stroma.
- Insulin resistance: Women with PCOS have insulin resistance similar to that in type 2 diabetes. Elevated levels of insulin decrease sex hormone-binding protein (SHBG), increasing bioavailability of testosterone. Insulin may also act directly on adrenal, ovary, and hypothalamus to regulate androgen and gonadotropin release. Insulin resistance causes elevated insulin levels.
- Insulin resistance may cause the frequently associated metabolic syndrome and frank diabetes mellitus.

### **Genetics**

Ultimate expression is likely a combination of polygenic and environmental factors.

## **RISK FACTORS**

See "Commonly Associated Conditions"; cause and effect are difficult to extricate in this disorder.

## **GENERAL PREVENTION**

None known; focus on early diagnosis and treatment to prevent long-term complications.

## **COMMONLY ASSOCIATED CONDITIONS**

- Infertility
- Obesity
- Obstructive sleep apnea
- Hypertension
- Diabetes mellitus

- Endometrial hyperplasia/carcinoma
- Fatty liver disease
- Mood disturbances and depression

## DIAGNOSIS

### HISTORY

- A comprehensive history, including a family history of diabetes and premature onset of cardiovascular disease, is important in the differential diagnosis.
- Focus on the onset and duration of the various signs of androgen excess, menstrual history, and concomitant medications, including the use of exogenous androgens (1).

### PHYSICAL EXAM

- Vital signs: body mass index (BMI), high BP
- General appearance: central obesity, deepened voice, hirsutism, acne
- Skin: hair pattern and growth, acne, seborrhea, acanthosis nigricans
- Genitalia: clitoromegaly and ovarian enlargement

### ALERT

Look specifically for signs of virilization, such as hair pattern, deepened voice, and clitoromegaly.

### DIFFERENTIAL DIAGNOSIS

- Cushing syndrome
- HAIR-AN syndrome
- Testosterone-producing ovarian or adrenal tumor
- Prolactin-producing pituitary adenoma
- Hyperthecosis
- Adult-onset adrenal hyperplasia
- Partial congenital adrenal hyperplasia (21-hydroxylase deficiency)
- 11 $\beta$ -hydroxylase deficiency
- 17 $\beta$ -hydroxysteroid dehydrogenase deficiency

- Acromegaly
- Drug-induced hirsutism, oligo-ovulation (e.g., danazol, steroids, valproic acid)
- Thyroid disease

## *DIAGNOSTIC TESTS & INTERPRETATION*

- The value of measurement of circulating androgens to document PCOS is uncertain but should include measuring free testosterone concentration directly by equilibrium dialysis.
- Most common diagnostic criteria used is Rotterdam criteria (need 2 of 3):
  - Oligo- or anovulation
  - Clinical and/or biochemical signs of hyperandrogenism
  - Transvaginal ultrasonographic polycystic ovaries and exclusion of other etiologies; therefore, consider exclusion of Cushing disease, congenital adrenal hyperplasia, and androgen-secreting tumors.
- More recent criteria also focus on similar criteria while acknowledging that there may be forms of PCOS without overt evidence of hyperandrogenism (2,3)[C].

### *Initial Tests (lab, imaging)*

- Screening workup should include human chorionic gonadotropin (hCG), TSH, prolactin, FSH (exclude premature ovarian failure), DHEAS, 17-OH progesterone, and testosterone level.
- LH determination may be ordered but is not usually necessary:
  - Hirsute women should have a testosterone or free testosterone determination and a DHEAS determination.
  - Consider 17-OH progesterone if congenital adrenal hyperplasia is a possibility.
- LH/FSH level  $\geq 2.5$  to 3/L in  $\pm 50\%$  of women with PCOS, but LH testing is not generally necessary.
- Testosterone increased but  $< 200$  ng/dL (6.94 nmol/L).
- Typical findings in PCOS include mild elevation in DHEAS but  $< 800$   $\mu$ g/dL (20.8  $\mu$ mol/L), mild increase in 17-OH progesterone level, increased estrogen level, and decreased SHBG.
- Drugs that may alter lab results:
  - Oral contraceptives (OCs)

- Steroids
- Antidepressants
- Transvaginal ultrasound findings: one or both ovaries with <sup>3</sup>12 follicles measuring 2 to 9 mm or increased ovarian volume to 10 cm<sup>3</sup>

### *Follow-Up Tests & Special Considerations*

- Consider fasting serum glucose, insulin level, and plasminogen activator inhibitor-1 determinations to establish presence of insulin resistance and glucose intolerance, especially if diagnosis is in doubt.
- Overnight dexamethasone suppression test (Decadron 1 mg PO at 11:00 PM and fasting serum cortisol at 8:00 AM the next morning) to rule out Cushing syndrome in the appropriate setting
- Endometrial biopsy to rule out hyperplasia and/or carcinoma, if indicated
- If the syndrome is diagnosed, determination of fasting glucose and fasting lipid levels should be performed and formal glucose tolerance test is considered.

### *Test Interpretation*

- Ovary usually enlarged with a smooth white glistening capsule
- Ovarian cortex lined with follicles in all stages of development, but most atretic
- Thecal cell proliferation with an increase in the stromal compartment

## **TREATMENT**

### *GENERAL MEASURES*

- No ideal treatment exists.
- Therapy must be individualized according to the needs and desires of each patient.

### *MEDICATION*

Drug costs related to this condition are high.

### *First Line*

- The goal of treatment in PCOS depends on symptoms and patient's goals for fertility.
- Treatment can be divided into five main categories: Lifestyle changes including appropriate

nutrition and exercise to decrease body weight can restore ovulation and increase insulin sensitivity (4)[A],(5)[C].

- Menstrual irregularity when pregnancy not desired:
  - Low-dose OCs (30 to 35  $\mu$ g); newer formulations containing progestins with lower androgenicity (e.g., norethindrone, desogestrel, norgestimate, drospirenone) may be particularly beneficial, but all OCs increase SHBG and decrease excess androgen and estrogen. If unable to tolerate OCs, then intermittent medroxyprogesterone (Provera) 10 mg PO for 10 days given every 1 to 2 months.
  - Metformin may help to correct metabolic abnormalities in women who are shown to be insulin resistant. Initial dose is 500 mg daily for 1 week, increasing by 500 mg/week to a total of 1,500 to 2,000 mg/day divided BID; take with food.
    - Overall, data support the usefulness of metformin on both cardiometabolic risk and reproduction assistance in PCOS women.
    - Thiazolidinediones may increase likelihood of ovulation and treat insulin resistance.
- If pregnancy is desired (6)[B]:
  - Ovulation induction with clomiphene (Clomid, Serophene) and/or exogenous gonadotropins. Birth rate with Clomid is 22.5%, 7.2% with metformin, and 26.8% in women who use both medications.
  - Metformin: 500 to 2,000 mg PO divided BID has been shown to improve hyperandrogenism and restore ovulation. Many times the drug is continued throughout the 1st trimester or the entire pregnancy if there is a history of spontaneous abortion or glucose intolerance. It does improve clinical pregnancy rates but does not improve live birth rates alone or in combination with clomiphene when used for ovulation induction.
  - Has been demonstrated that metformin reduces the incidence of gestational diabetes

## *Second Line*

- Spironolactone for androgen excess hirsutism not addressed by OC therapy
- Cosmetic issues due to hyperandrogenism: Acne may respond best with OCs with low doses of cyproterone or drospirenone.
- Eflornithine hydrochloride 13.9% cream to inhibit hair growth

## **ADDITIONAL THERAPIES**

Weight loss in overweight women results in biochemical and symptomatic improvement in most.

## *ISSUES FOR REFERRAL*

- To reproductive endocrinologist for all women who cannot achieve pregnancy with Clomid
- High-risk pregnancies
- To endocrinologist if Cushing syndrome, congenital adrenal hyperplasia, or adrenal or ovarian tumors are found during the workup

## *SURGERY/OTHER PROCEDURES*

- Ovarian wedge resection and laparoscopic laser drilling are controversial and rarely used today.
- Mechanical means of hair removal, including electrolysis, waxing, and depilatory, may improve cosmesis.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Acupuncture assists with cycle normalization and weight loss.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Follow-up at 6-month intervals to evaluate response to therapy and to monitor weight as well as medication side effects.

### *Patient Monitoring*

- Counsel patient about the risk of endometrial and breast carcinoma, insulin resistance, and diabetes, as well as obesity and its role in infertility.
- See patient frequently throughout the menstrual cycle, depending on which drug combination is used to induce ovulation.

### *DIET*

In overweight patients, weight loss is the most successful therapy because it improves cardiovascular risk, insulin sensitivity, and menstrual patterns: Counsel on lifestyle dietary changes; consider referral to nutritionist and weight center.

### *PATIENT EDUCATION*

- Provide patient with information about PCOS, such as from <http://www.acog.org/>.
- Discuss the chronic nature of this condition and the risks and benefits and side effects of

potential treatments.

- Review the importance of weight loss, if applicable. Modest weight loss of 5-10% of initial body weight has been demonstrated to improve many of the features of PCOS.

## PROGNOSIS

- Fertility prognosis is good but may need assisted reproductive technologies.
- Proper follow-up and screening can prevent endometrial carcinoma.
- Early detection of diabetes may decrease morbidity and mortality associated with cardiovascular risk factor.

## COMPLICATIONS

- Reproductive: infertility
- Metabolic: insulin resistance, diabetes mellitus, cardiovascular disease
- Psychosocial: increased anxiety, mood disorder, eating disorder, depression

## See Also

&NA;

Algorithm: Amenorrhea, Secondary

## Codes

&NA;

## ICD10

- E28.2 Polycystic ovarian syndrome
- L68.0 Hirsutism

## Clinical Pearls

&NA;

- In the United States, 40% of women with PCOS are not obese.
- Chronic anovulation should be treated because chronic estrogen stimulation in absence of progesterone may lead to endometrial hyperplasia.
- Specific therapies must be individualized according to the needs and desires of each patient.

# Polycythemia Vera

Richard D. Detheridge, MD

Roger P. Holland, MD, PhD

## BASICS

### DESCRIPTION

- Polycythemia vera (PV) is a chronic myeloproliferative clonal stem cell disorder marked by increased production of red blood cells (erythrocytosis) with excessive erythroid, myeloid, and megakaryocytic elements in the bone marrow.
- Morbidity and mortality are primarily related to complications from blood hyperviscosity or thrombosis development as well as malignant transformation.
- Myelofibrosis can develop in the bone marrow, leading to progressive hepatosplenomegaly.
- Synonym(s): primary polycythemia; Vaquez disease; Waldenstrom disease; primary PV; PV rubra; polycythemia, splenomegalic; Vaquez-Osler disease

### EPIDEMIOLOGY

#### Incidence

- Predominant age: 50 to 75 years, 5% are <40 years
- Predominant sex: male > female (slightly)
- Incidence in the United States in 2012: 2.8/100,000 population of men and 1.3/100,000 population of women

#### Prevalence

In the United States in 2010, estimates ranged from 45 to 57 cases per 100,000 patients.

### ETIOLOGY AND PATHOPHYSIOLOGY

*JAK2 V617F* mutation associated with clonal proliferative disorder

#### Genetics

*JAK2 V617F* (tyrosine kinase) mutation: >97% of patients with PV have an activating mutation;

this is helpful in differentiating from secondary erythrocytosis. Homozygote carriers will have higher incidence of symptoms such as pruritus but will not have higher incidence of disease than heterozygotes.

## **RISK FACTORS**

- PV is more prevalent among Jews of Eastern European descent than other Europeans or Asians.
- Familial history is rare.

## **COMMONLY ASSOCIATED CONDITIONS**

- Budd-Chiari syndrome
- Mesenteric artery thrombosis
- Myocardial infarction
- Cerebrovascular accident or transient ischemic attack
- Venous thromboembolism and pulmonary embolism

## **DIAGNOSIS**

### **HISTORY**

- Patients may be asymptomatic or present with nonspecific complaints, including fatigue, malaise, and/or subjective weakness.
- Erythromelalgia (burning pain of feet/hands, occasionally with erythema, pallor, cyanosis, or paresthesias)
- Arterial and venous occlusive events
- Headaches
- Blurred vision or blind spots
- Pruritus, especially after the shower
- Spontaneous bruising/bleeding
- Peptic ulcer disease (due to alterations in gastric mucosal blood flow)
- Bone pain (ribs and sternum)
- Tinnitus

## **PHYSICAL EXAM**

- Hypertension

- Facial plethora
- Splenomegaly
- Hepatomegaly
- Bone tenderness (especially ribs and sternum)
- Skin excoriations from significant pruritus
- Gouty tophi or arthritis

## *DIFFERENTIAL DIAGNOSIS*

- Secondary polycythemia
- Hemoglobinopathy
- Ectopic erythropoietin production
- Spurious polycythemia

## *DIAGNOSTIC TESTS & INTERPRETATION*

CBC; if suspicion is high, then obtain erythropoietin level and gene testing for *JAK2 V617F*.

### *Initial Tests (lab, imaging)*

- 2008 World Health Organization diagnostic criteria requires two major criteria and one minor or the first major criterion with two minor criteria (1).
  - Major criteria:
    - Hemoglobin (Hgb) >18.5 g/dL (men); Hgb >16.5 g/dL (women); or Hgb >17 g/dL (men) or Hgb >15 g/dL (women) if associated with a sustained increase of  $\geq 2$  g/dL from baseline that cannot be attributed to correction of iron deficiency.
    - Presence of *JAK2 V617F* or similar mutation
  - Minor criteria:
    - Bone marrow trilineage myeloproliferation
    - Subnormal serum erythropoietin level
    - Endogenous erythroid colony (EEC) growth
- Diagnosis can be made reliably based on clinical symptoms, presence of *JAK2 V617F* mutation, and low EPO (2).
- Other lab findings that are common but not specific

- Hyperuricemia
- Hypercholesterolemia
- Elevated serum vitamin B<sub>12</sub> levels
- CT or US to assess for splenomegaly, although not necessary for diagnosis
- Causes of secondary erythrocytosis:
  - Sleep apnea
  - Emphysema
  - Cigarette smoking
  - Renal artery stenosis
  - Carbon monoxide poisoning

### *Diagnostic Procedures/Other*

- Bone marrow aspiration shows increased cellularity.
- Cytogenetic testing (*JAK2 V617F*)

### *Test Interpretation*

- If *JAK2 V617F* mutation testing is negative and the erythropoietin level is normal or high, then PV is excluded; investigate causes of secondary erythrocytosis.
- Other causes of erythrocytosis such as ectopic erythropoietin production from a renal tumor, hypoxia from chronic lung, or cyanotic heart disease can be excluded with low or undetectable serum erythropoietin level and normal oxygen saturation.

## **TREATMENT**

### **GENERAL MEASURES**

- Risk factors: age, disease duration, disease phenotype, complications, disease activity
- Phlebotomy and low-dose aspirin is first-line therapy for low-risk patients.
- Phlebotomy reduces the blood hyperviscosity, improve platelet functions, restore systemic pressures, and decrease risk of thrombosis.
- Phlebotomy:

- Reduce hematocrit to <45%; will significantly lower the rate of cardiovascular death and major thrombosis (3)[A].
- Performed as often as every 2 to 3 days until normal hematocrit reached; phlebotomies of 250 to 500 mL. Reduce to 250 to 350 mL in elderly patients or patients with cerebrovascular disease.
- May require concurrent myelosuppressive agent if at high risk for thrombosis
- Complications of phlebotomy: chronic iron deficiency (symptomatology: pica, angular stomatitis, and glossitis), possible muscle weakness, and dysphagia
- Other therapies:
  - Maintain hydration.
  - Pruritus therapy: H<sub>1</sub> and H<sub>2</sub> blockers, ataractics
  - Uric acid reduction therapy

## MEDICATION

### First Line

- Primary therapies:
  - Low-dose aspirin 81 mg PO has been associated with a statistically nonsignificant reduction in the risk of fatal thrombotic events without increasing bleeding complications when used in conjunction with phlebotomy (4)[A].
  - Hydroxyurea is recommended for patients at high risk for thrombosis (age >60 years or history of thrombotic event) and with splenomegaly and hepatomegaly. Common starting dose 500 to 1,500 mg PO daily, titrating to control hematocrit and platelet count. Be aware that hydroxyurea can lead to higher risk of leukemic transformation (5)[A].
  - Radioactive phosphorous (<sup>32</sup>P) may control Hgb level and platelet count by destroying overactive marrow cells. May take up to 3 months before affecting cells. Consider for patients intolerant or nonadherent to hydroxyurea or short expected survival due to mutagenic potential.
  - Tyrosine kinase inhibitor imatinib 400 to 800 mg daily was shown to have moderate cytoreductive effects in PV (6)[B].
  - Pegylated interferon-*α*-2a is effective in controlling erythrocytosis, although dosing is generally limited secondary to intolerable side effects (7)[B].

Refer to hematologist/oncologist for further dosing and instructions.

- Symptomatic/adjunctive:
  - Allopurinol 300 mg/day PO for uric acid reduction
  - Cyproheptadine 4 to 16 mg PO daily as needed for pruritus
  - H<sub>2</sub>-receptor blockers or antacids for GI hyperacidity; cimetidine is also used for pruritus.
  - SSRIs (paroxetine or fluoxetine) have shown some efficacy in controlling pruritus.
  - Ultraviolet light may help with pruritus.

## *Second Line*

Myelosuppression: chlorambucil or busulfan; busulfan at 2 to 4 mg daily may be effective option for elderly patients with advanced PV refractory or intolerant to hydroxyurea, but significant rate of transformation was observed.

## *ISSUES FOR REFERRAL*

Referral to a hematologist to assist in diagnosis and management

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

Monitor hematocrit often and phlebotomize as needed to maintain target goal.

### *DIET*

- Avoid high-sodium diet, can cause fluid retention.
- Avoid iron supplement, a permissive chronic state of iron deficiency can help decrease blood production.

## *PATIENT EDUCATION*

- Perform leg and ankle exercises to prevent clots.
- Continuous education regarding possible complications and seeking treatment early for any change or increase in symptoms

## PROGNOSIS

- PV cannot be cured but can be controlled with treatment.
- Survival is >15 years with treatment.
- Patients are at risk for developing postpolycythemic myelofibrosis (PPMF) and an increased risk of malignant transformation.

## COMPLICATIONS

- Splenomegaly or hepatomegaly
- Budd-Chiari syndrome
- Vascular thrombosis (major cause of death)
- Transformation to acute leukemia
- Transformation to myelofibrosis
- Hemorrhage
- Peptic ulcer
- Uric acid stones
- Secondary gout
- Increased risk for complications and mortality from surgical procedures. Assess risk/benefits and ensure optimal control of disorder before any elective surgery.

## See Also

&NA;

Myeloproliferative Neoplasms

## Codes

&NA;

## ICD10

- D45 Polycythemia vera
- D75.1 Secondary polycythemia

## Clinical Pearls

&NA;

- *JAK2* mutations are an important component of myeloproliferative disorders.
- Common complications include thrombosis, malignant transformation, and myelofibrosis.

- Phlebotomy is first-line treatment, and consultation with an experienced hematologist is recommended.

# Polymyalgia Rheumatica

Ronald G. Chambers Jr., MD, FAAFP

Megan Babb, DO

## BASICS

### DESCRIPTION

- A clinical syndrome characterized by pain and stiffness (a term often used interchangeably by patients) of the shoulder, hip girdles, and neck (1).
- Primarily impacts the elderly, associated with morning stiffness and elevated markers of inflammation
- System(s) affected: musculoskeletal, hematologic/lymphatic/immunologic
- Synonym(s): senile rheumatic disease; polymyalgia rheumatica syndrome; pseudo-polyarthrite rhizomŽlique

### Geriatric Considerations

- Incidence increases with age
- Average age of onset ÷ 70 years

### Pediatric Considerations

Rare in patients <50 years of age; peak incidence between 70 and 80 years of age (2)

## EPIDEMIOLOGY

### Incidence

- Incidence increases after 50. Incidence of PMR is 50/100,000 and incidence of giant cell arteritis (GCA) is 18/100,000 people in the United States.
- Predominant sex: female > male (2 to 3:1) (3)
- Most common in Caucasians, especially those of northern European ancestry

### Prevalence

Prevalence in population >50 years old: 700/100,000

## ETIOLOGY AND PATHOPHYSIOLOGY

- Unknown. Symptoms appear to be related to enhanced immune system activity and periarticular inflammatory activity.
- Pathogenesis
  - Polygenic; multiple environmental and genetic factors contribute
  - Histologic evidence of GCA and parvovirus B19 DNA in temporal artery specimen

### Genetics

Associated with human leukocyte antigen determinants (HLA-DRB1\*04 and DRB1\*01 alleles) (4)

## RISK FACTORS

- Age >50 years
- Presence of GCA

## COMMONLY ASSOCIATED CONDITIONS

GCA (temporal arteritis) may occur in 15-30% of patients; more common in females than males with PMR.

## DIAGNOSIS

### HISTORY

- Suspect PMR in elderly patients with new onset of proximal limb pain and stiffness (neck, shoulder, hip).
- Difficulty rising from chair or combing hair are signs of proximal muscle involvement.
- Nighttime pain
- Difficulty arising from a chair or raising the arms
- Systemic symptoms in ~25% (fatigue, weight loss, low-grade fever)

## PHYSICAL EXAM

- Decreased range of motion (ROM) of shoulders, neck, and hips
- Muscle strength is usually normal, although it may be limited by pain and/or stiffness.

- Muscle tenderness
- Disuse atrophy
- Synovitis of the small joints and tenosynovitis
- Coexisting carpal tunnel syndrome

## *DIFFERENTIAL DIAGNOSIS*

- Rheumatoid arthritis
- Palindromic rheumatism
- Late-onset seronegative spondyloarthropathies (e.g., psoriatic arthritis, ankylosing spondylitis)
- Systemic lupus erythematosus; Sjögren syndrome; fibromyalgia
- Polymyositis/dermatomyositis (check creatine phosphokinase, aldolase)
- Thyroid disease
- Hyperparathyroidism, hypoparathyroidism
- Hypovitaminosis D
- Viral myalgia
- Osteoarthritis
- Rotator cuff syndrome; adhesive capsulitis
- Remitting seronegative symmetrical synovitis with pitting edema (RS3PE) syndrome
- Occult infection or malignancy (e.g., lymphoma, leukemia, myeloma, solid tumor)
- Myopathy (e.g., steroid, alcohol, electrolyte depletion)
- Depression

## *DIAGNOSTIC TESTS & INTERPRETATION*

Consider PMR in patients >50 years of age with proximal muscle pain and stiffness.

- Temporal artery biopsy if symptoms of GCA are present
- ESR (Westergren) elevation >40 mm/hr
  - ESR is typically elevated, sometimes >100 mm/hr
  - ESR normal (<40 mm/hr) in 7-22% of patients
- Elevated C-reactive protein

Normochromic/normocytic anemia

- Anticyclic citrullinated peptide (anti-CCP) antibodies usually negative (in contrast to elderly-onset rheumatoid arthritis [RA])
- Rheumatoid factor: usually negative (5-10% of patients >60 years of age will have positive rheumatoid factor without RA)
- Mild elevations in liver function tests, especially alkaline phosphatase
- Antibodies to ferritin peptide
- Drugs that may alter lab results: prednisone
- Disorders that may alter lab results: other disorders causing elevation of the sedimentation rate (e.g., infection, neoplasm, renal failure)
- Normal EMG
- Normal muscle histology

### *Initial Tests (lab, imaging)*

- ESR (usually >40 mm/hr); C-reactive protein; CBC
- MRI is not necessary for diagnosis but may show periarticular inflammation, tenosynovitis, and bursitis.
- US may show bursitis, tendinitis, and synovitis.
- MRI, PET, and temporal artery US may all play a role in diagnosis of PMR.

### *Diagnostic Procedures/Other*

A temporal artery biopsy is indicated in patients with symptoms suggestive of GCA. Treat empirically pending biopsy results.

### *Test Interpretation*

Scoring algorithm: morning stiffness >45 minutes (2 points), hip pain/limited ROM (1 point), absence of rheumatoid factor and anti-citrullinated protein antibody (ACPA) (2 points), and absence of peripheral joint pain (1 point). A score of >4 has 68% sensitivity and 78% specificity which increase with a positive temporal artery US.

## **TREATMENT**

### *GENERAL MEASURES*

- Address risk of steroid-induced osteoporosis.
  - Obtain dual energy x-ray absorptiometry and check 25-OH vitamin D levels if necessary.
  - Consider antiresorptive therapies (bisphosphonates) based on recommendations for treatment of corticosteroid-induced osteoporosis.
- Encourage adequate calcium (1,500 mg/day) and vitamin D (800 to 1,000 U/day) supplementation.
- Physical therapy for ROM exercises, if needed

## MEDICATION

### *First Line*

- Prednisone: 10 to 20 mg/day PO initially; expect a dramatic (diagnostic) response within days. 15 mg/day is an effective dose in most patients.
  - Increase to 20 mg/day if no immediate response.
  - If no response to 10 to 20 mg/day within a week, reconsider diagnosis.
- Divided-dose steroids (BID or TID) may be helpful (especially if symptoms recur in the afternoon).
- Consider using delayed-release prednisone at bedtime (may be more efficient in treating morning stiffness)
- Begin slow taper by 2.5 mg decrements every 2 to 4 weeks to a dose of 7.5 to 10 mg/day. Below this dose, taper by 1 mg/month to prevent relapse.
- Increase prednisone for recurrence of symptoms (relapse common).
- Corticosteroid treatment often lasts at least 1 to 2 years.
- May stop steroids at 6 to 12 months if patient is symptom-free and there is a normal ESR
- Contraindications
  - Use steroids with caution in patients with chronic heart failure, diabetes mellitus, immunocompromised conditions, and with systemic fungal or bacterial infection.
  - Treat infections concurrently.
- Precautions
  - Long-term steroid use (>2 years) is associated with sodium and water retention, exacerbation of chronic heart failure, hypokalemia, increased susceptibility to infection, osteoporosis, fractures, hypertension, cataracts, glaucoma, avascular necrosis, depression,

and weight gain

- Patients may develop temporal arteritis while on low-dose corticosteroid treatment for PMR. This requires an increase in dose to 40 to 60 mg.
- Alternate-day steroids are not effective.

## *Second Line*

- NSAIDs usually are not adequate for pain relief.
- Methotrexate has a modest effect in reducing relapse rate and lowering the cumulative dose of steroid therapy.
- There is conflicting evidence for antitumor necrosis factor agents (anti-TNF) (infliximab, etanercept) regarding steroid-sparing effects.
- Anti-interleukin (anti-IL) 6 therapy is under investigation for future use (5).
- Corticosteroid injections may reduce pain and stiffness and allow for increased levels of activity.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Evaluate patients monthly initially and during medication taper; every 3 months otherwise.
- Follow ESR as steroids are tapered; both ESR and CRP should decline as symptoms improve.
- Follow-up for symptoms of GCA (e.g., headache, visual loss, and diplopia) and report immediately.
- Monitor side effects of corticosteroid therapy such as osteoporosis, hypertension, and hyperglycemia.
- Do not treat elevated ESR (do not increase the steroid dose to normalize the ESR If patient is asymptomatic).

#### *DIET*

- Regular diet
- Aim for adequate calcium and vitamin D.

## PATIENT EDUCATION

- Review adverse effects of corticosteroids.
- Discuss the symptoms of GCA and instruct the patient to report them immediately should any occur.
- Contact physician if symptoms recur during steroid taper.
- Instruct patients to not discontinue steroids abruptly.
- Counsel patients on calcium and vitamin D requirements.
- Resources for patients
  - Arthritis Foundation: <http://www.arthritis.org/>
  - American College of Rheumatology: <http://www.rheumatology.org/I-Am-A/Patient-Caregiver/Diseases-Conditions/Polymyalgia-Rheumatica>

## PROGNOSIS

- Most patients require at least 2 years of corticosteroid treatment.
- Prognosis is very good with proper treatment.
- Relapse is common (in 25-50% of patients), particularly if steroids are tapered too quickly.
- Higher age at diagnosis, female sex, high baseline ESR, increased plasma viscosity, increased levels of soluble IL-6 receptor, or high initial steroid dose have been associated with a prolonged disease course and greater number of disease flares.

## COMPLICATIONS

- Complications related to chronic steroid use
- Exacerbation of disease with taper of steroids; development of GCA (may occur when PMR is being treated adequately)

## REFERENCES

## Codes

**&NA;**

### ICD10

- M35.3 Polymyalgia rheumatica
- M31.5 Giant cell arteritis with polymyalgia rheumatica

## Clinical Pearls

**&NA;**

- Consider PMR in patients >50 years of age presenting with proximal limb (hip, neck, shoulder) pain and stiffness.
- A normal ESR does not exclude PMR.
- If there is not a dramatic and rapid response to steroids, reconsider the diagnosis.
- Adjust steroid dosing according to patient symptoms, not the ESR.

# Polymyositis/Dermatomyositis

Christopher M. Wise, MD

## BASICS

### DESCRIPTION

- Systemic connective tissue disease characterized by inflammatory and degenerative changes in proximal muscles, sometimes accompanied by characteristic skin rash
  - If skin manifestations (Gottron sign [symmetric, scaly, violaceous, erythematous eruption over the extensor surfaces of the metacarpophalangeal and interphalangeal joints of the fingers]; heliotrope [reddish violaceous eruption on the upper eyelids]) are present, it is designated as dermatomyositis.
  - Different types of myositis include the following (1):
    - Idiopathic polymyositis
    - Idiopathic dermatomyositis
    - Polymyositis/dermatomyositis as an overlap (usually with lupus or systemic sclerosis or as part of mixed connective-tissue disease)
    - Myositis associated with malignancy
    - Necrotizing autoimmune myositis (often statin-associated) (2)
    - HIV-associated myopathy
- Inclusion-body myositis (IBM), a variant with atypical patterns of weakness and biopsy findings
- System(s) affected: cardiovascular, musculoskeletal, pulmonary, skin/exocrine
- Synonym(s): myositis; inflammatory myopathy; antisynthetase syndrome (subset with certain antibodies)

### EPIDEMIOLOGY

#### Incidence

- Estimated at 1.2 to 19/million population/year (3)
- Predominant age: 5 to 15 years, 40 to 60 years, peak incidence in mid-40s

- Predominant sex: female > male (2:1)

## *Prevalence*

2.4 to 33.8 patients/100,000 population (3)

## *Geriatric Considerations*

Elderly patients with myositis or dermatomyositis are at increased risk of neoplasm.

## *Pediatric Considerations*

Childhood dermatomyositis is likely a separate entity associated with cutaneous vasculitis and muscle calcifications.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Inflammatory process, mediated by T cells and cytokine release, leading to damage to muscle cells (predominantly skeletal muscles)
- In patients with IBM, degenerative mechanisms may be important.
- Unknown; potential viral, genetic factors

## *Genetics*

Mild association with human leukocyte antigen (HLA)-DR3, HLA-DRw52

## **RISK FACTORS**

Family history of autoimmune disease (e.g., systemic lupus, myositis) or vasculitis

## **COMMONLY ASSOCIATED CONDITIONS**

- Malignancy (in 15-25%)
- Progressive systemic sclerosis
- Vasculitis
- Systemic lupus erythematosus (SLE)
- Mixed connective tissue disease

## **DIAGNOSIS**

### **HISTORY**

- Symmetric proximal muscle weakness (1) causing difficulty when
  - Arising from sitting or lying positions
  - Climbing stairs
  - Raising arms
- Joint pain/swelling
- Dysphagia
- Dyspnea
- Rash on face, eyelids, hands, arms

## *PHYSICAL EXAM*

### Proximal muscle weakness

- Shoulder muscles
- Hip girdle muscles (trouble standing from seated or squatting position, weak hip flexors in supine position)
- Muscle swelling, stiffness, induration
- Distal muscle weakness is seen only in patients with IBM.
- Rash over face (eyelids, nasolabial folds), upper chest, dorsal hands (especially knuckle pads), fingers (Òmechanic's handsÓ)
- Periorbital edema
- Calcinosis cutis (childhood cases)
- Mesenteric arterial insufficiency/infarction (childhood cases)
- Cardiac impairment; arrhythmia, failure

## *DIFFERENTIAL DIAGNOSIS*

- Vasculitis
- Progressive systemic sclerosis
- SLE
- Rheumatoid arthritis
- Muscular dystrophy
- Eaton-Lambert syndrome
- Sarcoidosis

- Amyotrophic lateral sclerosis
- Endocrine disorders
  - Thyroid disease
  - Cushing syndrome
- Infectious myositis (viral, bacterial, parasitic)
- Drug-induced myopathies:
  - Cholesterol-lowering agents (statins)
  - Colchicine
  - Corticosteroids
  - Ethanol
  - Chloroquine
  - Zidovudine
- Electrolyte disorders (magnesium, calcium, potassium)
- Heritable metabolic myopathies
- Sleep-apnea syndrome

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Diagnosis of muscle component (myositis) usually relies on four findings:
  - Weakness
  - Creatine kinase (CK) and/or aldolase elevation
  - Abnormal electromyogram (EMG)
  - Findings on muscle biopsy
- Presence of compatible skin rash of dermatomyositis

### *Initial Tests (lab, imaging)*

- Increased CK, aldolase
- Increased serum AST (aspartate aminotransferase)
- Increased LDH (lactate dehydrogenase)
- Myoglobinuria

- Increased ESR
- Positive rheumatoid factor (<50% of patients)
- Positive antinuclear antibody (ANA) (>50% of patients)
- Leukocytosis (<50% of patients)
- Anemia (<50% of patients)
- Hyperglobulinemia (<50% of patients)
- Anti-HMGCR (3-hydroxy-3-methylglutaryl-coenzyme A reductase) seen in patient with statin-associated necrotizing autoimmune myositis
- Myositis-specific antibodies (antisyntetase antibodies) described in a minority of patients:
  - Anti-Jo-1 is the most common but has been found in <20% of patients.
  - Associated with an increased incidence of interstitial lung disease
- Chest radiograph as part of initial evaluation to assess for associated pulmonary involvement or malignancy

### *Follow-Up Tests & Special Considerations*

- Changes in muscle enzymes (CK or aldolase) correlate with improvement and worsening.
- MRI to assess muscle edema and inflammation may be used in some patients to determine best biopsy site or response to therapy.

### *Diagnostic Procedures/Other*

- EMG: muscle irritability, low-amplitude potentials, polyphasic action potentials, fibrillations
- Muscle biopsy (deltoid or quadriceps femoris)

### *Test Interpretation*

- Microscopic findings:
  - Muscle fiber degeneration
  - Phagocytosis of muscle debris
  - Perifascicular muscle fiber atrophy
  - Inflammatory cell infiltrates in adult form
  - Via electron microscopy: inclusion bodies (IBM only)

Sarcoplasmic basophilia

- Muscle fiber increased in size
- Vasculopathy (childhood polymyositis/dermatomyositis)

## TREATMENT

### GENERAL MEASURES

General evaluation for malignancy in all adults, particularly with dermatomyositis, at initial evaluation and during follow up

### MEDICATION

#### *First Line*

- Prednisone
  - 40 to 80 mg/day PO in divided doses (4)[B]
  - Consolidate doses and reduce prednisone slowly when enzyme levels are normal.
  - Probably need to continue 5 to 10 mg/day for maintenance in most patients.
- For steroid-refractory or steroid-dependent patients: azathioprine 1 mg/kg PO (arthritis dose) once daily or BID
  - Methotrexate 10 to 25 mg PO weekly, useful in most steroid-resistant patients

---

P.829

- Rash of dermatomyositis may require topical steroids or oral. hydroxychloroquine.
- Patients with IBM have very poor response to steroids and other first- and second-line drugs in general.

#### *Second Line*

- Other immunosuppressant drugs (e.g., cyclophosphamide, chlorambucil, cyclosporine, mycophenolate, tacrolimus) can be added to steroids.
- Combination methotrexate and azathioprine also may be useful in refractory cases.
- IVIG (5)[B] and rituximab (6)[B] have been reported to be helpful in a small series of patients with refractory disease.
- Contraindications: Methotrexate is contraindicated with previous liver disease, alcohol use,

pregnancy, and underlying renal disease (use with extreme caution in patients with serum creatinine >1.5 mg/dL in general).

- Precautions
  - Prednisone: Adverse effects associated with long-term steroid use include adrenal suppression, sodium and water retention, hypokalemia, osteoporosis, cataracts, and increased susceptibility to infection.
  - Azathioprine: Adverse effects include bone marrow suppression, increased liver function tests, and increased risk of infection.
  - Methotrexate: Adverse effects include stomatitis, bone marrow suppression, pneumonitis, and risk of liver fibrosis and cirrhosis with prolonged use.

## *ISSUES FOR REFERRAL*

- Diagnostic uncertainty, usually related to elevated muscle enzymes without typical symptoms of findings of muscle weakness
- Poor response to initial steroid therapy
- Excessive steroid requirement (unable to taper prednisone to <20 mg/day after 4 to 6 months)

## *SURGERY/OTHER PROCEDURES*

None indicated, other than initial biopsy

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Inability to stand, ambulate
- Respiratory difficulty
- Fever or other signs of infection
- Inpatient evaluation seldom needed

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- Follow muscle enzymes along with muscle strength and functional capacity.

- Monitor for steroid-induced complications (e.g., hypokalemia, hypertension, and hyperglycemia).
- Bone densitometry and consideration of calcium, vitamin D, and bisphosphonate therapy
- If azathioprine, methotrexate, or other immunosuppressant is used, appropriate laboratory monitoring should be done periodically (e.g., hematology, liver enzymes, and creatinine).
- Attempt to decrease and/or discontinue steroid dose as patient responds to therapy.
- Maintain immunosuppression until patient's muscle strength stabilizes for prolonged period depending on individual patient parameters, risks of medication, risk of relapse; time period undefined (months, years).

## *DIET*

Moderation of caloric and sodium intake to avoid weight gain from corticosteroid therapy.

## *PATIENT EDUCATION*

- Curtail excess physical activity in early phases when muscle enzymes are markedly elevated.
- Emphasize range-of-motion exercises.
- Gradually introduce muscle strengthening when muscle enzymes are normal or improved and stable (7)[B].

## *PROGNOSIS*

- Residual weakness: 30%
- Persistent active disease: 20%
- 5-year survival 65-75%, but mortality is 3-fold higher than general population (8,9).
- Survival is worse for women and African Americans and those with dermatomyositis, IBM, or cancer.
- Most patients improve with therapy.
- Patients with IBM respond poorly to most therapies (10).
- 20-50% have full recovery.

## **COMPLICATIONS**

- Pneumonia
- Infection
- Myocardial infarction

- Carcinoma (especially breast, lung)
- Severe dysphagia
- Respiratory impairment due to muscle weakness, interstitial lung disease
- Aspiration pneumonitis
- Steroid myopathy
- Steroid-induced diabetes, hypertension, hypokalemia, osteoporosis

## Codes

**&NA;**

### ICD10

- M33.20 Polymyositis, organ involvement unspecified
- M33.90 Dermatopolymyositis, unspecified, organ involvement unspecified
- M33.92 Dermatopolymyositis, unspecified with myopathy

## Clinical Pearls

**&NA;**

- Corticosteroids alone may be sufficient in patients who have rapid improvement in weakness and muscle enzymes. However, most patients require azathioprine, methotrexate, or other immunosuppressive medications.
- The risk of associated malignancy is higher in patients >50 years and in those with cutaneous manifestations.
- Elevated muscle enzymes (e.g., CK and aldolase) are seen frequently as transient phenomena in patients with febrile illness and injuries; may return to normal on repeat.
- In patients with persistently elevated muscle enzymes and symptoms and findings of muscle weakness, EMG followed by muscle biopsy should be the initial studies considered.
- Suspect IBM in older patients with very slow onset and progression of symptoms, poor response to steroids and immunosuppressive therapy, and atypical patterns (asymmetric, sometimes distal) of muscle weakness.
- Suspect autoimmune necrotizing myositis in patients who develop myopathy while taking lipid-lowering drugs (statins) but fail to improve or worsen after withdrawal of statin therapy.

# Popliteal (Baker) Cyst

Shane L. Larson, MD

## BASICS

### DESCRIPTION

- A fluid-filled synovial sac arising in the popliteal fossa as a distention of (typically) the gastrocnemial-semimembranous bursa. Not a true cyst
- Can be unilateral or bilateral
- Most frequent cystic mass around the knee (1)
- Primary cysts are a distention of the bursa (arise independently without an intra-articular disorder).
- Secondary cysts occur if there is a communication between the bursa and knee joint, allowing articular fluid to fill the cyst.
- Associated with synovial inflammation

### EPIDEMIOLOGY

#### Incidence

- Bimodal distribution
  - Children ages 4 to 7 years
  - Adults increasing with age
- Primary cysts usually seen in children <15 years
- Secondary cysts seen in adults

#### Prevalence

- Variable adult prevalence of 19-47% in symptomatic knees and 2-5% in asymptomatic knees.
- In children: 6.3% in symptomatic knees; 2.4% in asymptomatic knees

### ETIOLOGY AND PATHOPHYSIOLOGY

Associated intra-articular pathology includes

- Meniscal tears, mostly of the posterior horn
- Anterior cruciate ligament (ACL) insufficiency
- Degenerative articular cartilage lesions
- Rheumatoid arthritis (20%)
- Osteoarthritis (50%)
- Osteochondritis
- Gout (14%)
- Other potential factors
  - Infectious arthritis
  - Polyarthritis
  - Villonodular synovitis
  - Lymphoma
  - Sarcoidosis
  - Connective tissue diseases (2)
- Extension or herniation of synovial membrane of the knee joint capsule or connection of normal bursa with the joint capsule
- May result from increased intra-articular pressure
- Commonly seen with knee effusions
- Direct trauma to the bursa is likely the primary cause in children because of no communication between the bursa and the joint.
- A valve-like mechanism allowing one-way passage of fluid from the joint to the bursal connection has been described.

## ***RISK FACTORS***

- Osteoarthritis of knee (most common) (3)[B]
- Rheumatoid arthritis
- Meniscal degeneration or tear
- Advancing age
- Ligamentous insufficiency

## COMMONLY ASSOCIATED CONDITIONS

Any condition causing knee joint effusion

## DIAGNOSIS

### HISTORY

- Painless mass arising in the popliteal fossa
- Most cysts are asymptomatic.
- Dull ache if cyst is large enough to impede joint motion—typically a restriction of flexion
- Painful if cyst ruptures
- Large cysts may cause entrapment neuropathy of the tibial nerve.
- Vascular compression, most commonly of the popliteal vein, may produce claudication or thrombophlebitis.
- Activity alters the cyst size.

### PHYSICAL EXAM

- Examine in full extension and 90 degrees of flexion.
- Foucher sign: Mass increases with extension and disappears with flexion.
- Most commonly found in medial aspect of popliteal fossa lateral to the head of the gastrocnemius and medial to the neurovascular bundle
- Cyst is easiest to palpate when knee is slightly flexed and may occasionally be fluctuant or tender.
- Transillumination helps distinguish cyst from solid mass.
- Ruptured cysts are typically painful with associated swelling and bruising over the ipsilateral calf and ankle at the medial malleolus (Crescent sign).
- Ruptured cysts also are associated with pseudothrombophlebitis, and rarely, compartment syndrome (5).

### DIFFERENTIAL DIAGNOSIS

- Infection/abscess
- Lipoma, liposarcoma

- Fibroma, fibrosarcoma
- Hematoma
- Deep venous thrombosis
- Vascular tumor
- Popliteal vein varices
- Xanthoma
- Aneurysm (rare)
- Ganglion cyst
- Thrombophlebitis
- Muscular herniation (rare, related to trauma)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- CBC, ESR (if septic arthritis suspected)
- Ensure not a popliteal aneurysm prior to aspiration. Send aspirate for cell count and culture to determine if fluid is infectious, inflammatory, or mechanical.
- Ultrasound confirms presence and size; Doppler, can differentiate Baker cysts from popliteal vessel aneurysms, DVT, or soft tissue tumors (4).
- MRI helps assess derangements of internal joint structures and to identify cyst leakage.

### ***Follow-Up Tests & Special Considerations***

- Consider observation over invasive testing in children.
- Radiographs may show soft tissue density posteriorly.

P.831

- Arthrography may demonstrate communication with joint capsule or rupture.
- CT arthrography is superior for visualizing cystic details and can help distinguish lipomas, aneurysms, and malignancies from cysts.

## **TREATMENT**

### ***GENERAL MEASURES***

- No treatment if asymptomatic
- Treat any associated underlying conditions.
- Compressive wrap or sleeve for comfort.

## **MEDICATION**

If etiology is identified from cellular fluid examination, treat the underlying condition.

### *First Line*

Analgesics and NSAIDs for symptomatic relief

## **ADDITIONAL THERAPIES**

- Physical therapy improves knee ROM and strength, particularly with coexisting pathology.
- Temporary relief with needle aspiration; recurrence common
- Improvement in joint ROM, knee pain, swelling, accompanied reduction in bursa size after aspiration, and intra-articular/intracystic corticosteroid injection (6)[B]
- A combination of physical therapy and corticosteroid injection leads to best improvements in pain, function, and reduction in cyst size (7)[A].
- Sclerotherapy injections of ethanol or dextrose/sodium morrhuate shown to have good results in small studies (8)[B].

## **SURGERY/OTHER PROCEDURES**

- Consider excision when symptoms persist despite treatment or no etiology is found.
- Surgery usually not required in children
- Recurrence after standard surgery is common and is highest if chondral lesions are present.
- Arthroscopic surgery is highly successful if a valvular mechanism is identified and intra-articular pathology is treated (9,10)[B].
- A modified surgical technique in children has proved effective without recurrence (11)[B].
- Excision via arthroscopy or open procedure often requires concomitant treatment of underlying pathology (12)[B].

**ONGOING CARE**

# PROGNOSIS

- Variable; many cysts remain asymptomatic.
- Some cysts resolve with treatment of underlying etiology (e.g., gout, rheumatoid arthritis).
- In children, most cysts resolve without treatment.

## COMPLICATIONS

- Compartment syndrome in ruptured cyst
- Thrombophlebitis from compression of the popliteal vein
- Infection of popliteal cyst
- Hemorrhage into cyst if on anticoagulants

## See Also

&NA;

Algorithm: Knee Pain

## Codes

&NA;

### ICD10

- M71.20 Synovial cyst of popliteal space [Baker], unspecified knee
- M71.21 Synovial cyst of popliteal space [Baker], right knee

- M71.22 Synovial cyst of popliteal space [Baker], left knee

## Clinical Pearls

### &NA;

- Conservative treatment of Baker cysts is preferred in children, as most will spontaneously resolve.
- In adults, treatment of underlying cause may resolve Baker cysts.
- Pain, bruising, and swelling over the medial malleolus (crescent sign) suggests cyst rupture.

# Portal Hypertension

Walter M. Kim, MD, PhD

Jyoti Ramakrishna, MD

## BASICS

### DESCRIPTION

- Increased portal venous pressure >5 mm Hg that occurs in association with splanchnic vasodilatation, portosystemic collateral formation, and hyperdynamic circulation
- Most commonly secondary to elevated hepatic venous pressure gradient (HVPG; the gradient between portal and central venous pressures)
- Course is generally progressive, with risk of complications including acute variceal bleeding, ascites, encephalopathy, and hepatorenal syndrome.

### EPIDEMIOLOGY

#### *Incidence*

- Prevalence: <200,000 persons in the United States
- Predominant age: adult
- Predominant sex: male > female

### ETIOLOGY AND PATHOPHYSIOLOGY

- Causes generally classified as follows:
  - Prehepatic (portal vein thrombosis or obstruction)
  - Intrahepatic (most commonly cirrhosis)
  - Posthepatic (hepatic vein thrombosis, Budd-Chiari syndrome, right-sided heart failure)
- Cirrhosis accounts for 90% of intrahepatic cases; may be due to the following:
  - Virus (hepatitis B, hepatitis C, hepatitis D)
  - Alcoholism
  - Schistosomiasis

- Wilson disease
  - Hemochromatosis
  - Primary biliary cirrhosis (PBC)
  - Sarcoidosis
- Increased HVPG results in venous collateral formation in the distal esophagus, proximal stomach, rectum, and umbilicus.
  - Gastroesophageal variceal formation is found in 40% of patients with portal hypertension.
  - Progression of portal hypertension results in splanchnic vasodilation and angiogenesis.

## *Genetics*

No known genetic patterns except those associated with specific hepatic diseases that cause portal hypertension

## **RISK FACTORS**

See ÒEtiology.Ó

## *Pediatric Considerations*

In children, portal vein thrombosis is the most common extrahepatic cause; intrahepatic causes are more likely to be biliary atresia, viral hepatitis, and metabolic liver disease.

## **DIAGNOSIS**

### **HISTORY**

- Weakness/fatigue
- Jaundice
- Symptoms of heart failure including chest pain, shortness of breath, and/or edema
- Hematemesis
- Melena
- Oliguria
- History of chronic liver disease
- Alcoholic hepatitis
- Alcohol abuse

## *PHYSICAL EXAM*

- Exam findings may be general or related to specific complications.
- General
  - Pallor
  - Icterus
  - Digital clubbing
  - Palmar erythema
  - Splenomegaly
  - Caput medusa
  - Spider angiomata
  - Umbilical bruit
  - Hemorrhoids
  - Gynecomastia
  - Testicular atrophy
- Gastroesophageal varices
  - Hypotension
  - Tachycardia
- Ascites
  - Distended abdomen
  - Fluid wave
  - Shifting dullness with percussion
- Hepatic encephalopathy
  - Confusion/coma
  - Asterixis
  - Hyperreflexia

## *DIFFERENTIAL DIAGNOSIS*

Usually related to specific presentations

- Gastroesophageal varices with hemorrhage
  - Portal hypertensive gastropathy
  - Hemorrhagic gastritis
  - Peptic ulcer disease
  - Mallory-Weiss tear
- Ascites
  - Spontaneous bacterial peritonitis (SBP)
  - Pancreatic ascites
  - Peritoneal carcinomatosis
  - Tuberculous peritonitis
  - Nephrotic syndrome
  - Fluid overload from heart failure
  - Hepatic malignancy
- Hepatic encephalopathy
  - Delirium tremens
  - Intracranial hemorrhage
  - Sedative abuse
  - Uremia
- Hepatorenal syndrome
  - Drug nephrotoxicity
  - Renal tubular necrosis

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

Direct calculation of HVPG (approximation of the gradient in pressure between portal vein and IVC):

- HVPG = wedged hepatic venous pressure (WHVP)
  - free hepatic venous pressure (FHVP)

- HVPG >10, esophageal varices generally develop.
- WHVP is estimated by occlusion of the hepatic vein by a balloon catheter and measurement of the proximal static column of blood.
- FHVP is estimated by direct measurement of the patent hepatic vein, intra-abdominal inferior vena cava, or right atrium.
- Nonspecific changes associated with underlying disease:
  - Hypersplenism: anemia (also may be due to malnutrition or bleeding), leukopenia, thrombocytopenia
  - Hepatic dysfunction
    - Hypoalbuminemia
    - Hyperbilirubinemia
    - Elevated alkaline phosphatase
    - Elevated liver enzymes (AST, ALT)
    - Abnormal clotting (prothrombin time, international normalized ratio, partial thromboplastin time)
  - GI bleeding
    - Iron deficiency anemia
    - Elevated serum ammonia
    - Fecal occult blood
    - Thrombocytopenia
  - Hepatorenal syndrome
    - Elevated serum creatinine (Cr), blood urea nitrogen (BUN)
    - Urine Na <5 mEq/L (<20 mmol/L)
  - US and CT scan/MRI may detect cirrhosis, splenomegaly, ascites, and varices.
  - US/duplex Doppler
    - Can determine presence and direction of flow in portal and hepatic veins
    - Useful in diagnosing portal vein thrombosis, shunt thrombosis, or the presence of ascites
  - CT scan/MRI: angiographic measurement of hepatic venous wedge pressure via jugular or femoral vein

- Correlates with portal pressure
- Risk of variceal bleeding is increased if hepatic venous pressure gradient >12 mm Hg.
- Upper GI series may outline varices in esophagus and stomach.
- Transient elastography is an emerging method to determine hepatic fibrosis and to predict portal hypertension (1).

## *Diagnostic Procedures/Other*

Endoscopy can diagnose esophageal and gastric varices and portal hypertensive gastropathy.

## *Test Interpretation*

Specific for underlying disease

## **TREATMENT**

### *GENERAL MEASURES*

- Avoid sedatives that may precipitate encephalopathy.
- Limit sodium intake because cirrhotic patients avidly retain sodium.

### *MEDICATION*

Therapy for encephalopathy: See ÒHepatic Encephalopathy.Ó

#### *First Line*

- Prophylaxis against variceal bleeding (2,3)[A]:
  - Nonselective *&bgr;*-blockade
    - Propranolol: start with 10 to 20 mg/day PO BID to TID
    - Nadolol: 40 to 80 mg/day PO once-daily dosing
  - Doses may be titrated up as tolerated to maximum recommended doses; goal resting HR of 55 to 60 bpm

---

P.833

- Therapy for acute variceal hemorrhage:
  - Vasopressin: start with 0.2 to 0.4 U/min IV; increase to maximum dose 1 U/min as needed; pediatric dose: 0.002 to 0.005 U/kg/min; do not exceed 0.01 U/kg/min. After bleeding

stops, continue at same dose for 12 hours and then taper off over 24 to 48 hours.

- Octreotide: 50 &mgr;g IV bolus, followed by 25 to 50 &mgr;g/hr continuous infusion; pediatric dose: 1 &mgr;g/kg bolus followed by 1 &mgr;g/kg/hr is used traditionally; treat for up to 5 days.
- For prevention of recurrence and for overall reduction in mortality:
  - Propranolol: 10 to 60 mg/day PO BID to QID; pediatric dose: 0.5 to 1 mg/kg/day PO divided q6-8h
  - Nadolol: 40 to 80 mg/day PO reduces portal venous blood inflow by blocking the adrenergic dilatation of the mesenteric arterioles.
  - Tetrandrine, a calcium channel blocker, also has been found to reduce the rate of rebleeding with fewer side effects.
- Initial treatment for ascites (along with salt and fluid restriction):
  - Furosemide: 20 to 40 mg/day PO; pediatric dose: 1 to 2 mg/kg/dose PO ± IV albumin infusion
  - Spironolactone: 50 to 100 mg/day PO; pediatric dose: 1 to 3 mg/kg/day PO

## *Second Line*

- Terlipressin (2 mg IV q4h; titrate down to 1 mg IV q4h once hemorrhage is controlled; may be used for up to 48 hours) is a more selective splanchnic vasoconstrictor and may be associated with fewer complications. It is currently used when standard therapy with somatostatin or octreotide fails.
- Addition of nitrates, such as nitroglycerin or isosorbide mononitrate, reduces portal pressures and bleeding rates and has been shown to reduce mortality. Because the risk-benefit ratio is not clear, nitrates are not considered first-line treatment.
- Studies are ongoing for possible benefits of other agents including simvastatin, clonidine, verapamil, and losartan.

## *ISSUES FOR REFERRAL*

Patients with portal hypertension should be managed longitudinally by both a primary care physician and a gastroenterologist.

## *SURGERY/OTHER PROCEDURES*

- Treatments available for specific complications of portal hypertension (in addition to or if refractory to medications):

- Gastroesophageal varices with hemorrhage
  - Endoscopic variceal banding or sclerosis (the first-line treatment in many cases for acute hemorrhage) within 12 hours of presentation (4)[A]
  - Balloon tamponade (not used commonly when endoscopic treatment is available)
  - Transjugular intrahepatic portosystemic shunt (TIPS)
  - Portocaval shunting
- Ascites refractory to medical management
  - Large-volume paracentesis
  - Peritoneovenous shunt
  - TIPS
- Liver transplantation should be considered for patients with advanced disease.

## *INPATIENT CONSIDERATIONS*

- Acute GI bleeding should be managed in the inpatient setting, either on the regular medical floor if the patient is hemodynamically stable or occasionally in the ICU if the patient is unstable.
- Patients with mental status changes from encephalopathy need to be evaluated in the inpatient setting.

## *Admission Criteria/Initial Stabilization*

- Acute bleeding from the intestinal tract, either vomiting or per rectum
- Acute confusional state/mental status changes
- If acute variceal bleeding:
  - Type and cross patient's blood.
  - Initial resuscitation with isotonic fluid until packed RBCs are available
  - Correct coagulopathy with vitamin K and fresh frozen plasma (FFP).
  - Endoscopy as soon as the patient is stabilized (for diagnosis and treatment)
- Avoid sedatives that may precipitate encephalopathy.
- Limit sodium administration because cirrhotic patients avidly retain sodium.
- Restrict protein only if encephalopathic.

## **ALERT**

If the patient is an active alcohol drinker, watch for signs and symptoms of withdrawal. Follow inpatient protocols for alcohol withdrawal management.

### *IV Fluids*

Use isotonic fluid for hydration.

### *Discharge Criteria*

- For GI bleeding:
  - No active bleeding in 24 hours
  - Stable hemoglobin and hematocrit
  - Hemodynamically stable (especially heart rate)
- For encephalopathy: improvement in or resolution of mental status changes to baseline

## **ONGOING CARE**

### *DIET*

In patients with cirrhosis, sodium restriction is important because cirrhotic patients avidly retain sodium.

### *PATIENT EDUCATION*

Refrain from drinking alcohol. Resources for patients who have difficulty with not drinking alcohol can be obtained from Alcoholics Anonymous at <http://www.aa.org/>.

### *PROGNOSIS*

- Hepatic reserve defined by Child-Pugh classification: rating based on encephalopathy, ascites, bilirubin, albumin, prothrombin
- Variceal bleeding
  - 1/3 of patients with known varices will bleed eventually.
  - 50% rebleed, usually within 2 years, unless portal pressure is reduced by surgical or TIPS procedure.
  - 15-20% mortality rate
- Ascites and encephalopathy often recur.

- Prognosis of patients with ascites is poor: 50% 1-year survival without liver transplant (compared with 90% for patients with cirrhosis and no ascites)

**Codes**

&NA;

# ICD10

K76.6 Portal hypertension

## Clinical Pearls

**&NA;**

- Portal hypertension can be diagnosed based on physical examination in the setting of known risk factors, specifically cirrhosis.
- Endoscopic treatment is successful for acute variceal hemorrhage 85% of the time.
- Prognosis of patients with ascites is poor: 50% 1-year survival without liver transplant (compared with 90% for patients with cirrhosis and no ascites).
- Advantages and disadvantages of balloon tamponade for acute variceal bleed:
  - Advantages include rapid and often effective control of bleeding (30-90%) and common availability of device.
  - Disadvantages include recurrence of bleeding when balloon is deflated, patient discomfort, and risk of esophageal perforation.

# Postconcussion Syndrome (Mild Traumatic Brain Injury)

Vicki R. Nelson, MD, PhD

Christopher L. Tangen, DO

## BASICS

### DESCRIPTION

- Postconcussion syndrome (PCS) is a constellation of symptoms involving physical, cognitive, and/or behavioral symptoms that persist after a concussion (mild traumatic brain injury [MTBI]) and may continue for weeks to years (1)[C].
- It is unclear at what point postconcussive symptoms become postconcussive syndrome.
- Symptoms of PCS can include any symptom of concussion (1,2)[C]
  - Cognitive
    - Poor focus
    - Poor organization
    - Diminished academic/intellectual performance
    - Slowed response time
  - Physical
    - Headache
    - Nausea
    - Visual changes
    - Light and noise sensitivity
    - Tinnitus
    - Dizziness and balance problems
    - Fatigue and sleep disturbance
  - Behavioral

- Depression
  - Irritability/emotional lability
  - Apathy
  - Increased sensitivity to alcohol
- Diagnosis is based on history and clinical symptoms.

## EPIDEMIOLOGY

### *Incidence*

The reported range of MTBI patients who develop PCS varies widely between 5% and 80%.

- The variation is due to difficulty in differentiating postconcussion *symptoms* from postconcussion *syndrome*.
- Consensus is that 80-90% of concussion victims recover from postconcussion *symptoms* within 7 to 10 days, slightly longer in children/adolescents (3)[C].

### *Prevalence*

Predominant sex: Female > male, although female gender is not universally considered a risk factor.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Controversial; exact mechanism(s) unknown
- It is postulated that microscopic axonal injury from shearing forces leads to inflammation that causes secondary brain injury.
- There is conflicting data on structural brain damage and the correlation of imaging findings with physical symptoms (1,2,4,5,6)
- Because the pathophysiology of PCS is not well understood and because of symptom overlap with other psychiatric conditions, PCS remains a difficult condition to diagnose and to manage.
  - Only some people with MTBI develop PCS; it is unclear what causes PCS symptoms to occur and to persist (5,6).
  - Psychiatric factors are commonly associated with, and may play a role in, the development of PCS. It can be a challenge to differentiate pure psychiatric dysfunction from true PCS (1,5,6)[C],(7)[B].
  - Neuropsychiatry evaluation may be helpful to differentiate PCS from psychiatric disorders.

Patient reported high symptom burden following MTBI is associated with increased risk of PCS (8)[B].

## **RISK FACTORS**

- Amnesia, migraine, self-reported cognitive decline, noise and light sensitivity developing or worsening in the first day to weeks after MTBI (1)[C],(4)[B]
- Preexisting psychiatric disease including depression, anxiety, personality disorder, and posttraumatic stress disorder (PTSD)
- Preexisting expectation of poor outcomes in patients following concussion/MTBI (1)[C],(4)[B]
- Nonsport concussion
- Unclear if previous history of concussion(s) is a risk factor for PCS (2)[C].
- Low socioeconomic status

## **GENERAL PREVENTION**

- Education of players, coaches, parents, and athletic trainers about concussion, PCS, and following game safety rules designed to protect players.
- Head injury precautions with activities are advised, but no good evidence that these decrease incidence of MTBI or PCS.
- Early screening and intervention(s) for anxiety and depression

## **COMMONLY ASSOCIATED CONDITIONS**

- PTSD
- Anxiety/depression
- Fibromyalgia
- Personality disorders (namely, compulsive, histrionic, and narcissistic)
- *ADHD*

## **DIAGNOSIS**

### **HISTORY**

- Detailed history of recent impact/closed head injury, including the following:
  - Mechanism

Timing of injury related to symptoms

- Previous head injuries, including concussion, and timing of those injuries
- Previous medical, psychiatric, or social history
- Report of neurologic, cognitive, or behavioral symptoms by patient/family

## *PHYSICAL EXAM*

Complete neurologic exam, including the following:

- Glasgow Coma Scale (GCS)
- Anxiety/depression screening
  - Patient Health Questionnaire-9 (PHQ-9)
  - GAD-7
- Sport Concussion Assessment Tool, NFL Sideline Concussion Assessment Tool, or computerized neuropsychological (CNP) testing both pre- and post-MTBI is common practice, although data are limited on validity (3)[C]. More info regarding CNP below

## *DIFFERENTIAL DIAGNOSIS*

- Postconcussive symptoms
- PTSD
- Anxiety/depression
- Personality disorders
- Migraine headaches
- Chronic fatigue syndrome, fibromyalgia
- Evolving intracranial hemorrhage
- Exposure to toxins, including prescription and recreational drugs
- Endocrine/metabolic abnormality

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- If clinically warranted, consider evaluation for infection, intoxication, and endocrine/metabolic abnormality.
- Brain imaging both on initial evaluation of MTBI and PCS is generally neither fruitful nor

indicated.

- Imaging to evaluate for bleeding may be helpful in patients with comorbid conditions or who are taking anticoagulation therapy.
- Recommend cervical imaging when concomitant cervical spine injury is suspected.

## *Follow-Up Tests & Special Considerations*

- Several CNP testing programs can be used to guide decisions regarding return to play. If baseline testing is available, scores can be used as controls against scores achieved after MTBI.
- Formal neuropsychiatric evaluations are likely superior to CNP testing when available. None of these tests should be used alone in decision making, especially if a patient is still having symptoms despite improving or baseline scores (1,3)[C].
- Common neuropsychological testing programs for PCS
  - Immediate Post-Concussion Assessment and Cognitive Testing (ImPACT)
  - Axon Sports Computerized Cognitive Assessment Tool (CCAT)
  - Post Concussion Symptom Scale (PCSS)
  - Balance Error Scoring System (BESS)
  - Automated Neuropsychological Assessment Metrics (ANAM)

---

P.835

## **TREATMENT**

### *GENERAL MEASURES*

- Subthreshold exercise has been shown to help resolution and can start after 21 days (7)[B].
- Consider physical therapy for coexistent cervical or vestibular injury.
- Return to play
  - Persons with concussion or PCS should be restricted from sport activity until they are off all medications that may mask PCS symptoms and clinical symptoms have resolved (1,3)[C].
  - Return to full activity should progress according to step-wise concussion recommendations (1,3)[C].

### *MEDICATION*

## *First Line*

### Headache/neck pain

- Nonopioid pain control (e.g., NSAIDs)
  - Sedation may obscure cognitive evaluation.
  - Possible association with use of opiates and increased risk of anxiety/depression in PCS patients (5)[B].
  - Consider occipital nerve block.

### **ALERT**

Avoid opiates and benzodiazepines (5)[B].

- Depression/sleep disorders
  - Anxiety/depression screening starting in the first week post MTBI
    - Melatonin for sleep
    - Tricyclic antidepressants, or trazodone if there is concomitant sleep disturbance, may be beneficial.
    - SSRIs
  - Consider referral to mental health specialist(s).
- Cognitive disorders (6)
  - Evaluation by neuropsychiatrist
  - Methylphenidate may be considered (9)[A].
  - SSRIs may be considered, especially if concomitant anxiety/depression (9)[A].

## *ISSUES FOR REFERRAL*

- Neuropsychiatric therapy including comprehensive cognitive evaluation for potential TBI rehabilitation
- Cognitive behavioral therapy for anxiety and depression symptoms
- Occupational therapy for vocational rehabilitation, if needed
- Physical therapy for vestibular rehabilitation
- Neurology referral if primary care interventions for seizures, headache, vertigo, or cognition are unsuccessful.

- Substance abuse counseling, if needed

## COMPLEMENTARY & ALTERNATIVE MEDICINE

Massage therapy/osteopathic manipulative treatment for headache and neck pain

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

Schedule regular follow-up to evaluate for persistent symptoms, efficacy of/need for neuropsychiatric evaluation, and the efficacy of/need for pharmacologic therapy.

### Patient Monitoring

- Consider serial neuropsychological testing.
- Follow return to play guidelines (3)[C].

### PATIENT EDUCATION

- Centers for Disease Control and Prevention: <http://www.cdc.gov/headsup/>
- Mayo Clinic Health Information: <http://www.mayoclinic.com/health/post-concussion-syndrome/DS01020/>
- Brain Injury Association of America: <http://www.biausa.org/>; (800) 444-6443

### PROGNOSIS

- Prognosis generally is good.
- Adolescents may recover more slowly than adults.

### COMPLICATIONS

- Repeat head injury or return to play before resolution of PCS can worsen/prolong symptoms.
- Case studies of second-impact syndrome, a rare but potentially fatal condition owing to a second head injury soon after the first, have been reported.

## See Also

&NA;

Concussion (Mild Traumatic Brain Injury)

## Codes

&NA;

### ICD10

- F07.81 Postconcussional syndrome
- S06.9X0A Unsp intracranial injury w/o loss of consciousness, init
- S06.9X9A Unsp intracranial injury w LOC of unsp duration, init

## Clinical Pearls

&NA;

- Imaging rarely useful for PCS; head CT scan is the test of choice for acute injury to exclude intracranial bleeding.
- Coordinate multidisciplinary treatment plans for patients with persistent symptoms.
- Return to play/activity should not occur until symptoms return to baseline and any pre-PCS medications are optimized by the prescribing clinician.

# Posttraumatic Stress Disorder (PTSD)

Rachel Bramson, MD

Michael L. Brown, MD

Suzanne Shurtz, MLIS, AHIP

## BASICS

### DESCRIPTION

- Posttraumatic stress disorder (PTSD) is an anxiety disorder defined as a reaction that can occur after exposure to an extreme traumatic event involving death, threat of death, serious physical injury, or a threat to physical integrity.
- This reaction has three cardinal characteristics:
  - Reexperiencing the trauma
  - Avoidance of anything related to the traumatic event and/or numbing of general responsiveness
  - Increased arousal
- Traumatic events that may trigger PTSD include natural/human disasters, serious accidents, war, sexual abuse, rape, torture, terrorism, hostage-taking, or being diagnosed with life-threatening disease.
- PTSD can be:
  - Acute: symptoms lasting <3 months
  - Chronic: symptoms lasting ≥3 months
  - Delayed onset: 6 months (from event to symptom onset) in 25% of diagnosed cases

### EPIDEMIOLOGY

- ÷30% of men and women who have spent time in a war zone experience PTSD.
- Current estimates of PTSD in military personnel who served in Iraq range from 12-20%.
- 16% children and adolescents exposed to trauma develop PTSD (high in girls with interpersonal trauma 33%; low in boys with noninterpersonal trauma 8%) (1).

## *Incidence*

÷7.7 million American adults aged <sup>3</sup>18 years (3.5% of this age group) are diagnosed with PTSD each year.

## *Prevalence*

Lifetime prevalence for PTSD is 8-9%.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- During trauma, the locus coeruleus mediates sympathetic outflows to the amygdala (rapid effect) and adrenal medulla (sustained effect). The adrenal medulla then releases catecholamines, which stimulate peripheral afferent vagal *&bgr;*-receptors. Vagal afferents innervate the nucleus tractus solitarius (NTS) in the brainstem medulla. NTS fibers innervate the amygdala with norepinephrine (NE).
- With an increase in NE, the amygdala mediates coupling of emotional valence to declarative memories via long-term potentiation, forming deeply engraved trauma memories and leading to intrusive memories and emotions, potentially leading to PTSD.
- The orbitofrontal cortex (which usually exerts an inhibiting effect on this activation) appears less capable of inhibiting this activation due to stress-induced atrophy of specific nuclei in this region.

## *Genetics*

- Monozygotic twins exposed to combat in Vietnam were at increased risk of the cotwin having PTSD compared with twins who were dizygotic.
- Some data suggest an association between dopamine transporter gene (DAT) *SLC6A3 3'* (VNTR) polymorphism, and PTSD.

## **RISK FACTORS**

- Pretrauma environment:
  - Female sex
  - Younger age
  - Psychiatric history
  - Sexual abuse
- Peritrauma environment:
  - Severity of the trauma

- Peritrauma emotionality
- Perception of threat to life
- Perpetration of the trauma
- Posttrauma environment:
  - Perceived injury severity
  - Medical complications
  - Perceived social support
  - Persistent dissociation from traumatic event
- Subsequent exposure to trauma-related stimuli

## *GENERAL PREVENTION*

- There is moderate evidence for hydrocortisone (2) and some evidence for propranolol (3) reducing development of full posttraumatic syndrome.
- Compulsory psychological debriefing immediately after a trauma (critical incident stress management) does not prevent PTSD and may be harmful (4).

## *COMMONLY ASSOCIATED CONDITIONS*

- Major depressive disorder
- Alcohol/substance abuse
- Panic disorder
- Obsessive-compulsive disorder
- Agoraphobia and/or social phobia
- Traumatic brain injury
- Smoking (especially with assaultive trauma)
- Major neurocognitive disorders, dementia, or amnesia

## *Pediatric Considerations*

Oppositional defiant disorder and separation anxiety are common comorbid conditions.

**DIAGNOSIS**

## HISTORY

Diagnosis is based on *DSM-V* criteria:

- Criterion A: exposure to trauma ( 1 of the following):
  - Direct experience of a traumatic event
  - In-person witnessing of a traumatic event
  - Learning of a traumatic event involving a close friend or family member
  - Repeated exposure to details of a traumatic event
- Criterion B: intrusive symptoms associated with the traumatic event ( 1 of the following):
  - Recurrent, involuntary, and intrusive distressing memories of the event
  - Recurrent distressing dreams related to the event
  - Dissociative reactions that simulate a recurrence of the event
  - Intense or prolonged distress to stimuli that resemble an aspect of the event
- Criterion C: avoidance of stimuli associated with the trauma ( 1 of the following):
  - Avoidance of memories, thoughts, or feelings about the event
  - Avoidance of external reminders that trigger memories, thoughts, or feelings about the event
- Criterion D: negative cognitive and mood changes associated with the trauma ( 2 of the following):
  - Inability to remember aspects of event
  - Persistent and exaggerated negative opinion of self, others, or the world
  - Distorted beliefs about the cause or consequences of the event
  - Negative emotional state
  - Diminished interest in significant activities
  - Feeling detached from others
  - Inability to experience positive emotions
- Criterion E: hyperarousal ( 2 of the following):
  - Difficulty sleeping/falling asleep
  - Decreased concentration
  - Hypervigilance
  - Outbursts of anger/irritable mood

- Exaggerated startle response
- Self-destructive behavior
- Criterion F: duration of the relevant criteria symptoms should be >1 month
- Criterion G: clinically significant distress/impairment in functioning
- Criterion H: relevant criteria not attributed to substance effects or other medical conditions

### ***Pediatric Considerations***

- Memories of the traumatic event may not appear distressing and may be seen as play reenactment.
- Frightening dreams of children may not have content attributable to the traumatic event.
- Reactions can include a fear of being separated from a parent, crying, whimpering, screaming, immobility and/or aimless motion, trembling, frightened facial expressions, excessive clinging, and regressive behavior.
- Older children may show extreme withdrawal, disruptive behavior, and/or an inability to pay attention. Regressive behaviors, nightmares, sleep problems, irrational fears, irritability, refusal to attend school, outbursts of anger, fighting, somatic complaints with no medical basis, and decline in schoolwork performance are often seen. Furthermore, depression, anxiety, feelings of guilt, and emotional numbing are often present.
- Parental posttraumatic stress has been shown to be a robust predictor of pediatric PTSD (5)[A].

## ***PHYSICAL EXAM***

- Patients may present with physical injuries from the traumatic event.
- Mental status examination:
  - Thoughts and perceptions (e.g., hallucinations, delusions, suicidal ideation, phobias)
  - General appearance: disheveled, poor hygiene
  - Behavior: agitation; startle reaction extreme
  - Psychological numbness
  - Orientation may be affected.
  - Memory: forgetfulness, especially concerning the details of the traumatic event
  - Poor concentration

- Poor impulse control
- Altered speech rate and flow
- Mood and affect may be changed: depression, anxiety, guilt, and/or fear

### *Pediatric Considerations*

Elevated heart rate immediately following trauma is associated with development of PTSD (5)[A].

## **DIFFERENTIAL DIAGNOSIS**

- Acute stress disorder (symptoms <4 weeks)
- Generalized anxiety disorder
- Adjustment disorder
- Obsessive-compulsive disorder
- Schizophrenia
- Major depressive disorder
- Mood disorder with psychotic features
- Substance abuse
- Personality disorders
- Dissociative disorders
- Conversion disorder

---

P.837

## **TREATMENT**

Better prognosis if treated with a combination of psychotherapy and pharmacotherapy, initiated soon after the trauma.

## **MEDICATION**

### *First Line*

- SSRIs: depression, panic attacks, startle response, sleep disruption (6)[A]. All commonly used SSRIs have been shown to be effective in the treatment of PTSD and are the first-line treatment:
  - Sertraline: 50 to 200 mg every day (FDA approved)

- Paroxetine: starting dose: 10 mg every day; may be increased in 10 mg increments at intervals <sup>3</sup>1 week (FDA approved)
- Fluoxetine: 20 mg every day/BID not to exceed 80 mg/day (demonstrates some efficacy for all three symptom clusters)
- Sleep disruption: Sleep disruption due to hyperarousal is ubiquitous in PTSD. Standard sedatives, such as trazodone 50 to 300 mg at bedtime, mirtazapine 7.5 to 30 mg qhs, or amitriptyline 25 to 100 mg qhs
- Nightmares/nighttime hyperarousal: prazosin 2 to 15 mg qhs (7)[A], clonidine 0.1 to 0.2 mg qhs, amitriptyline 25 to 100 mg qhs

## Second Line

Refractory/residual symptoms: Consider augmentation with:

- Depression: mirtazapine 15 to 45 mg/day; consider switch to a serotonin-norepinephrine reuptake inhibitor (SNRI), such as venlafaxine XR 37.5 to 300 mg/day, duloxetine 60 to 120 mg/day, or desvenlafaxine 50 to 100 mg/day. Nefazodone 300 to 600 mg/day in divided doses can be very effective, but requires quarterly LFTs.
- Reexperiencing/intrusive thoughts: first-/second-generation antipsychotic medications: aripiprazole 5 to 15 mg/day, risperidone 0.5 to 2 mg/day, olanzapine 2.5 to 10 mg/day, quetiapine 50 to 400 mg/day (8)[A]. Second-generation Rx less prone to extrapyramidal symptoms (EPS): cognitive dulling
- Hyperarousal: clonidine, start 0.05 mg BID/TID; slowly titrate to as much as 0.45 mg/day divided doses; guanfacine 1 to 3 mg/day in divided doses (long-acting forms of both clonidine and guanfacine now available). Also consider second-generation antipsychotics quetiapine, risperidone, and olanzapine as above. Divided doses often more helpful.
- Impulsivity/explosiveness: anticonvulsants: valproic acid 500 to 2,000 mg/day, carbamazepine 200 to 600 mg/day, topiramate 50 to 200 mg/day
- Anxiety: benzodiazepines (see **ALERT**), including clonazepam, 1 to 4 mg/day in divided doses for a limited duration. Consider also hydroxyzine 25 to 50 mg TID/QID PRN or risperidone 0.25 to 0.5 mg TID PRN

### **ALERT**

Given risk of substance abuse and questionable benefit in PTSD, recommended benzodiazepines be avoided (9)[A]. Short-acting benzodiazepines presents the greatest risk.

## ADDITIONAL THERAPIES

- Psychotherapeutic interventions:
  - Exposure therapies have shown the highest effectiveness for treatment of PTSD (10)[A]:
    - Behavioral and cognitive-behavioral therapy (CBT): Early CBT has been shown to speed recovery. CBT is currently considered the standard of care for PTSD by the U.S. Department of Defense.
    - 1-week intensive CBT was as effective as 3-month weekly CBT in one study (11)[A].
    - Internet-based CBT has shown benefit in reduction of PTSD symptoms.
    - Prolonged exposure therapy: Reexperience distressing trauma-related memories and reminders to facilitate habituation and successful emotional processing of memory.
    - EMDR (eye movement desensitization and reprocessing) has been shown to benefit patients with PTSD (12)[A].
  - Stress-reduction techniques:
    - Immediate symptom reduction (e.g., rebreathing in a bag for hyperventilation)
    - Early recognition and removal from a stress
    - Relaxation, meditation, and exercise techniques are also helpful in reducing the reaction to stressful events.
  - Telemedicine-based collaborative care (with nurse case manager, pharmacy, psychology, and psychiatry) is more effective than usual care (13)[A].
- Interpersonal psychotherapy:
  - Supportive psychotherapy with an emphasis on the here and now
- Social:
  - Establish the social framework of the problem. Clarifying this allows the patient to begin viewing it within the proper context (e.g., change of job/relocation of adult-dependent offspring)

## ***INPATIENT CONSIDERATIONS***

Inpatient care is necessary only if the patient becomes suicidal/homicidal or for treatment of comorbid conditions (e.g., depression, substance abuse).

**ONGOING CARE**

# PATIENT EDUCATION

National Center for PTSD: [www.ptsd.va.gov](http://www.ptsd.va.gov)

## PROGNOSIS

- Varies significantly from patient to patient
- In 50% of cases, the symptoms spontaneously remit after 3 months; however, in other cases, symptoms may persist, often for many years, and cause longterm impairment in life functioning.
- Factors associated with a good prognosis include:
  - Rapid engagement of treatment
  - Early and ongoing social support
  - Avoidance of retraumatization
  - Positive premorbid function
  - Absence of other psychiatric disorders/substance abuse

## COMPLICATIONS

- Increased risk for panic disorder, agoraphobia, obsessive-compulsive disorder, social phobia, specific phobia, major depressive disorder, somatization disorder; impulsive behavior, suicide, and homicide. Victims of sexual assault are at especially high risk for developing mental health problems and committing suicide.
- Benzodiazepines lead to abuse and dependence.
- Avoidance of stimuli associated with the trauma can generalize to wide-ranging avoidance. This leads to a far greater negative impact on the patient's life.

American Psychiatric Association. *Diagnostic and Statistical Manual of Mental Disorders (DSM-V)*. 5th ed. Washington, DC: American Psychiatric Publishing; 2013.

## Codes

**&NA;**

### ICD10

- F43.10 Post-traumatic stress disorder, unspecified
- F43.11 Post-traumatic stress disorder, acute
- F43.12 Post-traumatic stress disorder, chronic

## Clinical Pearls

**&NA;**

- Treatment is often best accomplished with a combination of psychotherapy and pharmacotherapy.
- The sooner therapy is initiated after the trauma, the better the prognosis.

# Preeclampsia and Eclampsia (Toxemia of Pregnancy)

Konstantinos E. Deligiannidis, MD, MPH, FAAFP

## BASICS

### DESCRIPTION

- Preeclampsia is a disorder of pregnancy developing at the 20th week (or beyond), with new-onset hypertension (HTN) and new-onset proteinuria and/or impaired organ function:
  - May progress from mild to life-threatening in hours to days
  - The disorder is reversible by delivery if at term or, if maternal/fetal health are in danger, by preterm delivery.
  - Eclampsia is defined as new-onset grand mal seizure activity in a patient with preeclampsia without underlying neurologic disease.
  - Most postpartum cases occur within 48 hours of delivery but can occur up to 4 weeks postpartum.
- System(s) affected: cardiovascular, renal, reproductive, fetoplacental, CNS, hepatic
- Synonym(s): toxemia of pregnancy

### EPIDEMIOLOGY

#### Incidence

- Predominant age
  - Most cases occur in younger women because of the higher incidence of preeclampsia in younger (primiparous) women.
  - However, older (>40 years) patients with preeclampsia have 4 times the incidence of seizures compared with patients in their 20s.
- Preeclampsia: 5-8%
- Eclampsia develops in 1.6 to 10/10,000 deliveries in developed countries. In developing countries, estimates range from 6 to 157/10,000.

- 40% of eclamptic seizures occur before delivery; 16% occur >48 hours after delivery.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Systemic derangements in eclampsia include the following:

- Cardiovascular: generalized vasospasm
- Hematologic: decreased plasma volume, increased blood viscosity, hemoconcentration, coagulopathy
- Renal: decreased glomerular filtration rate
- Hepatic: periportal necrosis, hepatocellular damage, subcapsular hematoma
- CNS: cerebral vasospasm and ischemia, cerebral edema, cerebral hemorrhage

### *Genetics*

2 to 4 times increased risk in pregnant women with family history of preeclampsia

## *RISK FACTORS*

Nulliparity; age >40 years; family history of preeclampsia; high body mass index; diabetes; chronic HTN, chronic renal disease, or both; multifetal pregnancy; previous preeclampsia; systemic lupus erythematosus; in vitro fertilization (1)

## *GENERAL PREVENTION*

- Adequate prenatal care: Women who do not receive prenatal care are seven times more likely to die from complications.
- Good control of preexisting HTN
- Recent systematic reviews, meta-analyses, and task force recommendations show that low-dose aspirin (60 to 80 mg) started early in pregnancy may lower the risk of developing preeclampsia and the rate of preterm delivery and neonatal death in moderate to high-risk patients and has no significant effect on the rate of placental abruption/neonatal bleeding complications. The number needed to treat (NNT) to prevent one case of preeclampsia ranges from 18 to 118 depending on risk population, but more info is required to see which women would benefit and when to start therapy (1)[C],(2,3,4)[A]. It may be recommended in those with preeclampsia in >1 prior pregnancy or with a history of preeclampsia and preterm delivery (1)[C].
- Low-dose calcium supplementation has been shown to reduce the risk and severity of preeclampsia (relative risk [RR] = 0.38) in calcium-deficient populations (1)[C],(5)[A].
- Although some evidence suggests vitamin C (1,000 mg/day) and vitamin E (400 U/day) may

reduce the risk for preeclampsia, recent guidelines recommend against their use (1)[C],(6).

## COMMONLY ASSOCIATED CONDITIONS

Abruptio placentae, placental insufficiency, fetal growth restriction, preterm delivery, fetal demise, maternal seizures (eclampsia), maternal pulmonary edema, maternal liver/kidney failure, maternal death

## DIAGNOSIS

Diagnosis depends on new-onset elevated BP (SBP  $\geq$ 140 mm Hg or DBP  $\geq$ 90 mm Hg on two occasions at least 4 hours apart, or  $\geq$ 160/110 mm Hg) after 20 weeks of gestation AND EITHER proteinuria ( $>$ 300 mg/24 hr or spot protein:creatinine  $\geq$ 0.3), OR new-onset thrombocytopenia, renal insufficiency, impaired liver function, pulmonary edema, or cerebral/visual symptoms (1)[C]. This 2013 ACOG guideline suggests defining preeclampsia as either without or with severe features. Older guidelines use the term "mild" and "severe." The term "mild" is discouraged because preeclampsia is an evolving process that must be frequently evaluated for severity (1) [C].

## HISTORY

May be asymptomatic. In some cases, rapid excessive weight gain ( $>$ 5 lb/week;  $>$ 2.3 kg/week); more severe cases are associated with epigastric pain, headache, altered mental status, and visual disturbance.

## PHYSICAL EXAM

- BP criteria:
  - Preeclampsia without severe features: Elevated BP  $\geq$ 140/90 mm Hg on two occasions at least 4 hours apart, or more rapid diagnosis may be made with BP  $\geq$ 160/110 mm Hg.
  - Preeclampsia with severe features: Elevated BP  $\geq$ 160 systolic mm Hg or 110 mm Hg diastolic on two BP readings 4 hours apart while the patient is on bedrest, AND new onset of one or more of below:
    - Platelets  $<$ 100,000/ $\mu$ g/L
    - $>$ 2 times normal liver transaminase levels, severe persistent right upper quadrant (RUQ)/epigastric pain, or both
    - Creatinine  $>$ 1.1 mg/dL, or doubling of serum creatinine levels
    - Pulmonary edema
    - Cerebral or visual symptoms

- Eclampsia: tonic-clonic seizure activity (focal/generalized)
  - Note: headache, visual disturbance, and epigastric or RUQ pain often precede seizure
  - Seizures may occur once/repeatedly.
  - Postictal coma, cyanosis (variable)
  - Temperatures  $>39^{\circ}\text{C}$  may be consistent with CNS hemorrhage.
  - Normal BP, even in response to treatment; does not rule out potential for seizures

## *DIFFERENTIAL DIAGNOSIS*

- Chronic HTN: HTN before pregnancy; high BP before the 20th week
- Chronic HTN with superimposed preeclampsia
- Gestational HTN: Increased BP first discovered after 20 weeks, often close to term, with no proteinuria and without evidence of organ dysfunction. BP becomes normal by 12 weeks postpartum, or it is reclassified as chronic hypertension.
- Seizures in pregnancy: epilepsy, cerebral tumors, meningitis/encephalitis, ruptured cerebral aneurysm. Until other causes are proven, however, all pregnant women with convulsions should be considered to have eclampsia.

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Routine spot urine testing for protein should be done at each prenatal visit in all hypertensive patients
- CBC, including platelets, creatinine, serum transaminase levels, and uric acid as baseline in hypertensive patients and if preeclampsia suspected or possible
- Coagulation profiles: abnormalities suggest severe disease.
- 24-hour urine or protein/creatinine ratio if urine protein dips 1+ on more than one occasion, or if preeclampsia is being considered
- Daily fetal movement monitoring by mother (kick counts)
- US imaging is used to monitor growth and cord blood flow; perform, as indicated, based on clinical stability and laboratory findings.
- Nonstress test (NST) at diagnosis and then twice-weekly until delivery
- Biophysical profile if NST is nonreactive (1)[C]

- US imaging for growth progress every 3 weeks, and amniotic fluid volume at least once weekly (1)[C]
- With seizures, CT scan and MRI should be considered if focal findings persist or uncharacteristic signs/symptoms are present.

### *Follow-Up Tests & Special Considerations*

Disseminated intravascular coagulation, thrombocytopenia, liver dysfunction, and renal failure can complicate preeclampsia associated with HELLP syndrome.

### *Test Interpretation*

CNS: cerebral edema, hyperemia, focal anemia, thrombosis, and hemorrhage. Cerebral lesions account for 40% of eclamptic deaths.

## **TREATMENT**

- Preeclampsia without severe features:
    - Outpatient care
    - Maternal: daily home BP monitoring; daily weights; weekly labs (complete blood count [CBC], creatinine, liver function test [LFT])
    - Fetal:
      - Patient-measured: daily kick counts
      - Medical provider-measured: (see imaging section above)
      - Delivery at 37 weeks
- 
- Preeclampsia with severe features:
    - Inpatient care if patient condition deteriorates (BP  $\geq$  160/110 mm Hg; severe headache; visual changes [scotoma or flashing lights]; impaired mentation; pulmonary edema; epigastric/RUQ pain; increasing LFTs; oliguria; thrombocytopenia) or if fetal status is deemed nonreassuring
    - Maternal: daily labs, adding coagulation tests; IV magnesium sulfate as seizure prophylaxis; IV labetalol or hydralazine and oral sustained-release nifedipine antihypertensive therapy titrated to keep systolic BP < 160 mm Hg and diastolic BP < 110 mm Hg (some recommend < 150/100 mm Hg postpartum). Keep diastolic BP > 90 mm Hg to avoid hypoperfusing the uterus.

- Fetal: continuous heart monitoring; daily US with BP, amniotic fluid levels, fetal growth assessment as deemed necessary

## GENERAL MEASURES

Management by gestational age of severe preeclampsia:

- <23 weeks: Offer to terminate pregnancy.
- At 23 to 34 weeks: Antihypertensives; evaluate maternal-fetal condition; steroids to enhance fetal lung maturity; plan delivery at 34 weeks with magnesium sulfate prophylaxis.
- If severe HTN, eclampsia, DIC, pulmonary edema, abnormal fetal test results/evaluation, or abruption placentae, then plan delivery once maternal condition is stable.
- If HELLP syndrome (full or partial), severe oligohydramnios, significant renal dysfunction, persistent symptoms, fetal growth restriction, <sup>33</sup> 5/7 weeks' gestation, labor, or PROM, then steroids and then delivery after 48 hours.
- If the above do not apply, then expectant management until 34 weeks.
- At <sup>34</sup> weeks: magnesium sulfate and delivery (1)[C]

### ALERT

- Regardless of gestational age, emergent delivery is recommended if there are signs of maternal hypertensive crisis, abruptio placentae, uterine rupture, or fetal distress.
- Seizures: control of convulsions, correction of hypoxia and acidosis, lowering of BP, steps to effect delivery as soon as convulsions are controlled
- Administer betamethasone 12 mg IM daily × 2 doses or dexamethasone 6 mg every 12 hours × 4 doses if delivery <34 weeks possible.

## MEDICATION

### First Line

- For seizure prophylaxis for women with severe preeclampsia: magnesium sulfate (MgSO<sub>4</sub>): loading dose 4 g IV in 200 mL normal saline over 20 to 30 minutes; maintenance dose 1 to 2 g/hr IV continuous infusion (although recent guidelines suggest it not be universally administered for seizure prophylaxis to prevent eclampsia, the quality of the evidence is low, and the strength of the recommendation is qualified) (1)[C]
- For BP control
  - Antihypertensives are inadvisable for mildly elevated BP (without severe features).

- Labetalol (IV): 20 mg over 2 minutes followed at 20 to 30 minutes intervals with doses of 20 to 80 mg titrated to keep BP <160/110 mm Hg; max of 300 mg/24 hr. (Contraindicated in asthma, heart disease, congestive heart failure.)
- Hydralazine (IV): 5 to 10 mg over 2 minutes, followed at 20 minutes intervals with 5 to 10 mg IV boluses; titrated to keep BP<160/110 mm Hg; max of 25 mg/24 hr.
- Nifedipine sustained-release (PO) (used in the postpartum): 30 to 120 mg/day (caution with combination of nifedipine and magnesium sulfate resulting in hypotension and neuromuscular blockade)
- For eclampsia/seizures
  - In recent randomized trials, magnesium sulfate was found to be superior to phenytoin in the treatment and prevention of eclampsia and probably more effective and safer than diazepam.
  - Magnesium sulfate for seizures
    - 4 to 6 g IV over 15 to 20 minutes followed by 1 to 2 g/hr infusion
    - Further boluses of magnesium may be given for recurrent convulsions with the amount given based on the neurologic examination and patellar reflexes.
    - Contraindications: myasthenia gravis, renal failure, pulmonary edema
  - Levels of 6 to 8 mEq/mL are considered therapeutic, but clinical status is most important and must ensure that
    - Patellar reflexes are present.
    - Respirations are not depressed.
    - Urine output is  $\geq$ 25 mL/hr.
  - May be given safely, even in the presence of renal insufficiency
- Fluid therapy
  - Ringer lactated solution with 5% dextrose at 60 to 120 mL/hr, with careful attention to fluid-volume status
- Precautions: Do not use diuretics. Carefully monitor neurologic status, urine output, respirations, and fetal status.
- Calcium carbonate (1 g, administered slowly IV) may reverse magnesium-induced respiratory depression.

## *Second Line*

- Diazepam 2 mg/min until resolution or 20 mg given or
- Lorazepam 1 to 2 mg/min up to total of 10 mg or
- Phenytoin 15 to 20 mg/kg at a maximum rate of 50 mg/min or
- Levetiracetam 500 mg IV or oral, may be repeated in 12 hours (dose needs to be adjusted in renal impairment) or
- Phenobarbital 20 mg/kg infused at 50 mg/min; may repeat with additional 5 to 10 mg/kg after 15 minutes

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Without severe features: restricted activity; with severe features: restricted activity, in hospital
- Women with a history of preeclampsia should report this to physicians caring for them in later life. It is a potent cardiovascular disease risk factor.

### *DIET*

- Salt restriction is inadvisable because the patient often is experiencing intravascular hypovolemia (1)[C].
- Calcium supplementation may be recommended for women who have low calcium intake (<600 mg/day) (1,6)[A].

### *PATIENT EDUCATION*

American College of Obstetricians and Gynecologists, 409 12th St. SW, Washington, DC 20024-2188; (800) 762-ACOG; <http://www.acog.org/>

### *PROGNOSIS*

- For nulliparous women with preeclampsia before 30 weeks of gestation, the recurrence rate for the disorder may be as high as 40% in future pregnancies.
- 25% of eclamptic women will have HTN during subsequent pregnancies, but only 5% of these will be severe and only 2% will be eclamptic again.
- Preeclamptic, multiparous women may be at higher risk for subsequent essential HTN; they also have higher mortality during subsequent pregnancies than do primiparous women.

## COMPLICATIONS

- Most women do not have long-term sequelae from eclampsia, although many may have transient neurologic deficits.
- A history of preeclampsia is equivalent to traditional risk factors for cardiovascular disease. Women with a history of preeclampsia should be strongly advised to avoid obesity and smoking. Other signs of metabolic syndrome should be closely monitored as well.
- Maternal and/or fetal death

**Codes**

**&NA;**

## ICD10

- O14.90 Unspecified pre-eclampsia, unspecified trimester
- O15.00 Eclampsia in pregnancy, unspecified trimester
- O14.00 Mild to moderate pre-eclampsia, unspecified trimester

## Clinical Pearls

**&NA;**

- Management of preeclampsia depends on both the severity of the condition and the gestational age of the fetus.
- Diagnosis no longer requires presence of proteinuria.

# Premenstrual Syndrome (PMS) and Premenstrual Dysphoric Disorder (PMDD)

Courtney I. Jarvis, PharmD

Allison Hargreaves, MD

## BASICS

### DESCRIPTION

- Premenstrual syndrome (PMS), a complex of physical and emotional symptoms sufficiently severe to interfere with everyday life, occurs cyclically during the luteal phase of menses.
- Premenstrual dysphoric disorder (PMDD) is a severe form of PMS characterized by severe recurrent depressive and anxiety symptoms, with premenstrual (luteal phase) onset, that remits a few days after the start of menses.
- PMDD is now included as a full diagnostic category in the 5th edition of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-5)*.
- System(s) affected: endocrine/metabolic, nervous, reproductive

### EPIDEMIOLOGY

#### Prevalence

- Many women have some physical and psychological symptoms before menses (this is not PMS).
- 30% of menstruating women suffer from PMS; 3-8% of menstruating women have PMDD.

### ETIOLOGY AND PATHOPHYSIOLOGY

Not well understood. Leading theories postulate metabolites of progesterone interact with central neurotransmitter receptors (serotonin and  $\gamma$ -aminobutyric acid [GABA]), provoking downstream effects of decreased GABA-mediated inhibition and decreased serotonin levels. Women with PMS/PMDD have similar levels of progesterone but seem to have an increased sensitivity to its metabolites, compared with women without PMS/PMDD.

#### Genetics

Role of genetic predisposition is controversial; however, twin studies do suggest a genetic component.

- Involvement of gene coding for the serotonergic *5HT1A* receptor and allelic variants of the estrogen receptor- $\alpha$  gene (*ESR1*) is suggested.

## RISK FACTORS

- Age: usually present in late 20s to mid-30s
- History of mood disorder (major depression, bipolar disorder), anxiety disorder, personality disorder, or substance abuse
- Family history
- Low parity
- Tobacco use
- Psychosocial stressors/history of trauma
- High BMI

## DIAGNOSIS

### HISTORY

- *DSM-5* criteria (1)[A]
- Symptoms occur 1 week before menses, improve in the first few days after menses begin, and are minimal/absent in the week following menses (over most menstrual cycles during the past year).
- 5 of the following (1 must be among the first 4):
  - Marked depressed mood, feelings of hopelessness, or self-deprecating thoughts
  - Marked anxiety, tension, and/or feelings of being keyed up or on edge
  - Marked affective lability (mood swings)
  - Marked irritability or anger or increased interpersonal conflicts
  - Decreased interest in usual activities and social withdrawal
  - Lethargy, easy fatigability, or lack of energy
  - Appetite change, overeating, food cravings
  - Hypersomnia or insomnia
  - Feeling out of control or overwhelmed

- Subjective difficulty concentrating
- Physical symptoms, such as abdominal bloating, breast tenderness, headaches, weight gain, and joint/muscle pain
- For PMDD, emotional symptoms must be sufficiently severe to interfere with work, school, usual social activities, or relationships with others.
- Symptoms may be superimposed on an underlying psychiatric disorder but may not be an exacerbation of another condition, such as panic disorder/major depression.
- Criteria should be confirmed by prospective patient record of symptoms for a minimum of two consecutive menstrual cycles (without confirmation, “provisional” should be noted with diagnosis).
- Use the Daily Record of Severity of Problems (available online at <http://www.aafp.org/afp/2011/1015/p918-fig1.pdf>) or similar inventory (2) [A].
- Symptoms should not be attributable to drug abuse, medications, or other medical conditions.

## *PHYSICAL EXAM*

No specific physical exam required; may consider thyroid and pelvic exams if indicated by additional patient symptoms.

## *DIFFERENTIAL DIAGNOSIS*

- Premenstrual exacerbation of underlying psychiatric disorder
- Psychiatric disorders (especially bipolar disorder, major depression, anxiety)
- Thyroid disorders
- Perimenopause
- Premenstrual migraine
- Chronic fatigue syndrome
- Irritable bowel syndrome (painful symptoms)
- Seizures
- Anemia
- Endometriosis (painful symptoms)
- Drug/alcohol abuse

## DIAGNOSTIC TESTS & INTERPRETATION

- The repetitive nature of symptoms precludes need for labs if a classic history is present.
- Consider
  - Hemoglobin to rule out anemia
  - 25-OH vitamin D level to exclude deficiency, although precise relationship of deficiency with the disorder is unclear
  - Serum thyroid-stimulating hormone (TSH) to rule out hypothyroidism
- Imaging with pelvic ultrasound to diagnose causes of pelvic pain and dysmenorrhea may be needed.

## TREATMENT

### GENERAL MEASURES

Although evidence is lacking for aerobic exercise in treating PMS/PMDD, it is often recommended as part of an integrated care plan.

### MEDICATION

#### *First Line*

- SSRIs show a small to moderate effect in the treatment of physical, functional, and behavioral symptoms of PMS and PMDD compared to placebo (3)[A]:
  - Both intermittent luteal phase dosing and continuous full-cycle dosing are effective with no clear evidence of difference between modes of administration (3)[A].
  - All SSRIs tested appeared effective (3)[A].
  - SSRIs are effective at low doses. Higher doses have increased effect but are accompanied by increased side effects (3)[A].
- Fluoxetine (Prozac, Sarafem) 20 mg/day every day or 20 mg/day only during luteal phase, or 90 mg once a week for 2 weeks in luteal phase
- Sertraline (Zoloft) 50 to 150 mg/day every day or 50 to 150 mg/day only during luteal phase
- Citalopram (Celexa) 10 to 30 mg/day every day or 10 to 30 mg/day only during luteal phase
- Adverse effects (number needed to harm [NNH] with moderate-dose SSRI): nausea (NNH = 7), asthenia (NNH = 9), somnolence (NNH = 13), fatigue (NNH = 14), decreased libido (NNH = 14)

= 14), and sweating (NNH = 14) (3)[A].

- Contraindications: patients taking monoamine oxidase inhibitors (MAOIs)
- Precautions
  - Increased risk of suicidal thinking and behavior in children and adolescents with depressive disorders; uncertain if this risk applies to those taking SSRIs for PMDD
  - Bipolar disorder
  - Seizure disorder
  - QTc prolongation (with citalopram)
  - Hepatic dysfunction
  - Renal dysfunction
- Possible interactions
  - MAOIs
  - Selegiline
  - Pimozide
  - Thioridazine
  - Cimetidine, omeprazole, and QTc prolonging agents (with citalopram)

## *Second Line*

Alternative therapies should be considered if no response to SSRIs:

- Spironolactone (Aldactone) 50 to 100 mg/day for 7 to 10 days during luteal phase; helpful for fluid retention. Adverse reactions: lethargy, headache, irregular menses, hyperkalemia

---

P.841

- Oral contraceptive pills (OCPs)
  - OCPs can cause adverse effects similar to PMDD symptoms (4)[B].
  - Extended-cycle use of OCPs (e.g., 12 weeks on and 1 week off) or a shorter placebo interval (e.g., 24 active pills with 4 placebo days [24/4] compared with 21/7 preparations) may be beneficial (4)[B].
  - OCPs containing the progestin drospirenone (structurally similar to spironolactone) may improve physical symptoms and mood changes associated with PMDD (5)[A]. Caution: Risk of venous thromboembolism may be modestly higher than with other OCPs (4)[B].
  - Continuous administration of levonorgestrel/ethinyl estradiol may improve patient symptoms

in PMDD (4)[B].

- Suggested OCP formulations:
  - Ethinyl estradiol 0.02 to 0.03 mg/drospirenone 3 mg (Gianvi/Loryna/Nikki/Ocella/Syeda/Vestura/Yasmin/Yaz Zarah): 1 tablet/day
  - Ethinyl estradiol 0.02 to 0.03 mg/drospirenone 3 mg/levomefolate 0.451 mg (Beyaz/Safyral): 1 tablet/day
  - Levonorgestrel 90 &mgr;g/ethinyl estradiol 20 &mgr;g (Amethyst/Lybrel): 1 tablet/day
- Anxiolytics
  - Alprazolam (Xanax) 0.25 mg TID-QID only during luteal phase; taper at onset of menses (other benzodiazepines not studied for PMDD). Caution: addictive potential
  - Buspirone (BuSpar) 10 to 30 mg/day divided BID-TID in the luteal phase
- Ovulation inhibitors
  - Gonadotropin-releasing hormone (GnRH) agonists: leuprolide (Lupron) depot 3.75 mg/month IM
    - Precautions: Menopause-like side effects (e.g., osteoporosis, hot flashes, headaches, muscle aches, vaginal dryness, irritability) limit treatment to 6 months; may be first step if considering bilateral oophorectomy for severe, refractory PMDD
  - Danazol (Danocrine) 300 to 400 mg BID; adverse reactions: androgenic and antiestrogenic effects (e.g., amenorrhea, weight gain, acne, fluid retention, hirsutism, hot flashes, vaginal dryness, emotional lability)
  - Estrogen, transdermal preferred, 100 to 200 &mgr;g:
    - Precautions: increased risk of blood clot, stroke, heart attack, and breast cancer
    - Requires concomitant progesterone add-back therapy to protect against uterine hyperplasia and endometrial cancer
- Progesterone: insufficient evidence to support use (6)[A]

## ISSUES FOR REFERRAL

Referral to psychiatrist may be indicated for mood/anxiety disorders if patient has no symptom-free period.

## ADDITIONAL THERAPIES

Cognitive-behavioral therapy (CBT) is theoretically helpful for PMS/PMDD given its application for symptom reduction in other mood disorders, but direct evidence is lacking.

## ***SURGERY/OTHER PROCEDURES***

Bilateral oophorectomy, usually with concomitant hysterectomy, is an option for rare, refractory cases with severe, disabling symptoms.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Acupuncture demonstrated superiority to progestins, anxiolytics, and sham acupuncture with no evidence of harm (7)[A].
- Some data support the use of the following (8)[A]:
  - Calcium: 600 mg BID
  - Vitamin B<sub>6</sub>: 50 to 100 mg/day
  - Chasteberry (*Vitex agnus-castus*): 4 mg/day of extract containing 6% of agnuside (or 20 to 40 mg/day of fruit extract)
  - Omega-3 fatty acids 2 g/day
- Data insufficient regarding the following (8)[A]:
  - Magnesium: 200 to 400 mg/day
  - Vitamin D: 2,000 IU/day
  - Vitamin E: 400 IU/day
  - Manganese: 1.8 mg/day
  - St. John's wort: 900 mg/day
  - Soy: 68 mg/day isoflavones
  - Ginkgo: 160 to 320 mg/day
  - Saffron: 30 mg/day
- Evidence supporting efficacy and/or safety of herbal products is lacking; the following products/interventions have *not* been found useful for PMS/PMDD, although not all studies are of high quality and able to eliminate possibility of benefit completely (8)[A]:
  - Evening primrose oil
  - Black currant oil
  - Black cohosh

- Wild yam root
- Dong quai
- Kava kava
- Light-based therapy

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

Increased risk of suicidal thinking and behavior in children and adolescents with depressive disorders on initiation of SSRIs; uncertain if this risk applies to those taking SSRIs for PMDD

#### *DIET*

- Reduce consumption of salt, sugar, caffeine, dairy products, and alcohol (anecdotal reports).
- Eat small, frequent portions of food high in complex carbohydrates (limited data).

### *PATIENT EDUCATION*

- Counsel patients to eat a balanced diet rich in calcium, vitamin D, and omega-3 fatty acids and low in saturated fat and caffeine.
- Counsel women that they are not "crazy." PMDD is a real disorder with a physiologic basis.
- Although incompletely understood, successful treatment is often possible.

### *PROGNOSIS*

- Many patients can have their symptoms adequately controlled. PMS disappears at menopause.
- PMS can continue after hysterectomy, if ovaries are left in place.

## Codes

**&NA;**

## ICD10

## Clinical Pearls

### **&NA;**

- Have the patient keep a daily log of her symptoms and menses. Symptoms beginning in the week before menses and abating before the end of menses, occurring over at least 2 months, and sufficiently severe to interfere with daily functioning are diagnostic of PMS.
- The difference between PMS and PMDD is that PMDD is a severe form of PMS characterized by recurrent depressive and anxiety symptoms with luteal phase onset, sufficiently severe to disrupt social and occupational functioning. These symptoms remit a few days after the onset of menses.
- PMDD is not the same as more generalized depressive/anxiety disorders. PMDD-associated symptoms of depression and anxiety begin to resolve within the first few days of menses.
- Treatment only during the luteal phase is likely as effective as continuous-cycle treatment with SSRIs but has fewer adverse effects.

# Prenatal Care and Testing

Fozia Akhtar Ali, MD

Teny Anna Philip, MD

## BASICS

- The goal of prenatal care is to ensure the birth of a healthy baby with minimal risk for the mother by the following:
  - Identifying the patient who is at risk for complications
  - Estimating the gestational age (GA) as accurately as possible
  - Evaluating the health status of mother and fetus
  - Encouraging and empowering the patient to do her part to care for herself and her baby-to-be
  - Intervening when fetal abnormalities are present to prevent morbidity

## GENERAL PREVENTION

- A recommended prenatal care schedule consists of the following:
  - Monthly visits to a health care professional for weeks 4 to 28 of pregnancy
  - Visits twice monthly from 28 to 36 weeks
  - Weekly after week 36 (delivery at week 38 to 40)
- Recommendations for use of dietary supplements in pregnancy
  - Folic acid supplementation (0.4 to 0.8 mg) prior to conception; 4 mg for secondary prevention
  - Calcium: 1,000 to 1,300 mg/day; supplement may be beneficial for women with high risk for gestational hypertension or communities with low dietary calcium intake.
  - Iron: Screen for anemia (Hgb/Hct) and treat if necessary. Recommend 30 mg/day of iron in pregnant women.
  - Vitamin A: Pregnant women in industrialized countries should limit to <5,000 IU/day.
  - Vitamin D: Consider supplementation in women with limited exposure to sunlight.

- Routine thyroid screening and vitamin D deficiency during pregnancy is not recommended.

## DIAGNOSIS

### HISTORY

At the initial visit, a complete medical, obstetrical, family, and psychosocial history should be obtained and updated throughout the pregnancy.

- Assess and counsel as appropriate regarding the following:
  - Lifestyle, nutrition, safety of medications (teratogenicity, category); tobacco, alcohol, and drug use; toxins; relationship issues/domestic violence; stressors/supports; work environment; risk factors
- Domestic violence
  - ACOG guidelines recommend that physicians screen *all* pregnant patients for intimate partner domestic violence.
    - At the first prenatal visit
    - At least once per trimester
    - At the postpartum checkup

### PHYSICAL EXAM

- A full physical exam should be performed at the first prenatal appointment.
- At each subsequent prenatal visit, the following should be recorded:
  - Weight: Total weight gain range (lb) should be 25 to 35 lb, except in obese women, for whom weight gain should be <15 lb.
  - BP
    - ACOG defines hypertension as BP >140 mm Hg systolic or >90 mm Hg diastolic (1,2).
    - Monitor BP especially closely in patients with chronic hypertension (predating pregnancy), preeclampsia/eclampsia, or gestational hypertension.
  - UA for glucose and protein; 24-hour protein excretion is the gold standard but not practical.
  - Fundal height
  - Fetal heart rate: usually audible by 12 weeks' GA with a Doppler instrument
  - Routine fetal movement counts *not* recommended
  - Fetal position by abdominal palpation at 36 weeks

- Pelvic/cervical exam if indicated

## *DIAGNOSTIC TESTS & INTERPRETATION*

### **Cervical cancer screening**

- A Pap smear should be obtained when indicated by standard Pap screening guidelines, regardless of gestation (ACOG, USPSTF, ASCCP, ACS, and ASCP guidelines state that women <21 years should not be screened regardless of age of sexual initiation or other risk factors).
- Squamous intraepithelial lesions can progress during pregnancy but often regress postpartum.
- LSIL in pregnancy: colposcopy preferred, but it is acceptable to defer colposcopy to postpartum (3).
- Colposcopy only to exclude the presence of invasive cancer in high-risk women
- Cervical biopsy should be avoided unless a malignancy is suspected. Endocervical sampling is contraindicated.
- First prenatal visit
  - Lab tests
    - Hematocrit or hemoglobin
    - Blood type: A, B, AB, or O
    - Rhesus type and antibody screen: Rh(+) or Rh(-)
    - Hemoglobin electrophoresis for patients at risk for sickle cell disease or thalassemia
    - Urine testing for glucose and protein
    - Urine culture
    - Rubella titer
    - Syphilis test
    - Gonorrhea/chlamydia screening
    - Hepatitis B surface antigen
    - HIV testing (patient may opt out if chooses to decline)
    - Routine screening for bacterial vaginosis, toxoplasmosis, CMV, and parvovirus not recommended
    - Cystic fibrosis screening (information should be made available to all couples)

Cystic fibrosis carrier screening should be offered before conception or early in pregnancy when one partner is of Caucasian, European, or Ashkenazi Jewish descent (4).

- It is reasonable to offer cystic fibrosis carrier screening to all couples regardless of race or ethnicity as an alternative to selective testing.
- Screening tests (for birth defects), noninvasive
  - US nuchal translucency (NT): measures thickness at the back of the neck of the fetus
  - Blood screens: human chorionic gonadotropin (hCG), pregnancy-associated plasma protein A (PAPP-A), quad screen:  $\alpha$ -fetoprotein (AFP), unconjugated estriol (UE3), hCG, inhibin-A (INH-A)
  - Cell-free DNA testing should be offered as an alternative noninvasive method of screening for fetal aneuploidies to high-risk pregnant women between 10 and 22 weeks' gestation. Women who elect cell-free DNA testing will also need an AFP test for neural tube defects. The assay also allows screening for aneuploidy, rhesus typing in Rh(D) -negative women, and single-gene disorders (limited to detection of paternally inherited mutation). Because of a small but real risk for false-positive results, most experts advise using these assays as screening tests and confirming positive result with invasive prenatal diagnostics.
  - 1st-trimester screening between 11 and 14 weeks' GA using both NT and hCG/PAPP-A blood testing is an effective protocol in the general population and is more effective than NT alone, with an 83% detection rate for Down syndrome, with false-positive rate of 5%. Detects trisomy 21 (Down syndrome) and trisomy 18 (Edward syndrome). May be performed either as a single combined stand-alone test (US NT 1 blood [HCG and PAPP-A]) or as part of a sequential "step-by-step" 1st- and 2nd-trimester screening process (see the following discussion)
  - 2nd-trimester screening protocols
    - Obtain "multiple marker"/quad screen between 15 and 21 weeks' GA, optimally between 16 and 18 weeks;  $\approx$ 84% detection rate for trisomy 21, trisomy 18, and neural tube defects (NTDs), with false-positive rate of 5%, *or*
    - 2-step integrated screening protocol: combines information collected during the 1st and 2nd trimesters of the pregnancy to determine the risk of Down syndrome, trisomy 18, or open NTD:
      - Two options: stepwise sequential integrated screen ( $\approx$ 91% detection rate with false-positive rate 3.3%):
        - 1st trimester: NT measurement, plus blood (hCG, PAPP-A):

- If calculated risk for Down syndrome is  $\geq 1:30$ , then additional steps are recommended (genetic counseling, US, and chorionic villi sampling [CVS]).
  - If calculated risk for Down syndrome is  $< 1:30$  then
    - 2nd-trimester quad screen (AFP, UE3, hCG, INH-A) is required, or
    - Serum integrated screen: 88% detection rate with false-positive rate of 4.5%; requires a 1st-trimester PAPP-A blood test without NT measurement, and a 2nd-trimester (16- to 18-week quad screen)
  - Diagnostic tests (for birth defects), invasive
    - ACOG guidelines: All pregnant women, not just women  $\geq 35$  years, should be offered invasive prenatal diagnostic testing, such as CVS and amniocentesis to detect possible genetic abnormalities in their fetuses (5)[C].
    - Women found to be at increased risk of having a baby with Down syndrome with 1st-trimester screening should be offered genetic counseling and the option of CVS or midtrimester amniocentesis. If screening tests show increased risk of birth defect, there are two possible diagnostic tests:
      - CVS: 1st trimester: usually done after 10 weeks (10 to 12 weeks). Small sample of the placenta; chorionic tissue sample obtained either transcervical (TC) or transabdominal (TA). Complication: pregnancy loss rate of 1.0-1.5%
      - Amniocentesis
        - 1st trimester: usually at 11 to 13 weeks but higher rate of pregnancy loss and complication than either CVS or early 2nd-trimester procedures; therefore, not recommended
- 
- 2nd trimester: usually done after 15 weeks (15 to 18 weeks). The prenatal diagnostic technique associated with the lowest risk of pregnancy loss. Small sample of amniotic fluid from the amniotic sac surrounding the developing fetus is obtained by an US-guided TA approach. Complication: pregnancy loss rate of  $\approx 0.5\%$
- 24 to 28 weeks
    - Obtain diabetes screen (see the following discussion), repeat hematocrit or hemoglobin, and repeat antibody screen in Rh-negative mother prior to receiving prophylactic Rh immunoglobulin.
      - Gestational diabetes mellitus (GDM) screening: universal recommendation for ideal approach for screening and diagnosis of GDM remains elusive. In 2010, the International

Association of Diabetes and Pregnancy Study Group proposed a new system in which diabetes in pregnancy is classified as overt versus gestational diabetes. The American Diabetes Association reaffirmed this in 2010 and 2013. Presently, this system is not endorsed by ACOG because there is no evidence that one-step screening using this criteria leads to clinically significant improvements in maternal and fetal outcomes but would lead to significant increase in health care costs.

- Overt diabetes (test when women first present for prenatal care): fasting blood sugar  $\geq 126$  mg/dL or HbA1c  $\geq 6.5\%$ , or random  $\geq 200$  mg/dL that is confirmed with subsequent fasting blood sugar or HbA1c. (These thresholds were chosen due to correlation with adverse vascular events, e.g., retinopathy and CAD.)
- Gestational diabetes: fasting plasma glucose  $>92$  mg/dL but is  $<126$  mg/dL at any GA. At 24 to 28 weeks of gestation, a 75 g 2-hour oral glucose tolerance test with at least 1 abnormal result: FBG  $\geq 92$  mg/dL, but  $<126$  mg/dL or 1-hour  $\geq 180$  mg/dL, or 2-hour  $\geq 153$  mg/dL
- The prevalence of gestational diabetes in the United States can be 2-25%, greater in African Americans, Hispanics, Native Americans, and Asians than in Caucasians. Using the IADPSG criteria for overt versus gestational diabetes,  $\approx 18\%$  of women would be diagnosed with diabetes during pregnancy.
- The following guidelines for GDM are established by ACOG:
  - Specified cutoffs define GDM
    - A value of  $>130$  mg/dL will identify 90% of women with GDM, but 20-25% of all women screened will need to continue to the 3-hour oral glucose tolerance test (OGTT) (1,2).
    - Raising the value to  $>140$  mg/dL will identify only 80% of women with GDM but decrease to 14-18% the number of women who will need to continue to the 3-hour OGTT (6).
  - Screening test: 1-hour OGTT (nonfasting)
    - 50 g PO glucose load with blood glucose testing 1 hour later
    - Carpenter and Coustan positive screen:  $>130$  mg/dL
    - National Diabetes Data Group (NDDG) positive screen:  $>140$  mg/dL
  - Diagnostic test: 3-hour OGTT (fasting)
    - If abnormal 1-hour OGTT screening test, may be followed by a 3-hour OGTT
    - 100 g PO glucose load with blood drawn: fasting, 1, 2, and 3 hours after ingestion of glucose

- Either the plasma or serum glucose level designated by Carpenter and Coustan or by the NDDG are appropriate to use:
  - \* A positive diagnosis of GDM requires that <sup>3</sup>2 thresholds be exceeded.
    - Carpenter and Coustan standard
      - \* >95 (fasting), >180 (1-hour), >155 (2-hour), >140 (3-hour)
    - National Diabetes Data Group standard:
      - \*105 (fasting), >190 (1-hour), >165 (2-hour), >145 (3-hour)
- 35 to 37 weeks
  - Group B Streptococcus (GBS) culture: Universal screening for GBS colonization at 35 to 37 weeks of gestation remains the sole strategy for intrapartum antibiotic prophylaxis.
  - High-risk patients: High-risk patients should be screened again for gonorrhea, chlamydia, HIV, and syphilis.
- Postterm pregnancy
  - Rate of stillbirth increases with GA by 1/3,000 per week at 37 weeks; 3/3,000 per week at 42 weeks; and 6/3,000 at 43 weeks. In one meta-analysis, routine induction of labor at 41 weeks' gestation reduced rates of perinatal death without increased rates of cesarean delivery.
  - For gestational periods beyond 42 weeks, fetal well-being should be assessed with nonstress testing and US assessment of amniotic fluid volume.

## TREATMENT

### ISSUES FOR REFERRAL

Abnormal screening labs or imaging may prompt referral to maternal-fetal medicine specialist or other medical specialist, as indicated.

## ONGOING CARE

### PATIENT EDUCATION

Immunizations during pregnancy. The following vaccines are considered safe per CDC (7):

- Women should get (Tdap) during each pregnancy. Ideally, the vaccine should be given between 27 and 36 weeks of pregnancy. Hep B, and influenza; possibly include meningococcal, rabies. Contraindicated during pregnancy or safety not established: live vaccines including BCG, MMR, and varicella.
- Patients should be made aware of the tests that are performed routinely, as well as other tests that might be elected (e.g., CVS or amniocentesis), as well as the choices that would be available if testing were abnormal (pregnancy termination, preparation for the birth of an infant with congenital anomalies, further testing).
- Prevention
  - Preconception counseling offers the opportunity to discuss individualized risks.
- To decrease the risks of NTDs, preconception folate supplementation is indicated.
- Recommendations
  - Airline travel: generally safe until up to 4 weeks from EDD. Lengthy trips associated with increased risk of thrombosis
  - Caffeine: Limit to <200 mg/day. Correlation between IUGR and miscarriage with caffeine is undetermined at this time.
  - Exercise: Healthy women with uncomplicated pregnancies should continue to exercise.
  - Seat belts/air bags: ACOG recommends that pregnant women wear lap and shoulder seatbelts and should not turn off air bags.
  - Sexual activity: Intercourse is not associated with adverse outcomes.
- Alcohol, cigarettes, and illicit drugs are injurious to fetal and maternal health.
  - Pregnancy-safe medications (teratogenicity)

## Codes

**&NA;**

### ICD10

- Z34.90 Encntr for suprvsn of normal pregnancy, unsp, unsp trimester
- Z36 Encounter for antenatal screening of mother
- Z34.00 Encntr for suprvsn of normal first pregnancy, unsp trimester

## Clinical Pearls

**&NA;**

Prenatal care and screening are best accomplished using standardized flow sheets and checklists to ensure that the complex sequence of evaluations and education is performed consistently and properly.

# Preoperative Evaluation of the Noncardiac Surgical Patient

Andrew Grimes, MD

Stacy Jones, MD

## BASICS

### DESCRIPTION

- Preoperative medical evaluation should determine the presence of established or unrecognized disease or other factors that may increase the risk of perioperative morbidity and mortality in patients undergoing surgery.
- Specific assessment goals include the following:
  - Conducting a thorough medical history and physical exam to assess the need for further testing and/or consultation
  - Recommending strategies to reduce risk and optimize patient condition prior to surgery
  - Encouraging patients to optimize their health for possible improvement of both perioperative and long-term outcomes
- Synonym(s): preoperative diagnostic workup; preoperative preparation; preoperative general health assessment

### EPIDEMIOLOGY

Overall patient morbidity and mortality related to surgery is low. One large study of inpatients looking at 30-day mortality in the United States showed a rate of 1.32%. This rate varies by type of procedure and varies by country. Preoperative patient evaluation and subsequent optimization of perioperative care can reduce both postoperative morbidity and mortality.

### RISK FACTORS

- Functional capacity (1): Exercise tolerance is one of the most important determinants of cardiac risk:
  - Self-reported exercise tolerance may be an extremely useful predictive tool when assessing risk. Patients unable to meet a 4 metabolic equivalent (MET) demand (defined in the

Diagnosis section) during daily activities have increased perioperative cardiac and long-term risks.

- Patients who report good exercise tolerance require minimal, if any, additional testing.
- Levels of surgical risk
  - An increased risk for major adverse cardiac events (MACE) is associated with procedures that are intrathoracic, intra-abdominal, or vascular procedures that are suprainguinal in nature (1).
- Clinical risk factors (1): history of ischemic heart disease, the presence of compensated heart failure or a history of prior congestive heart failure (CHF), cerebrovascular disease, diabetes mellitus (DM), and renal insufficiency; these risk factors plus surgical risk can dictate the need for further cardiac testing.
- Age: Patients >70 years of age are at higher risk for perioperative complications and mortality and have a longer length of stay in the hospital postoperatively. (likely attributed to increasing medical comorbidities with increasing age) Age alone should not be a deciding factor in the decision to proceed or not proceed with surgery.

## DIAGNOSIS

### HISTORY

- Evaluate pertinent medical records and interview the patient. Many institutions provide standard patient questionnaires that screen for preoperative risk factors:
  - History of present illness and treatments
  - Past medical and surgical history
  - Patient and family anesthetic history and associated complications
  - Current medications (including over-the-counter [OTC] medications, vitamins, supplements, and herbals) as well as reasons for use
  - Allergies (including specific reactions)
  - Social history: tobacco, alcohol, drug use, and cessation
  - Family history: prior illnesses and surgeries
- Systems (both history and current status)
  - Cardiovascular: Inquire about exercise capacity.
    - 1 MET: can take care of self, eat, dress, and use toilet; walk around house indoors; walk a block or 2 on level ground at 2 to 3 mph

- 4 METs: can climb flight of stairs or walk uphill, walk on level ground at 4 mph, run a short distance, do heavy work around house, participate in moderate recreational activities
- 10 METs: can participate in strenuous sports such as swimming, singles tennis, football, basketball, or skiing
- Note presence of CHF, cardiomyopathy, ischemic heart disease (stable vs. unstable), valvular disease, hypertension (HTN), arrhythmias, murmurs, pericarditis, history of pacemaker or implantable cardioverter defibrillator (ICD):
  - Rhythm management devices (pacemakers and automatic ICDs [AICD]) affect the perioperative course. Most importantly, the following information need to be available for proper management: name of cardiologist who manages the device, type of device, manufacturer, last interrogation, and any problems that have occurred recently. Based on this information and the location and type of surgery, a perioperative plan of management will be made (2).
  - Stents: Patients with coronary stents are maintained on antiplatelet therapy with a thienopyridine, such as clopidogrel, frequently in combination with aspirin. Premature discontinuation of antiplatelet therapy markedly increases the risk of acute stent thrombosis, the results of which can be catastrophic. Elective surgery should be delayed and antiplatelet therapy continued for 4 to 6 weeks after bare-metal stent placement and for at least 12 months after placement of drug-eluting stents. Even after this time period, any perioperative disruption in the patient's antiplatelet regimen should be discussed with the patient's cardiologist and surgeon. The risk of perioperative bleeding must be weighed against the risks associated with discontinuation of antiplatelet drugs prior to surgery.
- Pulmonary: Chronic and active disease processes should be addressed: chronic infections, bronchitis, emphysema, asthma, wheezing, shortness of breath, cough (productive or otherwise):
  - Sleep apnea: Patients with obstructive sleep apnea (OSA) are at increased risk for perioperative adverse events. Because of the high incidence of undiagnosed sleep apnea in perioperative patients, many authors are recommending screening questionnaires such as the Berlin or STOP-BANG (3,4). The American Society of Anesthesiologists (ASA) has practice guidelines based on expert review that take into account the severity of sleep apnea, the invasiveness of surgery, and the projected

need for postoperative opioids (5).

- Patients with OSA frequently are at increased risk for obesity, coronary disease, HTN, atrial fibrillation, CHF, and pulmonary HTN. Optimizing the management of these comorbidities may be the first important step in the preoperative management of patients with OSA. Often, patients with an existing diagnosis of OSA who use continuous positive airway pressure (CPAP) at night are asked to bring their CPAP machine to the hospital or surgery center when they are admitted for surgery.
- Some studies suggest that even short periods (3 weeks) of treatment with CPAP can improve some indices of ventilation and therefore may reduce postoperative morbidity.
- GI: hepatic disease, gastric ulcer, inflammatory bowel disease, hernias (especially hiatal), significant weight loss, nausea, vomiting, history of postoperative nausea and vomiting: Any symptoms consistent with gastroesophageal reflux disease (GERD) should be optimally treated.
- Hematologic: anemia, serious bleeding, clotting problems, blood transfusions, hereditary disorders
- Renal: kidney failure, dialysis, infections, stones, changes in bladder function
- Endocrine: nocturia, parathyroid, pituitary, adrenal disease, thyroid disease
  - Diabetes: Evidence that hyperglycemia in the perioperative period is associated with increased perioperative complications. Although recommendations vary, most experts recommend keeping perioperative blood glucose levels <180.
- Neurologic/psychiatric: seizures, stroke, paralysis, tremor, migraine headaches, nerve injury, multiple sclerosis, extremity numbness, psychiatric disorders (e.g., anxiety, depression)
- Musculoskeletal: arthritis, lower back pain
- Reproductive: possibility of pregnancy in women of childbearing potential
- Mouth/upper airway: dentures, crowns, partials, bridges, teeth (loose, chipped, cracked, capped)

## *PHYSICAL EXAM*

- Assess vital signs, including arterial BP bilaterally.
- Check carotid pulses; auscultate for bruits.
- Examine lungs by auscultating all lung fields and listening for rales, rhonchi, wheezes, or other

sounds indicating disease.

- Examine cardiovascular system by auscultating heart and noting any irregular rhythms or murmurs; precordial palpation.
- Palpate abdomen.
- Examine airway and mouth for ease of intubation, neck mobility, and size of tongue; note any lesions or dental deformities.
- If a regional anesthesia technique is being contemplated, perform a relevant, focused neurologic exam.

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Laboratory testing should not be obtained routinely prior to surgery unless indicated (6)[C]. Specific tests should be requested if the evaluator suspects findings from the clinical evaluation that may influence perioperative patient management.
- Labs performed within the past 4 months prior to evaluation are reliable unless the patient has had an interim change in clinical presentation or is taking medications that require monitoring of plasma level or effect.

---

P.845

- CBC (6)[C]
  - Hemoglobin: if a patient has symptoms of anemia or is undergoing a procedure with major blood loss; extremes of age; liver or kidney disease
  - WBC count: if symptoms suggest infection or myeloproliferative disorder or the patient is at risk for chemotherapy-induced leukopenia
  - Platelet count: if history of bleeding, myeloproliferative disorder, liver or renal disease, or the patient is at risk for chemotherapy-induced thrombocytopenia
- Serum chemistries (electrolytes, glucose, renal and liver function tests): should be obtained for extremes of age; in known renal insufficiency, CHF, liver dysfunction, or endocrine abnormalities; or the patient is on medications that alter electrolyte levels, such as diuretics
- PT/PTT: if history of a bleeding disorder, chronic liver disease, or malnutrition, or those with recent or chronic antibiotic or anticoagulant use
- Urinalysis: Routine urinalysis is not recommended preoperatively.
- Pregnancy test: controversial; should be *considered* for all female patients of childbearing age
- CXR is not generally indicated. It can be considered in patients with recent upper respiratory

tract infection and in those with suspected cardiac or pulmonary disease (because there is a likelihood for unanticipated findings), but these indications are not considered unequivocal.

## Diagnostic Procedures/Other

- ECG (1)[C]
  - Preoperative resting 12 lead ECG is reasonable for patients with known coronary disease, known peripheral vascular disease, significant arrhythmia, or known significant structural heart disease.
  - ECGs are not indicated for asymptomatic patients undergoing low-risk procedures.
- The AHA guidelines recommend using the Revised Cardiac Risk Index or the ACS NSQIP online risk calculator to make an estimate of risk of MACE in the perioperative period. If the risk of MACE is low (<1%), then proceed with surgery. If the risk is >1%, the functional capacity needs to be considered. For patients with a functional capacity of >4 METS, then proceed with surgery. If the functional capacity is <4 METs or unknown, consider pharmacologic stress testing if it will change management (1).
- PFTs: Definitive data regarding the efficacy of preoperative testing are lacking. The most important factor is preoperative optimization of patients with chronic obstructive pulmonary disease (COPD) or reactive airways disease with indicated use of antibiotics, bronchodilators, and inhaled corticosteroids. Spirometry can help guide therapy. Upper abdominal and thoracic surgery have a higher risk of postoperative pulmonary complications.

## TREATMENT

### MEDICATION

- Reducing cardiac risk
  - Elective surgery should be delayed or canceled if the patient has any of the following: unstable coronary syndromes (unstable or severe angina), recent myocardial infarction (MI) (<30 days), decompensated heart failure, significant arrhythmias, or severe valvular disease.
  - Active HF should be treated with diuretics, afterload reduction, and  $\beta$ -adrenergic blockers.
  - Perioperative  $\beta$ -blockade has been shown to reduce mortality and the incidence of perioperative MIs in high-risk patients. Studies conflict, however, in which patients need to be treated, the dosage and timing of treatment, and for what surgeries. *Patients chronically on  $\beta$ -blockers should have the medication continued in the perioperative period. When*

*β*-blockers are discontinued in the perioperative period, 30-day mortality increases. *β*-Blockers are reasonable for vascular surgery patients with at least one clinical risk factor. It is not recommended to start *β*-blockers on the day of surgery in *β*-blocker naïve patients (1).

- Perioperative statin use may have a protective effect on reducing cardiac complications. Currently, the American Heart Association (AHA) has a class I indication for perioperative statin therapy for patients already on statins prior to their surgery. There is also evidence that vascular surgery patients benefit from perioperative statins.
  - A recent review looked at prophylactic use of aspirin in the perioperative period and did not find a significant effect on perioperative mortality or risk for MI in patients undergoing noncardiac surgery and may be associated with an increased risk of perioperative bleeding. There were important exclusion criteria including patients with recent stent placement (7).
- Reducing pulmonary risk
    - Recommend cigarette cessation for at least 8 weeks prior to elective surgery.
    - Patients with asthma should not be wheezing and should have a peak flow of at least 80% of their predicted or personal-best value.
    - Treatment of COPD and asthma should focus on maximally reducing airflow obstruction and is identical to treatment of nonsurgical patients.
    - Lower respiratory tract infections (bacterial) should be treated with appropriate antibiotic therapy.

Algorithm: Preoperative Evaluation of the Noncardiac Surgical Patient

## Codes

**&NA;**

### ICD10

- Z01.818 Encounter for other preprocedural examination
- Z01.811 Encounter for preprocedural respiratory examination
- Z01.812 Encounter for preprocedural laboratory examination

## Clinical Pearls

**&NA;**

- The preoperative evaluation should include medical record evaluation, patient interview, and physical exam.
- The minimum for the physical exam includes airway, pulmonary, and cardiovascular exams.
- Functional capacity, the level of surgical risk, and clinical risk factors determine if further cardiac testing is needed.
- No preoperative tests are routine.
- Active cardiac conditions should lead to delay or cancellation of nonemergent surgery.

# Presbycusis

Matthew J. Richter, DO

John T. Ewing, DO

## BASICS

### DESCRIPTION

- Age-related, bilateral sensorineural hearing loss (SNHL) typically symmetric
- Represents a lifetime of insults to the auditory system from toxic noise exposure and natural decline
- Initially presents as high-frequency SNHL with tinnitus (ringing)
- Impacts the clarity of sounds (i.e., ability to detect, identify, and localize sounds)
- Due to mild and progressive nature, presbycusis is often treated with amplification alone.
- Can lead to adverse effects on physical, cognitive, emotional, behavioral, and social function in the elderly (e.g., depression, social isolation)

### EPIDEMIOLOGY

#### *Incidence*

According to an ongoing community-based epidemiologic study, the 10-year cumulative incidence rates of hearing loss (HL) are as follows (1):

- Age 48 to 59 years: M (31.7%), F (15.6%); all (21.8%)
- Age 60 to 69 years: M (56.8%), F (40.7%); all (45.5%)
- Age 70 to 79 years: M (87.1%), F (70.6%); all (73.7%)
- Age 80 to 92 years: M (100%), F (100%); all (100%)

#### *Prevalence*

- 10% of the population develops SNHL severe enough to impair communication.
- Increases to 40% in the population >65 years of age
- 80% of HL cases occur in elderly patients.

- Only 10-20% of older adults with HL have ever used hearing aids.
- Predominant sex: male > female
- Hearing levels are poorer in industrialized societies than in isolated or agrarian societies.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- The external ear transmits sound energy to the tympanic membrane. The middle ear ossicles amplify and conduct the sound waves into the inner ear (cochlea) via the oval window. The organ of Corti, located in the cochlea, contains hair cells that detect these vibrations and depolarize, producing electrical signals that travel through the auditory nerve to the brain. Toxic noise exposure traumatizes the hair cells and leads to cell death and hearing loss. New research also suggests that overexcitation of the neurosynapses causes increased glutamate, which is also neurotoxic (2).
  - Sensory presbycusis: primary loss of the hair cells in the basal end of the cochlea (high frequency HL)
  - Neural presbycusis: loss of spiral ganglion cells (nerve cells induced by hair cells to produce action potentials to travel to the brainstem)
  - Strial (metabolic) presbycusis: atrophy of the stria vascularis (the cochlear tissue that generates the endocochlear electrical potential)
  - Cochlear conductive (mechanical) presbycusis: no morphologic findings (presumed stiffening of the basilar membrane)
  - Mixed presbycusis: combinations of hair cell, ganglion cell, and stria vascularis loss
  - Indeterminate presbycusis: no morphologic findings (presumed impaired cellular function)
- Presbycusis is caused by the accumulated effects of noise exposure, systemic disease, oxidative damage, ototoxic drugs, and genetic susceptibility.

### *Genetics*

Presbycusis has a clear familial aggregation (3)[B]:

- Heritability estimates show 35-55% of the variance of sensory presbycusis is from genetic factors; even greater percentage in strial presbycusis
- Heritability is stronger among women than men.

## *RISK FACTORS*

- Noise exposure (military, industrial, etc.)

- Ototoxic substances
  - Organic solvents
  - Heavy metals
  - Carbon monoxide
- Drugs
  - Aminoglycosides
  - Cisplatin
  - Salicylates
  - Diuretics
- Tobacco smoking
- Alcohol
- Lower socioeconomic status
- Family history of presbycusis
- Head trauma (temporal bone fractures)
- Cardiovascular disease (hypertension, atherosclerosis, hyperlipidemia); labyrinthine artery is terminal artery to the cochlea.
- Diabetes mellitus
- Autoimmune disease (autocochleitis/labyrinthitis)
- Metabolic bone disease
- Endocrine medical conditions: levels of aldosterone
- Alzheimer disease
- Otologic conditions (e.g., Ménière disease or otosclerosis)

## **GENERAL PREVENTION**

- Avoid hazardous noise exposure.
- Use hearing protection.
- Maintain healthy diet and exercise.
- Screening
  - In the only published RCT on screening for HL, hearing aid use was significantly higher in

three screened groups (4.1% in those using a questionnaire, 6.3% using handheld audiometry, and 7.4% using both modalities) versus unscreened control participants (3.3%) at 1-year follow-up (4)[B].

- Based on a 2011 review, according to the USPSTF, there is insufficient evidence to assess the relative benefits and harms of HL screening in adults <sup>3</sup>50 years (5)[A].

## DIAGNOSIS

### HISTORY

- Reduced hearing sensitivity and speech understanding in noisy/public environments
- Impaired localization of sound sources
- Increased difficulty understanding conversations, especially with women, due to higher frequency of spoken voice
- Presents bilaterally and symmetrically
- If unilateral hearing loss, alternative diagnosis should be pursued.
- Additional history if HL is suspected or detected (6)[B]
  - Time course of HL
  - Symptoms of tinnitus, otalgia, otorrhea, or vertigo
  - History of noise exposure, ear trauma, or head trauma
  - Presence of any neurologic deficit
- Reports from patient/family/caregiver (6)[B]
  - Confusion in social situations
  - Excessive volume of television/radio/computer
  - Social withdrawal
  - Anxiety in group settings

### PHYSICAL EXAM

- Rinne and Weber tests are helpful for determining conductive versus sensorineural hearing loss but not recommended for general screening (7)[B].
- Pneumatic otoscopy to evaluate for simple middle ear effusion as cause of conductive hearing loss

### DIFFERENTIAL DIAGNOSIS

- Acute noise-induced traumatic loss (explosion)
- Autoimmune HL
- Perilymph fistula (trauma/iatrogenic)
- Ménière disease
- Acoustic neuroma
- Complete canal occlusion (cerumen)
- Otitis externa
- Chronic otitis media or effusion
- Otosclerosis/osteogenesis imperfecta
- Large middle ear tumors (e.g., facial nerve schwannomas, paragangliomas)
- Vascular anomaly
- Cholesteatoma

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Handheld audiometry; insert probe in ear (sealing canal) and have patient indicate if tones can be heard.
  - Positive likelihood ratio (LR) range, 3.1 to 5.8; negative LR range, 0.03 to 0.40 (7)[B]
- Screening audiometry
  - Symmetric high-frequency hearing loss in descending slope pattern
  - SNHL frequencies >2 KHz initially
  - Essential to determine global clinical hearing status and if etiology is conductive hearing loss versus SNHL or pseudohypacusis (conversion)

---

P.847

## **TREATMENT**

- Hearing aids (HAs)
  - Types
    - Analog HA: picks up sound waves through a microphone; converts them into electrical signals; amplifies and sends them through the ear canal to the tympanic membrane

- Digital HA: programmable; may reduce acoustic feedback, reduce background noise, detect and automatically accommodate different listening environments, control multiple microphones
- HAs have an average decibel gain of 16.3 dB
- Associated with hypersensitivity to loud sounds (Òloudness recruitmentÓ)
- Hearing-assistive technologies (HATs) (8)[A]
  - Can be used alone or in combination with HAs (for difficult listening conditions)
  - Addresses face-to-face communication, broadcast or other electronic media (radio, TV), telephone conversation, sensitivity to alerting signals and environment stimuli (doorbell, baby's cry, alarm clock, etc.)
  - Includes personal FM systems, infrared systems, induction loop systems, hardwired systems, telephone amplifier, telecoil, TDD (telecommunication device for the deaf), situation-specific devices (e.g., television), alerting devices
- Aural rehabilitation (also known as audiologic orientation or auditory training) (6)[A]
  - Adjunct to HA or HATs
  - Involves education regarding proper use of amplification devices, coaching on how to manage the auditory environment, training in speech perception and communication, and counseling for coping strategies to deal with the difficulties of HAs or HATs

## *ISSUES FOR REFERRAL*

Refer to audiologist for formal evaluation and optimal fitting of HAs and/or HATs.

- Individuals receiving postfitting orientation/education have significantly fewer HA returns.
- Individuals receiving >2 hours of education and counseling report higher levels of satisfaction.

## *SURGERY/OTHER PROCEDURES*

- Cochlear implants (CIs) (9,10)[B]
  - Indications include hearing no better than identifying <sup>2</sup>50% of key words in test sentences in the best aided condition in the worst ear and 60% in the better ear.
  - Works by bypassing the ear canal, middle ear, and hair cells in the cochlea to provide electric stimulation directly to the auditory nerve
  - Incoming sounds are received through the microphone in the audio processor component (resembles a small HA), which converts them into electrical impulses and sends them to the

magnetic coil (located on the skin). The impulses transmit these across intact skin via radio waves to the implanted component (directly subjacent to the coil). The pulses travel to the electrodes in the cochlea and stimulate the cochlea at high rates.

- Receiving a unilateral CI is most common; some may receive bilateral CIs (either sequentially or in the same surgery). Others may wear a CI in 1 ear and an HA in the contralateral ear (bimodal fit).
- Younger age at CI placement derives greatest benefit (10)[A].
- Active middle ear implants (AMEIs) (9)[B]
  - Suitable for elderly adults who cannot wear conventional HAs for medical or personal (cosmetic) reasons and whose HL is not severe enough for a CI
  - Comes in different models and may include components that are implantable under the skin
- Electric acoustic stimulation: use of CI and HA together in one ear
  - Addresses the specific needs of patients presenting with good low-frequency hearing (a mild to moderate sensorineural HL in frequencies up to 1,000 Hz) but poorer hearing in the high frequencies (sloping to 60 dB or worse HL above 1,000 Hz) (9)[B]
    - Contraindications: progressive HL, autoimmune disease; HL related to meningitis, otosclerosis, or ossification; malformation of the cochlea; a gap in air conduction and bone conduction thresholds of >15 dB; external ear contraindications, active infection, or unwillingness to use amplification devices (9)[B]

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- During follow-up visits, check for compliance of HA use.
  - 25-40% of adults will either stop wearing them or use them only occasionally.
- Assess perceived benefit of HA and, if ineffective, for indications for possible surgical treatments.
- Annual audiograms
- Can follow up with audiologists for HA fittings if HA becomes uncomfortable
- Asymmetric hearing loss should have evaluation via MRI for acoustic neuroma.

- Sudden SNHL is atypical and warrants urgent otolaryngologic evaluation/audiometry. The most recent recommendations by the American Academy of Otolaryngology recommend steroids empirically.

## PATIENT EDUCATION

- Should be face-to-face; spoken clearly and unhurriedly, without competing background noise (e.g., radio, TV); and include a confirmation that the message is received.
- Formal speech reading classes may be beneficial; however, availability may be limited.

## Codes

**&NA;**

### ICD10

- H91.10 Presbycusis, unspecified ear
- H91.13 Presbycusis, bilateral
- H91.11 Presbycusis, right ear

## Clinical Pearls

**&NA;**

- Presbycusis is an age-related hearing loss (HL), showing increased incidence with age. It is often bilateral and initially begins as high-frequency HL. It presents as difficulty communicating in noisy conditions.
- There are more affected males than females.
- Compliance is only from 25-40% for those who own hearing aids (HA). A referral to an audiologist is key for optimal evaluation, fitting for HAs, and other assistive technologies or surgical treatment.
- Indication for CIs include hearing no better than identifying 25% key words in test sentences in the best aided condition in the worst ear and 60% in the better ear.
- Early audiology referral for individuals with suspected HL may improve treatment efficacy.

# Pressure Ulcer

Amy M. Zack, MD, FAAFP

## BASICS

### DESCRIPTION

- A localized area of soft tissue injury resulting from pressure between an external surface and a bony prominence that causes local tissue breakdown classified in stages according to the National Pressure Ulcer Advisory Panel (NPUAP) classification.
  - Stage I: erythema of localized area, usually nonblanching over bony surface; may be painful, have consistency or temperature difference from surrounding tissue
  - Stage II: partial loss of dermal layer, resulting in pink ulceration; may be fluid-filled blister, or shiny, dry ulcer
  - Stage III: Full dermal loss often exposing subcutaneous tissue and fat.
  - Stage IV: Full-thickness ulceration exposing bone, tendon, or muscle. Osteomyelitis may be present.
- Synonym(s): decubitus ulcer; bed sores

### EPIDEMIOLOGY

#### *Incidence*

2.5 million pressure ulcers treated yearly in United States in acute care facilities (1)

#### *Prevalence*

- Acute care 0.4-38%; long-term care 2.2-23.9%; home care 0-17%
- Majority occur in patients >65 years: 36% with hip fracture, 50% in ICU care (2)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Pathophysiology of pressure ulcers is changing, differs depending on stage of ulceration.
- Stages I to II result largely from prolonged moisture and friction and may not even be related to pressure and hypoxia, as previously believed (3).

- Stages III to IV likely begin with compressive forces, causing muscle damage and tissue hypoxia and leading to reperfusion injury of the deep tissue. The skin ulcer forms after significant deep tissue damage is already under way (3).
- Shearing and friction forces are also components of some ulcer formation, resulting in localized skin damage and early-stage ulcers (3).

## **RISK FACTORS**

- Immobility: greatest risk factor regardless of patient, temporary or permanent immobility (4)
- Urinary and fecal incontinence present in >80% of immobile patients with pressure ulcers
- Poor nutritional status: Hypoalbuminemia and low BMI are markers for poor ulcer outcome (4).
- Poor skin perfusion, including vascular disease, diabetes, anemia, and tobacco use, increases risk.
- Extended stay in hospital/nursing home, inadequate staffing (5)
- Other risks include history of previous ulcer, age-related skin changes, immunocompromise, impaired skin sensation, and impaired awareness.
- Assessment scales commonly used for risk evaluation include Braden and Norton scales. The use of these does not decrease incidence, but they are more accurate than clinical judgment alone (6)[A].

## **GENERAL PREVENTION**

- *Up to 95% are preventable*; identification of at-risk patients within 8 hours of admission, with early multidisciplinary care
- *Skin assessment*: policy in all health care settings (5)[B]
  - Increase frequency of assessments with decline in clinical condition (5)[C].
  - Include erythema, edema, skin temperature, and consistency in all evaluation (5)[B].
  - Assess around medical devices twice daily (5)[C].
- *Pressure relief*
  - Establish pressure relief schedule.
  - Proper patient positioning and the use of mattresses, cushions, heel protectors, and other devices to minimize pressure and friction
  - Regular turning of patients, including the use of angles and rotation of extremities, helps to minimize pressure.

- *Avoid positioning on area of erythema* (5)[C].
- *Minimize duration of immobility*: adequate physical and occupational therapies when appropriate
- *Aggressive moisture prevention*: management plan for incontinence (5)[C]
- *Nutrition*
  - Complete assessment of nutritional status and form plan, particularly protein intake and albumin levels.
  - Reassess with all changes in condition.
  - Develop individualized nutritional care plan for protein, calories, vitamins, and hydration (5)[C].
- *Manage skin health*: clean and dry with mild cleansers, skin protection where appropriate. Avoid massage or rubbing skin prone to ulcers (5)[C].
- *Microclimate control*: emerging therapy, control moisture, and temperature when selecting support structure. Avoid use of heating devices (5)[C].
- *Prophylactic dressings*: emerging therapy, apply foam dressing to bony prominences to avoid friction and shear (5)[B].
- *Textiles and fabrics*: Sheets and clothing should be silk-like rather than cotton or other abrasives.

## COMMONLY ASSOCIATED CONDITIONS

See ÒRisk Factors.Ó

## DIAGNOSIS

### HISTORY

- Risk factors
- Date of ulcer diagnosis
- Treatment course

## PHYSICAL EXAM

- Do full skin examination on admission to hospital or extended-care facility and repeatedly throughout admission, best with bathing/bed changes.
- 83% of hospitalized patients with decubitus ulcers develop them in first 5 days of

hospitalization.

- Classify ulcer based on NPUAP stages (see Description).
- Focus on skin color, consistency, and temperature changes when classifying ulcer.
- Assess and document location, category, size, tissue, color, edges, sinus tracts, exudate, odor.
- Assess pain (5)[B].

## ***DIFFERENTIAL DIAGNOSIS***

- Venous stasis ulcers
- Arterial ulcers resulting from poor vascular supply
- Diabetic ulcers
- Pyoderma gangrenosum, cancers, vasculitides, and other dermatologic conditions

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Wound culture: Do not culture surface drainage. If culture necessary, do deep tissue culture/bone biopsy.
- If systemic infection or that of bone, muscle is suspected, add infectious workup, including inflammatory markers, CBC, blood cultures, x-ray. MRI may be necessary to confirm osteomyelitis.
- Nutritional assessment: BMI, protein and calorie intake, albumin, prealbumin, CBC for anemia. No clear evidence in support of specific nutritional supplements including zinc and vitamin C (7)[A],(8)[B].

### ***Follow-Up Tests & Special Considerations***

Additional tests may be indicated when additional medical illness complicates assessment. This may include testing for diabetes, vascular disease, and other dermatologic diagnoses.

## **TREATMENT**

### ***GENERAL MEASURES***

- Pressure reduction, minimize immobility, manage incontinence, and improve nutritional status

and skin health (as described in 'Prevention')

- Wound management by stage of ulcer
  - Stage I: aggressive preventive measures, thin film dressings for protection
  - Stage II: occlusive dressing to maintain healing, transparent films, hydrocolloids
  - Stages III to IV: debridement of necrotic tissue. Exudative ulcers will benefit from absorptive dressings such as calcium alginates, foams, hydrofibers. Dry ulcers require occlusive dressing to maintain moisture, including hydrocolloids, and hydrogels.

---

- Debridement: type depends on extent of necrosis or eschar, or presence of biofilm; incisional with scalpel when extensive dry. Mechanical with wet-dry dressings; enzymatic debridement is also frequently used. Debride only when there is adequate perfusion to wound.
- Surgical closure may be necessary in advanced wounds.
- Vacuum-assisted closure
  - Negative pressure reduces wound edema and improves local tissue perfusion.
  - Removes necrotic debris and reduces bacterial load
  - Literature review demonstrates the efficacy of negative-pressure wound therapy (9)[A].
- Dressings: mixed evidence for improvement (10)[B]
  - Select based on wound, exudate, ulcer stage.
  - Gauze: Avoid use, if no other options, wet-to-dry only.
  - Hydrocolloid: clean, shallow Stage II, not infected
  - Transparent: autolytic debridement, not for use on heavy exudate or over enzymatic debriding agents
  - Hydrogel: Stage II, shallow, minimal exudate, not infected
  - Alginate: Stage II to III, shallow with heavy exudate, infected, long duration dressing
  - Foam: Stage II to III, shallow with heavy exudate
  - Collagen-matrix: nonhealing Stage III to IV
  - Silver impregnated: infected or heavily colonized, high risk infection, short duration only
  - Honey impregnated: Stage II/III
  - Cadexomer iodine: Stage II/III with heavy exudate

P.849

# MEDICATION

## First Line

- See "General Measures" for first-line treatment.
- Pain control
- Aggressive management of contributing medical conditions
- Infection: If suspected, treat appropriately for cellulitis or osteomyelitis.
  - High index of suspicion for infection: poor healing, odor, pain, warmth, drainage, necrosis, diabetes, malnutrition, poor perfusion, immunosuppression, culture with  $>10^5$  cfu/g or GBS presence
- Topical therapy
  - DŽbride as indicated
  - Nontoxic topical anesthetics including iodine, silver sulfadiazine, chlorhexidine (avoid hydrogen peroxide, Dakin solution) (5)[C]

## Second Line

Nutritional interventions as determined by nutritional assessment. Weak evidence to support protein supplementation to reduce wound size (10)[C]

## ISSUES FOR REFERRAL

- Vascular surgery is a consideration for improvement of blood flow to wound via vascular bypass.
- Plastic surgery is a consideration for skin graft/flap.

## ADDITIONAL THERAPIES

- Alternative therapies
  - Light, laser, acoustic have little shown benefit.
  - Whirlpool contraindicated (5)[B]
  - Electrical stimulation shows some benefit (10)[B].

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Nutritional support as needed

- Ultrasound and electrical stimulation create new vasculature in affected region (9)[C].

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Refractory cellulitis, osteomyelitis, systemic infection, advanced nutritional decline, suspected patient mistreatment, inability to care for self

### *Nursing*

- Dressing changes 1 to 3 times daily based on wound assessment and plan of care
- Assess risk factors according to scales.
- Assess for new or changing wounds.

### *Discharge Criteria*

Clinical improvement in wound and systemic illness; when applicable, safe, and appropriate location for discharge

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Weekly assessment by nurse with wound experience; biweekly assessment by physician

### *Patient Monitoring*

- Home health nursing
- Change in plan of care if no improvement in 2 to 3 weeks

### *DIET*

- 1 to 1.5 kg/day of protein
- Good glycemic control
- Include supply of micronutrients in diet or as supplements.

### *PATIENT EDUCATION*

- Check skin regularly.
- Signs and symptoms of infection

- Report new or increased pain.
- Prevention of new wound where old wound healed
- Skin care, moisture prevention

## PROGNOSIS

Variable, depending on the following:

- Removal of pressure
- Nutrition
- Wound care

## COMPLICATIONS

- Infection
- Amputation

Stansby G, Avital L, Jones K, et al. Prevention and management of pressure ulcers in primary and secondary care: summary of NICE guidance. *BMJ.* 2014;348:g2592.

## Codes

**&NA;**

### ICD10

- L89.95 Pressure ulcer of unspecified site, unstageable
- L89.91 Pressure ulcer of unspecified site, stage 1
- L89.92 Pressure ulcer of unspecified site, stage 2

## Clinical Pearls

**&NA;**

- Create assessment and prevention protocols for all patients.
- Identify risk, reduce pressure, maximize nutrition, regular skin checks, and assess and treat

wound appropriately.

- All care needs to be done in time-sensitive, patient-centered fashion.

# Preterm Labor

Kara M. Coassolo, MD

John C. Smulian, MD, MPH

## BASICS

### DESCRIPTION

Contractions occurring between 20 and 36 weeks' gestation at a rate of 4 in 20 minutes or 8 in 1 hour with at least one of the following: cervical change over time or dilation  $\geq 2$  cm

### EPIDEMIOLOGY

Preterm birth is the leading cause of perinatal morbidity and mortality in the United States.

#### *Incidence*

10-15% of pregnancies experienced at least one episode of preterm labor.

#### *Prevalence*

$\approx$  12% of all births in the United States are preterm (9% spontaneous preterm births and 3% indicated preterm births).

### ETIOLOGY AND PATHOPHYSIOLOGY

- Premature formation and activation of myometrial gap junctions
- Inflammatory mediator-stimulated contractions
- Weakened cervix (structural defect or extracellular matrix defect)
- Abnormal placental implantation
- Systemic inflammation/infections (e.g., UTI, pyelonephritis, pneumonia, sepsis)
- Local inflammation/infections (intra-amniotic infections from aerobes, anaerobes, *Mycoplasma*, *Ureaplasma*)
- Uterine abnormalities (e.g., cervical insufficiency, leiomyomata, Müllerian anomalies, diethylstilbestrol exposure)
- Overdistension (by multiple gestation or polyhydramnios)

- Preterm premature rupture of membranes
- Trauma
- Placental abruption
- Immunopathology (e.g., antiphospholipid antibodies)
- Placental ischemic disease (preeclampsia and fetal growth restriction)

## *Genetics*

Familial predisposition

## ***RISK FACTORS***

- Demographic factors, including single parent, poverty, and black race
- Short interpregnancy interval
- No prenatal care
- Prepregnancy weight <45 kg (100 lb), body mass index <20
- Substance abuse (e.g., cocaine, tobacco)
- Prior preterm delivery (common)
- Previous 2nd-trimester dilation and evacuation (D&E)
- Cervical insufficiency or prior cervical surgery (cone biopsy or loop electrosurgical excision procedure [LEEP])
- Abdominal surgery/trauma during pregnancy
- Uterine structural abnormalities such as large fibroids or müllerian abnormalities
- Serious maternal infections/diseases
- Bacterial vaginosis
- Bacteriuria
- Vaginal bleeding during pregnancy
- Multiple gestation
- Select fetal abnormalities
- Intrauterine growth restriction
- Placenta previa
- Premature placental separation (abruption)

- Polyhydramnios
- Ehlers-Danlos syndrome

## GENERAL PREVENTION

- Patient education at each visit in 2nd and 3rd trimesters for those at risk and periodically in the last two trimesters for the general population
- If previous preterm birth, evaluate if etiology is likely to recur and target intervention to specific condition.
  - Weekly injections of 17 $\alpha$ -hydroxyprogesterone (250 mg IM every week) from 16 to 36 weeks if previous spontaneous preterm birth
  - Consider cerclage placement before 24 weeks' gestation for those at high risk because of cervical insufficiency or significant or progressive cervical shortening (1)[A],(2)[C].
  - For women with a short cervix in the 2nd trimester (<20 mm on transvaginal US), progesterone 200 mg/day per vagina for 24 to 34 weeks may decrease the risk of preterm delivery (3)[A].

## DIAGNOSIS

Diagnosis is generally based on a combination of significant cervical changes (such as dilation, effacement) with regular contractions. However, there is no single test that will reliably diagnose or predict true preterm labor. The diagnosis is based on a combination of physical findings and diagnostic tests that are interpreted in the context of the degree of risk to the patient.

### HISTORY

- Address risk factors, especially etiologies of previous preterm birth.
- Regular uterine contractions or cramping
- Dull, low backache or pain
- Intermittent lower abdominal pain
- Increased low pelvic pressure
- Change in vaginal discharge
- Vaginal bleeding
- Fluid leakage

## PHYSICAL EXAM

- Sterile speculum exam for membrane rupture evaluation, cultures, and cervical inspection

- Bimanual cervical exam if intact membranes: dilation of the cervix >1 cm and/or effacement of the cervix >50%

## **ALERT**

Avoid bimanual examination when possible if rupture of the membranes is suspected.

## ***DIFFERENTIAL DIAGNOSIS***

- Braxton-Hicks contractions/false labor
- Round ligament pain
- Lumbosacral muscular back pain
- Urinary tract or vaginal infections
- Adnexal torsion
- Degenerating fibroid
- Appendicitis
- Dehydration
- Viral gastroenteritis
- Nephrolithiasis

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- In symptomatic women from 22 to 34 weeks' gestation with intact membranes and no intercourse or bleeding in past 24 hours, obtain a fetal fibronectin (FFN) swab from the posterior vaginal fornix (4)[C]. FFN must be obtained prior to digital cervical exam.
  - If results are positive ( $^3$ 50 ng/mL), patient is at a modest increased risk of preterm birth (positive predictive value [PPV] 13-30% for delivery within 2 weeks).
  - If results are negative, >97% of patients will not deliver in 14 days, so can consider avoiding complicated or high-risk interventions.
- Urinalysis and urine culture
- Cultures for gonorrhea and chlamydia
- Wet prep for bacterial vaginosis evaluation (although evidence for improved outcomes with treatment is weak)

- Vaginal introitus and rectal culture for group B *Streptococcus*
- pH and ferning test of vaginal fluid to evaluate for rupture of membranes
- CBC with differential
- Drug screen when appropriate
- US to identify number of fetuses and fetal position, confirm gestational age, estimate fetal weight, quantify amniotic fluid, and look for conditions making tocolysis contraindicated.
- Transvaginal US to evaluate cervical length, funneling, and dynamic changes after obtaining FFN (if clinical assessment of the cervix is uncertain or if the cervix is closed on digital exam)

### *Follow-Up Tests & Special Considerations*

- Repeat FFN as indicated by symptoms.
- After successful treatment, progressive changes of the cervix on repeat examination or US (in 1 to 2 weeks) may indicate need for hospitalization.

### *Diagnostic Procedures/Other*

- Monitor contractions with external tocodynamometer.
- Consider amniocentesis at any preterm gestational age to evaluate for intra-amniotic infection (cell count with differential, glucose, Gram stain, aerobic, anaerobic, *Mycoplasma*, *Ureaplasma* cultures).

### *Test Interpretation*

- Placental inflammation
  - Acute inflammation usually caused by infection
  - Chronic inflammation caused by immunopathology
- Abruption

## **TREATMENT**

### *GENERAL MEASURES*

- Treat underlying risk factors (e.g., antibiotics for infections, hydration for dehydration).
- Liquids only or NPO if delivery is imminent

- Hospitalization is necessary if the patient is on IV tocolysis.

## MEDICATION

Tocolysis may allow time for interventions such as transfer to tertiary care facility and administration of corticosteroids but may not prolong pregnancy significantly (5)[A].

### First Line

- Tocolysis
  - Nifedipine: 30 mg PO loading dose; then 10 to 20 mg q6h for 24 hours; then 10 to 20 mg PO q8h (do not use sublingual route); check BP often and avoid hypotension. Concurrent use with magnesium sulfate should be avoided to avoid theoretic risk of neuromuscular blockade.
  - Indomethacin: 50 to 100 mg PO initial dose; then 25 to 50 mg q6-8h for 24 hours (or, if available, 100-mg suppository per rectum q12h for 2 doses); then 25 mg q6-8h; use for no longer than 72 hours due to risk of premature closure of ductus arteriosus, oligohydramnios, and possibly neonatal necrotizing enterocolitis. Use with caution in patients with platelet dysfunction, liver dysfunction, or allergy to aspirin.
  - Contraindications to tocolysis: severe preeclampsia, hemorrhage, chorioamnionitis, advanced labor, intrauterine growth retardation, fetal distress, or lethal fetal abnormalities
- Antibiotics: antibiotics for group B *Streptococcus* prophylaxis if culture is positive or unknown
- Steroids: If mother is at 23 to 34 weeks' gestation with no evidence of systemic infection, give glucocorticoids to decrease neonatal respiratory distress, intraventricular hemorrhage, necrotizing enterocolitis, and overall perinatal mortality. Betamethasone 12 mg IM for 2 doses 24 hours apart (preferred choice) *or* dexamethasone 6 mg IM q12h for 4 doses (6)[A]

### Second Line

- Magnesium sulfate by IV infusion has not been shown to be superior to placebo in prolonging pregnancy beyond 48 hours. The side effects are generally greater compared with calcium channel blockers or NSAIDs. Therefore, this agent should be used cautiously if at all (standard dosages for tocolysis start with a 4- to 6-g IV bolus over 20 minutes followed by 2 to 3 g/hr infusion until contractions stop) (7)[C].
  - Magnesium may decrease the risk of cerebral palsy when 12-hour course is given prior to an anticipated preterm birth.
  - Relative contraindications to magnesium sulfate include myasthenia gravis, hypocalcemia, renal failure, or concurrent use of calcium channel blockers.

- Terbutaline 0.25 mg SC q30min for up to 3 doses until contractions stop, then 0.25 mg SC q6h for 4 doses (optional); if contractions persist or pulse >120 bpm, change to another tocolytic agent (may be poorly tolerated by mothers).
- Terbutaline PO or by infusion pump has been used in the past for treatment or prevention of preterm labor. Due to reports of serious cardiovascular events and maternal deaths, PO or long-term SC administration of terbutaline should not be given.
- Significant possible interactions include pulmonary edema from crystalloid fluids and tocolytic agents, especially magnesium sulfate.
- PO maintenance therapy with any agent is ineffective and is not recommended.

## ***ISSUES FOR REFERRAL***

- If delivery is inevitable but not immediate, consider transport to a tertiary care center or hospital equipped with a neonatal ICU.
- Consider consultation with maternal-fetal medicine specialist.

## ***ADDITIONAL THERAPIES***

- Pelvic rest (e.g., no douching or intercourse) and activity restriction are often recommended; however, data to prove the efficacy are lacking. Some reduction in physical activity may be reasonable; this should be individualized.
- Strict bed rest has not been demonstrated to be effective in most situations.

## ***SURGERY/OTHER PROCEDURES***

- For malpresentation or fetal compromise, consider cesarean delivery if labor is progressing.
- Cerclage for cervical insufficiency (until 24 weeks' gestation)

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Suspected/threatened preterm labor

- IV access
- Continuous fetal and contraction monitoring
- Assess cervix for dilatation and effacement.

### ***IV Fluids***

Hydrate with 500 mL 5% dextrose normal saline solution or 5% dextrose lactated Ringer solution for first half hour; then at 125 mL/hr.

## *Nursing*

Monitor for fluid overload (input/output monitoring, symptoms, lung auscultation, pulse oximetry), especially with tocolysis and multiple gestations.

## *Discharge Criteria*

- Regular contractions and cervical change resolve
- If cervix is dilated  $\geq 3$  cm or FFN is positive, individualize decision to discharge by gestational age and patient circumstances.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- Weekly office visits with contraction monitoring, cervical checks, or cervical US if at high risk for recurrence
- Routine use of maintenance tocolysis is ineffective in preventing preterm birth.

## *DIET*

Regular

## *PATIENT EDUCATION*

Call physician or proceed to hospital whenever regular contractions last >1 hour, bleeding, increased vaginal discharge or fluid, decreased fetal movement.

## *PROGNOSIS*

- If membranes are ruptured and no infection is confirmed, delivery often occurs within 3 to 7 days.
- If membranes are intact, 20-50% deliver preterm.

## **COMPLICATIONS**

Labor resistant to tocolysis, pulmonary edema, infection with preterm rupture of membranes

## Codes

&NA;

## ICD10

- O60.00 Preterm labor without delivery, unspecified trimester
- O60.02 Preterm labor without delivery, second trimester
- O60.03 Preterm labor without delivery, third trimester

## Clinical Pearls

**&NA;**

- Treatment of preterm labor may delay delivery to facilitate short-term interventions.
- Steroids improve neonatal outcomes.
- Progesterone therapy can prevent recurrence of preterm birth in next pregnancy.

# Priapism

Shenelle Wilson, MD

Kelvin A. Moses, MD, PhD

## BASICS

### DESCRIPTION

- Penile erection that lasts for >4 hours and is unrelated to sexual stimulation or excitement.
- Classified into ischemic and nonischemic types
- Ischemic (low-flow) priapism is painful and requires urgent clinical intervention.
- Stuttering priapism is recurrent episodes of short-lived, self-limiting ischemic priapism over an extended period.
- Nonischemic (high-flow) priapism is painless, could be related to prior trauma, and does not require urgent treatment.
- Malignant priapism is a rare condition resulting most commonly from penile metastases from primary bladder, prostatic, rectosigmoid, and renal tumors.
- System(s) affected: reproductive

### *Pediatric Considerations*

In children, nearly all priapism is caused either by sickle cell anemia or trauma (1).

### EPIDEMIOLOGY

#### *Incidence*

In the United States, one study estimates 1,868 to 2,960 cases of priapism each year. They also noted an increasing incidence from 1998 to 2006, specifically in those from nonhematologic causes (2):

- Mean age: 33.7 years. There has been an age shift in recent years toward men in their 40s.
- Other studies have found the incidence of priapism to double in men aged >40 years (2.9 vs. 1.5/100,000 person-years) (3).
- Race: 61.1% black, 30% white, 6.3% Hispanic

- Associations: sickle cell anemia (41.9%), drug abuse (7.9%), sickle cell trait (2.5%)
- Anatomy and physiology
  - The penis consists of three longitudinally oriented corpora: two dorsolaterally paired corpora cavernosa that are responsible for penile erection and a single ventral corpus spongiosum that surrounds the glans penis and extends distally to form the glans penis
  - In general, the penile artery (which is a branch of the internal pudendal artery that, in turn, is a branch from the internal iliac artery) supplies the penis. It divides into three branches: dorsal artery, bulbar artery (supplies the corpus spongiosum), and cavernosal artery (the main blood supply to the erectile tissue).
  - During an erection, smooth muscle relaxation of the cavernosal arterioles results in high-volume inflow to the sinusoids, resulting in compression of the exiting venules. This leads to significant volume expansion of the corpora cavernosa.
  - During the flaccid resting state, the sympathetic nervous system is predominantly in control. Penile tumescence and erection are driven by the parasympathetic nervous system through the generation of nitric oxide (NO).
  - Smooth muscle relaxation occurs via usage of the phosphodiesterase type 5 (PDE-5A) pathway, which generates cyclic guanosine monophosphate (cGMP).

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- In ischemic priapism, decreased venous outflow results in increased intracavernosal pressure. This leads to erection, decreased arterial inflow, blood stasis, local hypoxia, and acidosis (a compartment syndrome). Eventually, penile tissue necrosis and fibrosis may occur. The exact mechanism is unknown and may involve trapping of erythrocytes in the veins, draining the erectile bodies.
- In nonischemic priapism, there is increased arterial flow without decreased venous outflow. There is increased inflow and outflow, which results in a sustained, nonpainful, partially rigid erection.
- Aberrations in the PDE-5A pathway have been proven in mice to be one mechanism of priapism (4).
- Ischemic priapism
  - Idiopathic, estimated to about 50% (1)
  - Intracavernosal injections of vasoactive drugs for erectile dysfunction
  - Oral agents for erectile dysfunction
  - Pelvic vascular thrombosis

- Prolonged sexual activity
- Sickle cell disease and trait
- Leukemia from infiltration of the corpora
- Other blood dyscrasias (G6PD deficiency, thrombophilia)
- Pelvic hematoma or neoplasia (penis, urethra, bladder, prostate, kidney, rectal)
- Cerebrospinal tumors
- Asplenism
- Fabry disease
- Tertiary syphilis
- Total parenteral nutrition, especially 20% lipid infusion (results in hyperviscosity)
- Bladder calculus
- Trauma to penis
- UTIs, especially prostatitis, urethritis, cystitis
- Several drugs suspected as causing priapism (e.g., chlorpromazine, prazosin, cocaine, trazodone, and some corticosteroids); anticoagulants (heparin and warfarin); phosphodiesterase inhibitors (sildenafil, others); immunosuppressants (tacrolimus); and antihypertensives (hydralazine, propranolol, guanethidine)
- Intracavernous fat emulsion
- Hyperosmolar IV contrast
- Spinal cord injury
- General or spinal anesthesia
- Heavy alcohol intake or cocaine use
- Nonischemic priapism
  - The most common cause is penile or perineal trauma resulting in a fistula between the cavernous artery and the corpora.
  - Acute spinal cord injury
  - Rarely, iatrogenic causes for the management of ischemic priapism can result in nonischemic priapism.
  - Certain urologic surgeries have also resulted in nonischemic priapism.

## *RISK FACTORS*

- Sickle cell anemia, lifetime risk of ischemic priapism 29-42% (1)
- Dehydration

## *GENERAL PREVENTION*

- Avoid dehydration.
- Avoid excessive sexual stimulation.
- Avoid causative drugs (see *Etiology and Pathophysiology*) when possible.
- Avoid genital and pelvic trauma.

## *COMMONLY ASSOCIATED CONDITIONS*

- Sickle cell anemia or sickle cell trait
- Drug abuse
- G6PD deficiency
- Leukemia
- Neoplasm

## **DIAGNOSIS**

### **HISTORY**

- Penile erection that is persistent, prolonged, painful, and tender (ischemic).
- Duration of erection, degree of pain
- Perineal or penile trauma
- Prior episodes of priapism
- Urination difficult during erection
- History of any hematologic abnormalities
- Cardiovascular disease
- Medications
- Recreational drugs
- Loss of erectile function if treatment is not prompt and effective.

## *PHYSICAL EXAM*

- Ischemic priapism
  - Penis is fully erect, corpora cavernosa are rigid and tender, and corpora spongiosum and glans are flaccid. Usually associated with tenderness and pain
- Nonischemic priapism
  - Penis is partially erect and the corpora cavernosa are semirigid and nontender, with the glans and corpora spongiosum flaccid. Usually not tender or painful
- Perineum, abdomen, and lymph node exam also valuable to rule out underlying condition.
- A complete penile and scrotal exam is necessary. Determine if a penile prosthesis is present.

## *DIAGNOSTIC TESTS & INTERPRETATION*

- CBC with reticulocyte count to detect leukemia or platelet abnormalities
- Sickling hemoglobin (Hgb) solubility test and Hgb electrophoresis
- Coagulation profile
- Platelet count
- Urinalysis
- Urine toxicology if illicit drugs suspected
- Corporal blood gas (CBG) should be used to distinguish ischemic from nonischemic priapism.
- A color duplex ultrasound of the penis and perineum may be necessary to differentiate ischemic from nonischemic priapism. In ischemic priapism, there is no blood flow in the cavernosal arteries, whereas in nonischemic patients, there is high blood flow (1); may also see fistulas or pseudoaneurysms suggestive of nonischemic priapism.
- Penile arteriography can be used to identify the presence and site of fistulas in patients with nonischemic priapism.

### *Diagnostic Procedures/Other*

A physical exam is usually able to distinguish ischemic from nonischemic priapism; however, CBG is the most definitive method.

### *Test Interpretation*

- Pelvic vascular thrombosis
- Partial thrombosis of corpora cavernosa of the penis
- Corpus spongiosum, glans penis: no involvement

- Arterial priapism will show arteriocavernous fistula.

## TREATMENT

- Ischemic priapism requires immediate treatment to preserve future erectile function (a longer delay in treatment means a higher chance of future impotence).
  - Cavernosal aspiration with a large bore needle with irrigation (success rate  $\div$ 30%) (1,5)
  - Cavernosal injection of phenylephrine ( $\alpha$ -adrenergic sympathomimetic) with monitoring of patient's BP and pulse (success rate  $\div$ 65%) (5). Inject q5-10min until detumescence.
  - Continue aspiration, irrigation, and phenylephrine for several hours. If this fails, shunt procedures are considered (first a distal shunt).
- Nonischemic priapism
  - Initial observation
  - If this fails, arteriography and embolization with absorbable materials (5% rate of impotence vs. 39% with permanent materials) or surgical ligation as a last resort (5)
- Treat the underlying condition (i.e., sickle cell disease). Do not delay intracavernous treatment.

## GENERAL MEASURES

- Reassure the patient about the outcome, if warranted.
- Provide continuous caudal or spinal anesthesia if the etiology is neurogenic.
- Treat any underlying cause.
- In sickle cell anemia: IV hydration; supplemental oxygen; partial exchange or repeated transfusions to reduce percentage of sickle cells to  $<$ 50%
- Relieve the patient's pain.
- Initiating proper management depends on whether the priapism is ischemic or nonischemic.

## MEDICATION

- Opioids for pain, if needed
- Intracavernous injection of phenylephrine is recommended by the American Urological Association for ischemic priapism (5).
- Phenylephrine minimizes risk of cardiovascular side effects that are more common with other

sympathomimetics; terbutaline has been studied and may be effective (uncontrolled trials showed a 65% resolution rate) for priapism caused by self-injection of agents to treat erectile dysfunction (5).

- Ketoconazole 200 mg TID and prednisone 5 mg daily for 2 weeks; then tapering to ketoconazole 200 mg nightly for 6 months has been shown to prevent recurrent ischemic priapism (6).
- For stuttering priapism, a trial of gonadotropin-releasing hormone (GnRH) agonists or antiandrogens is effective; self-injection of phenylephrine is also effective.
- PDE-5 inhibitors also have a role in the prevention of priapism in patients suffering from stuttering priapism (7).

## ISSUES FOR REFERRAL

A urologist should be consulted in all cases of suspected priapism to ensure the highest likelihood of preserved erectile function.

## SURGERY/OTHER PROCEDURES

- For ischemic priapism, introduction of 18- or 19-gauge needle into corpora cavernosa (best done by urologist if available) at 9 o'clock and 3 o'clock positions with aspiration of 20 to 30 mL of blood from corpus cavernosum. May follow with intracavernous injection of 100 to 500  $\mu$ g phenylephrine (mix 0.2 mL [200  $\mu$ g] of 1% phenylephrine in 9.8 mL of normal saline. 1 mL injections given every 3 to 5 min for  $\approx$ 1 hour before determining if treatment is successful. If this fails, consider shunts.
- Distal shunts
  - Percutaneous: Ebbehøj, Winter, or T-shunt (8,9,10)
  - Open: Al-Ghorab or corporal snake (11,12)
- Proximal shunts
  - Open: Quackles or Sacher (13,14)
  - Saphenous vein shunt (15)
  - Deep dorsal vein shunt (16)

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

Bed rest until priapism resolves

## *Patient Monitoring*

Close follow-up with a urologist is required after surgical treatments for priapism.

## **PATIENT EDUCATION**

- Information about long-term outlook, referral for counseling
- Reduction of vasoactive drug therapy if responsible for priapism, and elimination of offending drugs if causal

## **PROGNOSIS**

- Even with excellent treatment for a prolonged priapism, detumescence may require several weeks secondary to edema (1).
- Impotence due to irreversible corporal fibrosis is likely in ischemic priapism and is up to 90% if the priapism lasts >24 hours.
- Despite early intervention, ischemic priapism is likely to result in impotence in up to 50% of men.

## **COMPLICATIONS**

Erectile dysfunction (i.e., impotence)

**&NA;**

Anemia, Sickle Cell; Erectile Dysfunction

## Codes

**&NA;**

### ICD10

- N48.30 Priapism, unspecified
- N48.39 Other priapism
- N48.31 Priapism due to trauma

## Clinical Pearls

**&NA;**

- Priapism is a prolonged penile erection that lasts >4 hours and is unrelated to sexual stimulation.
- In evaluating priapism, the clinician must distinguish ischemic from nonischemic priapism by history and physical exam, as well as blood gas and possibly ultrasound, if needed.
- Ischemic priapism is an emergent condition that requires immediate urologic evaluation and treatment.
- The most common causes of ischemic priapism are idiopathic, related to treatments for erectile dysfunction, or related to use of substances (medicinal or recreational).
- If an underlying medical condition is identified (sickle cell anemia), proper concomitant

treatment is necessary to increase the efficacy of treatment.

# Prostate Cancer

Jason K. Frankel, MD

Gregory Murphy, MD

Joseph R. Wagner, MD

## BASICS

### DESCRIPTION

- The prostate is a male reproductive organ that contributes seminal fluid to the ejaculate.
- The prostate gland is about the size of a walnut, averaging 20 to 25 g in volume in an adult male; tends to enlarge after age 50
- Three distinct zones delineate the functional anatomy of the prostate: peripheral zone (largest, neighbors rectal wall, palpable on DRE, most common location for prostate cancer), central zone (contains the ejaculatory ducts), and transition zone (located centrally, adjacent to the urethra).
- Prostatic epithelial cells produce prostate specific antigen (PSA), which is used as a tumor marker and in screening.

### EPIDEMIOLOGY

#### *Incidence*

According to the National Cancer Institute, an estimated 220,800 men in the United States will be newly diagnosed with carcinoma of the prostate (CaP) in 2015.

#### *Prevalence*

- About 2.8 million men are living with CaP in the United States
- ÷27,540 men in the United States will die of CaP in 2015.
- Mean age at diagnosis is 66 years.
- Prostate cancer is the most commonly diagnosed nonskin cancer in men in the United States (÷15.9% lifetime risk) and second leading cause of cancer death in men (only ÷3% of all CaP results in CaP-related death).
- Autopsy studies find foci of latent CaP in 50% of men in their 8th decade of life.

- Probability of clinical CaP 10.9% (1 in 9) in men aged  $\geq 70$  years

## ETIOLOGY AND PATHOPHYSIOLOGY

- Adenocarcinoma: >95%; nonadenocarcinoma: <5% (most common transitional cell carcinoma)
- Cells generally stain positive for PSA and prostatic acid phosphatase (PAP)
- Location of CaP: 70% peripheral zone, 20% transitional zone, 5-10% central zone

### Genetics

Elevated risk if first-degree relative diagnosed with CaP suggesting genetic component. Specifics unclear

## RISK FACTORS

- Age >50 years
- African American race
- Positive family history
- Poorly understood environmental factors

## GENERAL PREVENTION

There are no FDA approved drugs or diet modifications to prevent CaP.

- Finasteride has been studied for this purpose. A moderate risk reduction associated with an increased risk of high-grade disease was encountered. Therefore, it has not been FDA approved for prevention (1)[A].

### **ALERT**

Screening for prostate cancer is controversial:

- U.S. Preventive Services Task Force (USPSTF) recommends against PSA-based screen for prostate cancer, concluding the harm of screening outweighs benefit (2)[A].
- For men ages 55 to 69 years, the AUA panel recommends shared decision making between physician and patient regarding PSA screening.
- PSA screening is not recommended in patients with <10 years of estimated life expectancy.

**DIAGNOSIS**

## HISTORY

- Inquire about family history of CaP, symptoms of bladder outlet obstruction, and other voiding symptoms.
- Anorexia and weight loss, bone pain (with metastasis), hematuria, hematospermia (rare)

## PHYSICAL EXAM

- DRE to assess for prostatic masses, firmness, or asymmetry
- Evaluate lumbar spine and lymph nodes for evidence of metastasis.

## ALERT

Most patients with CaP are asymptomatic.

## DIFFERENTIAL DIAGNOSIS

Benign prostatic hyperplasia, prostatitis, prostatic intraepithelial neoplasia (PIN), prostate stones, atypical small acinar proliferation (ASAP)

- The high predictive value of ASAP for subsequent adenocarcinoma warrants repeat biopsy within 3 months.

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

PSA, DRE, and clinical history primarily determine need for prostate biopsy:

- In general, total PSA  $\geq 4$  ng/mL concerning for CaP (sensitivity 21%, specificity 91%)
  - Other benign conditions can elevate PSA (infection, inflammation, normal growth, natural PSA fluctuations, normally high variants)
  - Rectal manipulation will not elevate PSA.
- Age-/race-adjusted "normal" PSA values (ng/mL):

Age	Asians	Blacks	Whites
40-49	0-2.0	0-2.0	0-2.5
50-59	0-3.0	0-4.0	0-3.5
60-69	0-4.0	0-4.5	0-4.5

70-79    0-5.0    0-5.5    0-6.5

- 5- $\alpha$ -Reductase inhibitors decrease PSA by  $\div$ 50%.
- Other PSA metrics used to aid in CaP diagnosis: PSA velocity, PSA doubling time, PSA density, percentage free PSA
  - Total PSA velocity:  $\geq$ 0.75 ng/mL/year or  $>$ 20% baseline for higher values increases CaP risk
  - Free PSA and age/race-adjusted PSA helpful in evaluating risk
  - PSAD (PSA density)  $\geq$ 0.15 associated with higher prevalence of CaP
- PSA/free PSA and probability of cancer:

PSA (ng/dL)	Cancer Rate	% Free PSA (for PSA 4-10)	Cancer Rate
0-2	1%	0-10%	56%
2-4	15%	10-15%	28%
4-10	25%	15-20%	20%
>10	>50%	20-25%	16%
		>25%	8%

- Prostate biopsy
  - Decision to biopsy involves PSA, DRE findings, and overall clinical suspicion of CaP.
  - Standard biopsy includes systematic random cores from the peripheral zone-base, mid, and apex, generally 8 to 12 cores.
  - The Gleason Grade is the standard pathologic grading system:
    - Ranks specimens from 1 to 5 based on architectural pattern identified, with 1 being most differentiated and 5 being least.
    - Primary and secondary patterns are identified and reported, and the sum is the Gleason score (e.g., 3 + 4 = 7).
    - Most prostate cancer is scored 6 to 10 with 10 having the worst prognosis.
- Staging
  - TNM (tumor, node, and metastasis) staging is used to generate a clinical and pathological stage, which primarily directs treatment. Clinical staging is as follows:

- T1: cancer found incidentally on TURP or found on biopsy for elevated PSA
- T2: cancer found on DRE but confined to the prostate
- T3: cancer found to be extended locally outside of the prostate and/or the seminal vesicle
- T4: invading adjacent organs
- N1: denotes local lymph node spread
- M1: distant metastasis

### *Follow-Up Tests & Special Considerations*

- Bone scan and/or CT scan and/or MRI may be indicated for high-risk cancers.
- Biopsy if suspicious nodal findings
- Alkaline phosphatase associated with bony mets
- Genetic testing (e.g., Prolaris, Oncotype Dx, etc.) is emerging as a prognostic modality.

## **TREATMENT**

Treatment options include:

- Watchful waiting: monitoring with expectation to provide palliation with symptoms
- Active surveillance: close monitoring of PSA, DRE, and repeat biopsy at regular intervals (3)
- Radical prostatectomy: ± pelvic lymph node dissection (PLND)
- Radiation therapy: external beam (EBRT)
- Brachytherapy: radioactive implants placed in prostate; option for early clinical stage localized to the prostate
- Androgen deprivation therapy (ADT) may be surgical or nonsurgical:
  - Bilateral orchiectomy (surgical castration)
  - Gonadotropin-releasing hormone (GnRH) agonist, antagonist, or antiandrogen (medical castration)
- Chemotherapy: includes multiple chemotherapeutic agents used to treat castrate resistant prostate cancer

## RISK STRATIFICATION

- Treatment options based upon risk: low, intermediate, and high-risk categories; this is based on risk of recurrence after definitive treatment. Must meet all three criteria to be low risk; any one criterion moves patient to a higher risk group (4)[A]:

Risk Category	Clinical Stage	Serum PSA	Gleason Score
Low	T1-T2a	<10 ng/mL	≤6
Intermediate	T2b-T2c	>10 and ≤20 ng/mL	7
High	T3a	>20 ng/mL	8-10

- Localized CaP
  - Low risk:
    - Mainstay of therapy is active surveillance.
    - Radical prostatectomy and radiation therapy may be offered.
  - Intermediate risk:
    - Mainstay of therapy is radical prostatectomy with LND or radiation therapy.
    - Radical prostatectomy has shown a survival benefit in intermediate and high risk prostate cancer (5)[A]
  - High Risk:
    - Mainstay of therapy is radical prostatectomy or radiation therapy.
    - Adjuvant radiation may be considered based on adverse pathologic findings after prostatectomy

### ALERT

- Life expectancy determinations as well as educating the patient of the risks and benefits of surveillance and treatment options is critical.

- Locally advanced CaP:
  - Mainstay of therapy is ADT and radiation. Surgery and adjuvant radiation may also play a role.
- Metastatic CaP:
  - Mainstay of therapy is RT and ADT.

- ADT specifics:
  - GnRH agonists include leuprolide or goserelin.
  - GnRH antagonists include degarelix: an alternative to GnRH agonists; suppresses testosterone production and avoids flare phenomenon observed with GnRH agonists
  - Side effects of ADT: osteoporosis, gynecomastia, erectile dysfunction (ED), decreased libido, obesity, lipid alterations, greater risk of diabetes, and cardiovascular disease
  - Flare phenomenon (disease flare: hot flashes, fatigue) can occur owing to transient increase in testosterone levels on initiation of GnRH agonist therapy.
  - If spinal cord metastases are present, the concern for cord compression with a testosterone flare can be avoided by starting antiandrogen therapy prior to initiation of a GnRH agonist.
  - Combined androgen blockade with GnRH agonist and antiandrogen (e.g., bicalutamide, nilutamide, or flutamide) may be used to prevent flare.
- Castration-resistant prostate cancer (CRPC)
  - CRPC is defined as progression of disease following ADT. Treatment includes the following:
    - Nonmetastatic
      - Continue ADT, no further treatment has been shown to increase overall survival.
      - Antiandrogen or androgen synthesis inhibitor (e.g., ketoconazole) may be added.
    - Asymptomatic metastatic: no previous therapy with docetaxel:
      - Abiraterone: inhibitor of CYP17A (adrenal androgen production), used with prednisone
      - Enzalutamide: androgen receptor inhibitor
      - Docetaxel: chemotherapeutic that inhibits microtubules
      - Sipuleucel-T: immunotherapy
    - Symptomatic metastatic: no previous therapy with docetaxel:
      - Abiraterone, enzalutamide, docetaxel
      - Radium-223 (radiopharmaceutical) for patients with symptomatic bony metastases and no visceral metastasis.
    - Symptomatic metastatic: previous therapy with docetaxel:
      - Good performance status: abiraterone, enzalutamide, cabazitaxel

- Poor performance status: Mainstay is palliative care, may attempt further therapy based on patient wishes.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- Prostatectomy: PSA and DRE are recommended at regular intervals. PSA threshold defining biochemical recurrence is evolving; however, recent data suggests a cutoff of 0.2 ng/mL (4). A CT and bone scan are usually obtained. If the PSA recurrence is thought to be from local disease, salvage radiation is considered. For metastatic disease, androgen deprivation is considered.
- XRT: PSA and DRE are recommended at regular intervals. Biochemical recurrence is defined as PSA increase  $\geq 2$  ng/mL above nadir, a CT and bone scan are usually obtained. If the PSA recurrence is thought to be from local disease, salvage prostatectomy or cryosurgery is considered. For metastatic disease, androgen deprivation is considered.

### *PROGNOSIS*

- Localized disease is frequently curable; advanced disease has a favorable prognosis if lesions are hormone-sensitive.
- 5-year CaP survival by stage: local 100%, regional 100%, distant 28%
- Recurrence risk increased if adverse pathologic features are present: extraprostatic extension, seminal vesicle invasion, positive surgical margins

### **COMPLICATIONS**

- Prostatectomy: Urinary incontinence and ED are the most common long-term issues.
- Radiation therapy: urinary incontinence, ED, radiation cystitis, and radiation proctitis
- Treatment options for ED: PDE5 inhibitors, intracavernosal injections, intraurethral suppositories, vacuum pump, penile prosthesis
- Treatment options for incontinence: oral medications, urethral slings, artificial sphincters

## Codes

&NA;

### ICD10

C61 Malignant neoplasm of prostate

## Clinical Pearls

&NA;

- Prostate cancer is clinically diverse, ranging from low-risk/indolent disease to high-risk/aggressive disease.
- Most men with CaP are asymptomatic.
- The use of PSA for CaP screening is controversial and necessitates an open conversation between medical provider and patient regarding benefits/risks.
- Active surveillance is an important treatment option to consider for low-risk patients.
- In patients taking 5- $\alpha$ -reductase inhibitors, PSA level to estimate actual PSA.

# Prostatic Hyperplasia, Benign (BPH)

Sara M. DeSpain, MD

James E. Hougas III, MD, Maj, USAF, MC

## BASICS

- Benign prostatic hyperplasia (BPH) is caused by a proliferation of both the smooth muscle and epithelial cell lines of the prostate which cause increased volume and can cause compression of the urethra and obstructive symptoms.
- Clinically presents with storage and/or voiding symptoms commonly referred to as lower urinary tract symptoms (LUTS). These include difficulty initiating stream, frequency, or dysuria.
- Symptoms do not directly correlate to prostate volume. Estimated that half of all men with histologic evidence of BPH experience moderate to severe LUTS.
- Progression may result in upper and lower tract infections and may progress to direct bladder outlet obstruction and acute renal failure (ARF).

## EPIDEMIOLOGY

Near universal development in men; age dependent

### *Incidence and Prevalence*

Incidence increases with age; wide variety of estimates of prevalence ranging from 70% to 90% by the age of 80 (estimated at 8-20% by age 40).

## ETIOLOGY AND PATHOPHYSIOLOGY

- Develops in prostatic periurethral or transition zone.
- Hyperplastic nodules of stromal and epithelial components increase glandular components.
- Etiology is unknown but recently there is a theory that it is from a reawakening of the embryonic induction process because of the similarity between BPH and the embryonic morphogenesis.

## COMMONLY ASSOCIATED CONDITIONS

- LUTS

- LUTS can be divided into two groups: filling/storage symptoms and voiding symptoms.
  - Filling/storage symptoms include frequency, nocturia, urgency, and urge incontinence.
  - Voiding symptoms include difficulty initiating stream, incomplete voiding, weak stream.
  - Can lead to acute or chronic obstructive symptoms
- Sexual dysfunction, including erectile dysfunction and ejaculatory disorders
- LUTS can also be secondary to cardiovascular, respiratory, or renal disease (1).

## RISK FACTORS

- Most significant risk factor is age.
- Increased risk of BPH with higher free prostate-specific antigen (PSA) levels, heart disease, and use of  $\alpha$ -blockers
- Obesity and lack of exercise can cause LUTS to be more significant.
- No evidence of increased or decreased risk with smoking, alcohol, or any dietary factors.
- Low androgen levels from cirrhosis/chronic alcoholism can reduce the risk of BPH.

## GENERAL PREVENTION

- The disease appears to be part of the aging process.
- Symptoms can be managed through weight loss, regulation of fluid intake, decreased intake of caffeine, and increased physical activity.

## DIAGNOSIS

### HISTORY

- Evaluate symptom severity with the American Urological Society Symptom Index or the International Prostate Symptom Score (IPSS).
- Screen for other causes of symptoms such as infection, procedural history, neurologic causes. Evaluate for comorbid conditions which may produce similar symptoms such as diabetes, CHF, or Parkinson disease.
- Review medication list. Pay particular attention to diuretics and anticholinergic medications. Also, decongestants (increased sphincter tone), opiates (impaired autonomic function), or tricyclic antidepressants (anticholinergic effects)
- Review family history for BPH and prostate cancer.

- Screen for gross hematuria. IPSS of LUTS, patient filled survey to follow severity (2)[A]:
  - Questionnaire: Over the past month, how often have you:
    - 1. Had the sensation of not emptying your bladder completely after you finished urinating?
    - 2. Had to urinate again <2 hours after you finished urinating?
    - 3. Found you stopped and started again several times when you urinated?
    - 4. Found it difficult to postpone urination?
    - 5. Had a weak urinary stream?
    - 6. Had to push or strain to begin urination?
    - 7. Been up to urinate from the time you went to bed at night until the time you got up in the morning?
    - 8. How would you feel if you were to spend the rest of your life with your current symptoms?
  - Scoring of the questionnaire:
    - Questions 1 to 6: no symptoms = 0 points, 1 in 5 times = 1 point, less than half = 2 points, about half = 3 points, more than half = 4 points, most of the time = 5 points
    - Question 7: no occurrence = 0 points, 1 time = 1 point, 2 times = 2 points, 3 times = 3 points, 4 times = 4 points, and 5 times or more = 5 points
    - Question 8: 0 = delighted, 1 = pleased, 2 = mostly satisfied, 3 = mixed, 4 = mostly dissatisfied, 5 = unhappy, 6 = terrible
    - Symptoms are classified as mild (total score 0 to 7), moderate (total score 8 to 19), and severe (total score 20 to 35).
- Nocturia >2 times per night, warrants a frequency/volume chart for 2 to 3 days to detect urinary patterns.

## PHYSICAL EXAM

- Digital rectal exam (DRE) finding of symmetrically enlarged prostate, but *size does not always correlate with symptoms*.
- Signs of renal failure due to obstructive uropathy (edema, pallor, pruritus, ecchymosis, nutritional deficiencies)
- If DRE is suggestive of prostate cancer, there is hematuria, recurrent infections, concern for

stricture, or evidence of neurologic disease, the patient should be referred to urology.

## *DIFFERENTIAL DIAGNOSIS*

- Obstructive
  - Prostate cancer
  - Urethral stricture or valves
  - Bladder neck contracture (usually secondary to prostate surgery)
  - Inability of bladder neck or external sphincter to relax appropriately during voiding
- Neurologic
  - Spinal cord injury
  - Stroke
  - Parkinsonism
  - Multiple sclerosis
- Medical
  - Poorly controlled diabetes mellitus
  - Congestive heart failure (CHF)
- Pharmacologic
  - Diuretics
  - Decongestants
  - Anticholinergics
  - Opioids
  - Tricyclic antidepressants
- Other:
  - Bladder carcinoma
  - Overactive bladder
  - Nocturnal polyuria (>33% of the 24-hour urine volume occurs at night)
  - Bladder calculi
  - UTI

- Prostatitis
- Urethritis/sexually transmitted infections
- Obstructive sleep apnea (OSA) (nocturia)
- Caffeine
- Polyuria (either isolated nocturnal polyuria or 24-hour polyuria)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Urinalysis (UA) in all patients presenting with LUTS, can help rule out other etiologies such as bladder stones, cancer, UTI, or urethral strictures
- PSA should be offered to all men with a life expectancy of 10 years and who would be surgical candidates if prostate cancer was identified.
- PSA levels also correlate with prostate volume which can help guide treatment choice.
- With bladder cancer risk factors (smoking history or hematuria) obtain urine cytology
- If nocturia is the main concern, consider using a frequency volume chart for urine output.
- Sleep study if OSA or primary nocturnal polyuria is suspected.
- Serum creatinine measurement is not recommended. (AUA recommendation).

### *Follow-Up Tests & Special Considerations*

- No further testing that is recommended in uncomplicated LUTS; further testing when symptoms that do not respond to medical management or if initial evaluation suggests underlying disease.
- Uroflow: volume voided per unit time (peak flow <10 mL/s is abnormal)
- Postvoid residual: either with catheterization or bladder ultrasound (>100 mL = incomplete emptying)
- Transrectal ultrasound: assessment of gland size; not necessary in the routine evaluation
- Abdominal ultrasound: can demonstrate increased postvoid residual or hydronephrosis; not necessary in the routine evaluation

### *Diagnostic Procedures/Other*

- Pressure-flow studies (urine flow vs. voiding pressures) to determine etiology of symptoms

Obstructive pattern shows high voiding pressures with low flow rate.

- Cystoscopy
  - Demonstrates presence, configuration, cause (stricture, stone), and site of obstructive tissue
  - May help determine therapeutic option
  - Not recommended in initial evaluation unless other factors, such as hematuria, are present.

---

P.857

## TREATMENT

### GENERAL MEASURES

- Treatment ranges from watchful waiting to lifestyle modifications, medications, or surgical management.
- Mild symptoms (score of <7) or moderate symptoms (score 8 to 15) that are non-bothersome require no treatment. Reevaluate annually.
- For moderate to severe symptoms, try lifestyle interventions regulation of fluid intake, avoidance of alcohol and caffeine, exercise, diet, and eliminating/reducing contributing medications.
- Medical treatment requires interval follow-up of 2 to 4 weeks for  $\alpha$ -blockers and 3 months for 5- $\alpha$ -reductase inhibitors until symptoms improved, then annually.
- Patients with complications including obstruction and urinary retention require bladder drainage.

### MEDICATION

- Should be used as additive therapy, lifestyle modifications are still encouraged.
- Two main classes of medications:  $\alpha$ -adrenergic antagonists and 5- $\alpha$ -reductase inhibitors.
- The combination of these two medication classes is effective for long-term management of BPH and demonstrated large prostates.
  - **$\alpha$ -Adrenergic antagonists**
    - Are the first line option for moderate to severe bothersome LUTS. Affect contraction of smooth muscle in the prostatic urethra and bladder neck. Show benefit over placebo.

Typically take 2 to 4 weeks to show improvement. May affect blood pressure; requires dose titration and blood pressure monitoring. AUA recommends alfuzosin (Uroxatral), doxazosin (Cardura), and tamsulosin (Flomax) as they are thought to be more selective and have less effect on blood pressure. Prazosin (Minipress) and phenoxybenzamine (Dibenzylamine) have insufficient evidence and are not recommended. Most common adverse effect is dizziness. May cause orthostatic hypotension

- Doxazosin (**Cardura**): 1 to 8 mg/day PO. May delay the occurrence of acute urinary retention but does not decrease incidence.
- Tamsulosin (**Flomax**): 0.4 to 0.8 mg/day PO
- Alfuzosin (Uroxatral): 10 mg/day PO
- **Terazosin (Hytrin)**: Start at 1 mg PO daily at bedtime, max 20 mg daily.

○ **Contraindications:**

- Use caution in patients who are also using phosphodiesterase type 5 inhibitors for erectile dysfunction.
- Do not use in men pursuing cataract surgery until they are postoperative due to the risk for perioperative floppy iris syndrome.

■ **5- $\alpha$ -reductase inhibitors**

- Block conversion of testosterone to dihydrotestosterone, gradually reduce prostatic volume therefore are of most benefit when prostate volume exceeds 40 mL. Require 6 months to show clinical benefit. Two equally effective options:
    - Finasteride (Proscar): 5 mg/day PO
    - Dutasteride (Avodart): 0.5 mg/day PO
  - Used in patients with refractory hematuria after other causes have been ruled out
  - Should not be used in patients without evidence of enlarged prostates
  - Show reduced risk of acute urinary retention, less need for surgical intervention and less overall incidence of prostate cancer.
  - Side effects include decreased libido and erectile dysfunction.
- A PSA value in a patient taking a **5- $\alpha$ -reductase inhibitors will be artificially low.**
  - Combination therapy of  $\alpha$ -blocker plus 5- $\alpha$ -reductase inhibitor is equal to  $\alpha$ -blocker therapy, but superior to monotherapy among men with large prostates. Combination therapy is superior to monotherapy to prevent progression but increase risk of drug-related adverse events.

- Anticholinergic agents are appropriate for irritative LUTS without an elevated postvoid residual (PVR). Options include Solifenacin (Vesicare), Tolterodine (Detrol LA), or Oxybutynin (Ditropan XL). Should be avoided in patients with PVR >250 mL
- If patient also experiences erectile dysfunction phosphodiesterase-5 inhibitors have been shown to have mild improvement of LUTS. Can use Tadalafil (Cialis): 5 mg/day PO but avoid use in combination with  $\alpha_1$ -blockers or in those with CrCl <30 mL/min.

## *Geriatric Considerations*

Drugs to use with caution: anticholinergics, antihistamines, sympathomimetics, tricyclic antidepressants, opioids

## *ISSUES FOR REFERRAL*

- Moderate or severe LUTS that does not respond to medical management.
- BPH related complications such as recurrent UTIs or hematuria, renal insufficiency, and urinary retention.
- Abnormal PSA or prostate exam
- Any history of urethral trauma or stricture, or neurologic disease of the bladder/urinary system

## *SURGERY/OTHER PROCEDURES*

- Indications for surgery:
  - Urinary retention due to prostatic obstruction, recurrent, no improvement with medications
  - Intractable symptoms due to prostatic obstruction AUA score >8 and symptoms
  - Obstructive uropathy (renal insufficiency)
  - Recurrent or persistent UTIs due to prostatic obstruction
  - Recurrent gross hematuria due to enlarged prostate
  - Bladder calculi
- Surgical procedures: TURP remains the gold standard of surgical procedures; however for select patient populations, there are other options available.
- Common complications of TURP:
  - Bleeding can be significant.
  - TUR syndrome: hyponatremia secondary to absorption of hypotonic irrigation fluid
  - Retrograde ejaculation

- Urinary incontinence
- Other options include transurethral needle ablation (TUNA) and transurethral microwave thermo-therapy (TUMT), or transurethral incision of the prostate (TUIP). Open prostatectomy is more common when prostate exceeds 100 g. Transurethral laser ablation is an alternative option for patients on anticoagulants.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

Saw palmetto (*Serenoa repens*) has been thoroughly studied in a subject in Cochrane review, and did not improve LUTS. Other agents including pygeum, cernilton, and herbs with beta sitosterols have been studied less however no current evidence to support their use. Acupuncture failed to show improvement in LUTS in one clinical trial as well. There are no recommended complementary or alternative treatments for BPH.

## ONGOING CARE

### *Patient Monitoring*

- Symptom index (IPSS) monitored every 3 to 12 months.
- DRE yearly
  - PSA yearly: should not be checked while patient is in retention, recently catheterized, or within a week of any surgical procedure to the prostate
  - Consider monitoring PVR, if elevated.

### *DIET*

Avoid large boluses of oral or IV fluids or alcohol intake, caffeine may exacerbate symptoms as well.

### *PATIENT EDUCATION*

National Kidney and Urologic Diseases Information Clearinghouse, Box NKUDIC, Bethesda, MD 20893; 301-468-6345

### *PROGNOSIS*

- Symptoms improve or stabilize in 70-80% of patients.
- 25% of men with LUTS will have persistent storage symptoms after prostatectomy.
- Of men with BPH, 11-33% have occult prostate cancer.

## COMPLICATIONS

- Urinary retention (acute or chronic)
- Bladder stones
- Prostatitis
- Hematuria

## REFERENCES

## Codes

&NA;

## ICD10

- N40.0 Enlarged prostate without lower urinary tract symptoms
- N40.1 Enlarged prostate with lower urinary tract symptoms

## Clinical Pearls

&NA;

- Although medical therapy has changed the management of BPH, it has only delayed the need

for TURP by 10 to 15 years, not eliminated it.

- Urinary retention, obstructive uropathy, recurrent UTIs, elevated PSA, bladder calculi, hematuria, and failure of medical therapy are indications for surgical management of BPH.

# Prostatitis

Kyle Stephens, DO, MPH

Vincent Lo, MD, FAAFP

## BASICS

### DESCRIPTION

- Painful or inflammatory condition affecting the prostate gland with or without bacterial etiology, often characterized by urogenital pain, voiding symptoms, and/or sexual dysfunction
- Significant impact on quality of life
- <10% bacteria-proven infection
- National Institutes of Health's classification
  - *Class I: Acute bacterial prostatitis*: symptomatic with fever, perineal pain, dysuria, and obstructive symptoms; polymorphonuclear leukocytes (PMNL) and bacteria in urine
  - *Class II: Chronic bacterial prostatitis*: symptomatic chronic or recurrent bacterial infection with pain and voiding disturbances; PMNL and bacteria in expressed prostatic secretions (EPS), or urine after prostate massage, or in semen
  - *Class III: Chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS)*
    - Inflammatory (Subtype IIIA): chronic symptoms with PMNL in EPS/urine after prostate massage or in semen
    - Noninflammatory (Subtype IIIB): chronic symptoms without presence of PMNL in EPS/urine after prostate massage or in semen
  - *Class IV: Asymptomatic inflammatory prostatitis*: incidental finding during prostate biopsy for infertility, cancer workup; presence of PMNL and/or bacteria in EPS/urine after prostatic massage or in semen
- System(s) affected: genitourinary, renal, reproductive

### EPIDEMIOLOGY

#### Incidence

Two million cases annually in the United States

- Predominant age: 30 to 50 years old, sexually active; chronic is more common in those >50 years.
- Bacterial prostatitis occurs more frequently in patients with HIV.

## Prevalence

- Affects approximately 8.2% of males (1)
- Lifetime probability of diagnosis >25% (1)
- Accounts for 8% of visits to urologists and 1% of visits to primary care physicians (2)
- Percentage of cases by class: Class I: <1%, Class II: 5-10%, Class III: 80-90%, Class IV: 10% (3)

## ETIOLOGY AND PATHOPHYSIOLOGY

- Acute bacterial prostatitis (Class I)
  - Likely, etiology from ascending urethral infection with intraprostatic reflux of infected urine into prostatic ducts, often associated with cystitis
  - Can occur after instrumentation of prostate
  - Usually gram-negative bacteria (*Escherichia coli* (most common); *Proteus*, *Klebsiella*, *Serratia*, and *Enterobacter* species; *Pseudomonas aeruginosa*)
  - Rarely, gram-positive bacteria (*Staphylococcus aureus*, *Streptococcus*, and *Enterococcus* species).
  - Confirmed *Staphylococcal* prostatitis should warrant evaluation for hematogenous spread, including endovascular source.
  - Atypical bacteria include *Chlamydia trachomatis*, *Trichomonas vaginalis*, and *Ureaplasma urealyticum*.
  - Consider *Neisseria gonorrhoeae* or *Chlamydia trachomatis* in sexually active men <35 years.
- Chronic bacterial prostatitis (class II)
  - Similar pathogens as discussed earlier
  - Often occurs as recurrent episodes of infection by same organism
  - Progression from acute to chronic prostatitis is poorly understood but could result from inadequate treatment of acute prostatitis.
- CP/CPPS (class III)

- Unclear etiology, possibly due to difficult-to-culture infection
- Inciting agent may cause inflammation or neurological damage in or around the prostate and lead to pelvic floor neuromuscular and/or neuropathic pain.

## *RISK FACTORS*

- Urinary tract infections
- HIV infection
- Prostatic calculi
- Urethral stricture
- Urinary catheterization: indwelling, intermittent
- Genitourinary instrumentation including prostate biopsy (especially in patients with prior quinolone intake), transurethral resection of prostate, cystoscopy
- Urinary retention
- Benign prostatic hypertrophy
- Unprotected sexual intercourse
- Trauma (e.g. bicycle, horseback riding)

## *GENERAL PREVENTION*

Antibiotic prophylaxis for genitourinary instrumentation and prostatic biopsy

## *COMMONLY ASSOCIATED CONDITIONS*

- Benign prostatic hypertrophy
- Cystitis
- Urethritis
- Sexual dysfunction

## **DIAGNOSIS**

### **HISTORY**

- Acute prostatitis (class I):
  - Acutely ill with fever, chills, malaise

- Low back pain, myalgias
- Frequency, urgency, dysuria, nocturia
- Prostatodynia, pelvic pain, perineal pain
- Cloudy urine
- Obstructive voiding symptoms: poor stream, hesitancy
- Chronic prostatitis (classes II and III):
  - More insidious presentation than Class I
  - Symptoms for 3 of 6 previous months
  - Low-grade fever (class II only)
  - Prostatodynia, perineal pain
  - Dysuria, frequency, urgency
  - Lower abdominal pain
  - Low back, testicular, and/or penile pain
  - Hematospermia
  - Sexual dysfunction/painful ejaculation

## *PHYSICAL EXAM*

- Vital signs (unstable vitals suggest sepsis)
- Back exam (CVA tenderness)
- Abdominal exam (bladder distension)
- Prostate exam
  - Class I: Prostate is very tender, warm, firm, edematous.
  - Class II: Often normal but enlarged, tender, edematous, nodular prostate also encountered
  - Class III: Often normal prostate

## **ALERT**

Avoid vigorous massage of the prostate in acute bacterial prostatitis; may induce iatrogenic bacteremia, safe if done gently

## *DIFFERENTIAL DIAGNOSIS*

- Lower urinary tract infection
- Pyelonephritis

- Cystitis (bacterial, interstitial)
- Urethritis
- Prostatic abscess
- Acute/chronic urinary retention
- Benign prostatic hypertrophy Malignancy (prostate, bladder)
- Obstructive calculi
- Foreign body

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Suspected acute prostatitis (Class I)
  - Urinalysis; urine Gram stain/culture and sensitivity
  - CBC with differential; blood culture if fever, chills, or signs of sepsis are present
- Suspected chronic bacterial prostatitis (class II)
  - Urinalysis; urine/EPS/semen: Gram stain/culture and sensitivity
  - Review previous urine culture results.
  - National Institute of HealthÑChronic Prostatitis Symptom Index (NIH-CPSI): 9-question symptom survey (<http://www.prostatitis.org/symptomindex.html>)
  - Diagnostic gold standard: Meares-Stamey 4-glass test (not performed often)
  - 2-glass test (pre- and postmassage urine testing) more common and easier with equivalent sensitivity and specificity (4)
    - Cultures of mid-stream preprostate massage urine and EPS/postmassage urine
  - Consider urinary flow rate and postvoid residual volume if urinary retention is present.
- Suspected CP/CPPS (class III)
  - Diagnosis of exclusion
  - Urinalysis; urine/EPS/semen: Gram stain/culture and sensitivity
  - Hematuria if present: urine cytology, cystoscopy, CT urography with or without contrast
  - PSA is not indicated unless malignancy is suspected.
  - Concomitant abdominal pain: CT abdomen

- Testicular pain: scrotal US
- Sensation of incomplete bladder emptying: postvoid residual volume with bladder US or catheterization
- Lumbar radiculopathy: MRI spine

### *Follow-Up Tests & Special Considerations*

- Failure to respond to initial antibiotic therapy: US, CT, or MRI to image prostate and urology referral
- US or CT or MRI if prostatic calculi, malignancy, or abscess are suspected
- Acute bacterial: urinalysis and culture 30 days after initiating treatment
- Chronic bacterial: urinalysis and culture every 30 days (may take several months of treatment to clear)

---

P.859

### *Diagnostic Procedures/Other*

- Needle biopsy or aspiration for culture
- Urodynamic testing (prostatodynia) if indicated
- Cystoscopy (in persistent nonbacterial prostatitis to rule out bladder cancer, interstitial cystitis)

## **TREATMENT**

### *GENERAL MEASURES*

- Analgesics/antipyretics/stool softeners
- Hydration
- Sitz baths to relieve pain and spasm
- Suprapubic catheter for urinary retention
- Anxiolytics, antidepressants if anxiety and/or depression are present

### *MEDICATION*

#### *First Line*

- Acute bacterial (outpatient) (3)[A]

- Fluoroquinolone (ciprofloxacin 500 mg PO q12h or levofloxacin 500 mg PO once daily) for 2 to 4 weeks *or*
- Trimethoprim-sulfamethoxazole 1 double-strength tab PO q12h for 2 to 4 weeks *or*
- If gram-positive cocci are seen in initial urine Gram stain, start with amoxicillin 500 mg PO q8h. Adjust antibiotics once culture and sensitivities report is available.
- Local sensitivity pattern should guide therapy.
- Ceftriaxone 250 mg IM 1 dose plus doxycycline 100 mg PO q12h daily for 1 week *or* (azithromycin 1 g PO single dose if at risk for sexually transmitted infection (STI) pathogens
- Acute bacterial (inpatient) (3)[A]
  - Ampicillin 2g IV q6h *or* fluoroquinolone (ciprofloxacin 400 mg IV q12h *or* levofloxacin 500 mg q24h); begin oral therapy after afebrile for 24 to 48 hours
- Chronic bacterial (class II) (3,5,6)[A],(7)[C]
  - Fluoroquinolone (e.g., levofloxacin 500 mg PO) once daily for 4 weeks *or* ciprofloxacin 500 mg PO q12h for 4 to 12 weeks
  - Combination therapy with azithromycin may help to eradicate atypical pathogens.
  - Anti-inflammatory agents for pain symptoms and  $\alpha$ -blockers for urinary symptoms
- CP/CPPS (class III) (8,9)[A],(7)[C]
  - No universally effective treatment
  - Treatment choice is patient-centered focusing on symptoms relief of four domains: pain, lower urinary tract symptoms (LUTS), psychological stress, and sexual dysfunction.
    - $\alpha$ -Blockers, antibiotics, and combinations of these therapies achieve greatest improvement in clinical symptoms scores compared to placebo.
    - Tamsulosin 0.4 mg PO once daily at bedtime for 4 to 6 weeks. Continue if there is a positive response.

## Second Line

- Piperacillin *or* ticarcillin with aminoglycoside, erythromycin, tetracycline, cephalexin, fluoroquinolones, (dicloxacillin, nafcillin IV, vancomycin IV
- Finasteride (in patients >45 years, class IIIA, and enlarged prostate glands)
- Atypical: may benefit from erythromycin, doxycycline

## ***ISSUES FOR REFERRAL***

Urology referral if antibiotic treatment fails, symptoms persist (especially obstructive voiding symptoms), hematuria, elevated PSA, or for surgical drainage if an abscess persists after 31 week of therapy

## ***ADDITIONAL THERAPIES***

- Psychotherapy if sexual dysfunction is present
- 5- $\alpha$ -reductase inhibitors, nonsteroidal anti-inflammatory medications, pelvic floor physical therapy, transurethral microwave thermotherapy (7)[C]

## ***SURGERY/OTHER PROCEDURES***

Surgical resection for intractable chronic disease or to drain an abscess (7)[C]

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Class III: Acupuncture, phytotherapies (pollen extract, quercetin), heat therapy, and myofascial release have limited data to support (7)[C],(10)[A].

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Proven or suspected abscess
- Unstable vital signs (sepsis)
- Immunocompromised
- Failed outpatient treatment

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Negative urine culture at 7 days predictive of cure after completion of treatment course
- Consider prostatic abscess in patients who do not respond well to therapy.

### ***Patient Monitoring***

NIH Chronic Prostatitis Symptom Index (NIH-CPSI): 9 questions, which can be used to evaluate severity of patient symptoms and response to treatment within three domains:

- Pain
- Urinary symptoms
- Quality of life

## **PROGNOSIS**

- Fever and dysuria usually resolve in 2 to 6 days.
- Acute infection usually improves in 3 to 4 weeks.
- Course of chronic prostatitis is often prolonged and difficult to cure; 55-97% cure rate depending on population and drug used
- 20% have reinfection or persistent infection.

## **COMPLICATIONS**

- Prostatic abscess (common in HIV-infected)
- Pyelonephritis
- Gram-negative sepsis, bacteremia
- Urinary retention
- Epididymitis
- Infertility
- Chronic bacterial prostatitis (following acute prostatitis)
- Metastatic infection (spinal, sacroiliac)

## See Also

&NA;

- Prostate Cancer; Prostatic Hyperplasia, Benign (BPH); Urinary Tract Infection (UTI) in Males
- Algorithm: Hematuria

## Codes

&NA;

### ICD10

- N41.9 Inflammatory disease of prostate, unspecified
- N41.0 Acute prostatitis
- N41.1 Chronic prostatitis

# Clinical Pearls

**&NA;**

- Vigorous prostatic massage is contraindicated in acute prostatitis.
- Antibiotic therapy is not proven to be effective in CP/CPPS (Class III) (8).
- At least 14 to 30 days of antibiotic therapy is required for acute prostatitis; longer for chronic bacterial prostatitis
- Imaging is often not needed.

# Protein C Deficiency

Elie Chalhoub, MD

Dalia Hammoud, MD

Maissaa Janbain, MD

## BASICS

### DESCRIPTION

- Protein C is a vitamin K-dependent factor made by the liver that becomes activated when thrombin binds to the endothelial receptor thrombomodulin.
- Activated protein C, with protein S as a cofactor, inactivates factors Va and VIIIa.
- Patients with protein C deficiency have a thrombotic disorder that primarily affects the venous system but can also affect the arterial system.
- System(s) affected: cardiovascular, hemic/lymphatic/immunologic, pulmonary

### EPIDEMIOLOGY

#### Prevalence

- 0.3% of normal individuals
- 4-5% of persons with venous thrombosis (VT)
- Predominant age: Mean age of first thrombosis is 45 years.
- Predominant sex: male = female

### ETIOLOGY AND PATHOPHYSIOLOGY

- Polymorphisms in the promoter region of the protein C gene can affect antigen levels. At least 150 mutations have been described in the protein C gene that can lead to functional deficiency.
- New mutations have been described associated with late-onset cerebral thrombosis (1).
- Acquired protein C deficiency can occur with liver disease, ARDS, DIC, chemotherapy with L-asparaginase, 5-FU, methotrexate, and cyclophosphamide, as well as postoperative state and severe infections, especially meningococemia. Also, rare patients can develop inhibitors to

activated protein C. Neonates have lower levels of protein C than adults.

## *Genetics*

Patients heterozygous for protein C deficiency who start warfarin without concomitant heparin can develop warfarin-induced skin necrosis because the half-life of other vitamin K-dependent clotting factors, prothrombin, factor IX, and factor X is much longer than that of protein C (4 to 8 hours). These patients develop extremely low levels of protein C and sub-sequently increased thrombin generation, leading to necrosis of the skin over central areas of the body such as the breast, abdomen, buttocks, and genitalia (2)[A].

## **GENERAL PREVENTION**

Because protein C deficiency is a congenital disease, there are no preventive measures.

## **COMMONLY ASSOCIATED CONDITIONS**

- Deep and superficial venous thrombosis, often spontaneous
- Up to 50% of homozygotes will have thrombosis.
- Homozygosity is associated with catastrophic thrombotic complications at birth (e.g., *purpura fulminans*).
- Sites of thrombosis can be unusual, including the mesentery and cerebral veins, especially when combined with other risk factors such as oral contraceptives.
- Arterial thrombosis is rare.
- Skin necrosis can be seen in patients on warfarin.
- Recurrent pregnancy losses

## **DIAGNOSIS**

### **HISTORY**

- VT at <40 years of age without another etiology
- Thrombosis in unusual locations (e.g., mesentery, sagittal sinus, portal vein)
- Family history of thrombosis or spontaneous abortion

### **PHYSICAL EXAM**

Normal

# DIFFERENTIAL DIAGNOSIS

- Factor V Leiden (causes resistance to activated protein C, not a deficiency of protein C)
- Protein S deficiency
- Antithrombin deficiency
- Dysfibrinogenemia
- Dysplasminogenemia
- Homocystinemia
- Prothrombin 20210 mutation
- Elevated factor VIII levels

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- For evaluation of new clot in patient at risk (see History): CBC with peripheral smear, PT/INR, aPTT, thrombin time, lupus anticoagulant, antiphospholipid antibodies, factor VIII, anticardiolipin antibody, anti-β<sub>2</sub>-glycoprotein I antibody, activated protein C resistance, protein S antigen and resistance, antithrombin III assay, fibrinogen, factor V Leiden, prothrombin G20210A, homocysteine
- Protein C activity assay using a snake venom protease to activate protein C
- Immunoassay for quantitative assessment of protein C level
- Drugs that may alter lab results
  - Oral contraceptives can raise protein C levels.
  - Warfarin reduces protein C levels.
  - Patients should be off warfarin for 2 to 3 weeks before reliable testing (3)[C].
- Disorders that may alter lab results
  - Liver disease reduces protein C levels.

### **ALERT**

Acute thrombosis can lower protein C levels. Repeat confirmatory test of low protein C level at a separate time is advisable. If a normal level of protein C is obtained at presentation, then deficiency can be excluded.

## TREATMENT

Treat active thrombosis; follow-up.

### GENERAL MEASURES

- Routine anticoagulation for asymptomatic patients with protein C deficiency is not recommended (2)[A].
- Anticoagulation for 6 to 12 months is recommended for patients with protein C deficiency and a first thrombosis.
- Some argue for lifetime anticoagulation; data are limited.
- Anticoagulation for life is indicated for patients with protein C deficiency and recurrent thromboses.
- The role of family screening for protein C deficiency is unclear because most patients with this mutation do not have thrombosis. Screening should be considered for women considering using oral contraceptives or pregnancy and who have a family history of protein C deficiency (4)[B].
- Treatment with LMWH is recommended over unfractionated heparin, unless the patient has severe renal failure (5)[B].
- Treat as outpatient, if possible (5)[B].
- Initiate warfarin together with LMWH on the first treatment day, and discontinue LMWH after minimum of 5 days and two consecutive INRs >2 (5)[A].
- For pregnant women with no prior history of venous thromboembolism (VTE), we suggest antepartum and postpartum clinical vigilance. Postpartum prophylaxis for 6 weeks with prophylactic- or intermediate-dose LMWH is reserved only for patients with positive family history of VTE (3)[C],(5).

### MEDICATION

#### *First Line*

- Low-molecular-weight heparin (LMWH) (2)[A]: initially for a minimum of 5 days and two consecutive INRs between 2 and 3
  - Enoxaparin (Lovenox) 1 mg/kg SC BID or enoxaparin 1.5 mg/kg/day SC
  - Tinzaparin (Innohep): 175 anti-Xa IU/kg/day SC
  - Dalteparin (Fragmin) 200 U/kg/day

- Factor Xa inhibitors

- Fondaparinux (Arixtra) <50 kg: 5 mg/day SC; 50 to 100 kg: 7.5 mg/day SC; >100 kg: 10 mg/day SC; contraindicated if CrCl <30 mL/min

---

P.861

- Oral vitamin K antagonist: warfarin (Coumadin), per the most recent chest guidelines, 5mg/day PO then adjusted to an INR of 2 to 3 for at least 3 to 6 months (2)[A],(5)

- Novel oral anticoagulants (NOACs):

- Dabigatran 150 mg PO BID (after 5 to 10 days of parenteral anticoagulation)
- Rivaroxaban 15 mg PO BID for 21 days then 20 mg PO QD
- Apixaban 10 mg PO BID for 7 days then 5 mg PO BID
- Edoxaban 60 mg PO QD (after 5 to 10 days of parenteral anticoagulation)

- Contraindications

- Active bleeding precludes anticoagulation; risk of bleeding is a relative contraindication to long-term anticoagulation.
- Warfarin is contraindicated in patients with a prior history of warfarin-induced skin necrosis.

- Precautions

- Observe patient for signs of embolization, further thrombosis, or bleeding.
- Avoid IM injections.
- Periodically, check stool and urine for occult blood; monitor CBC, including platelets.
- Heparin: thrombocytopenia and/or paradoxical thrombosis with thrombocytopenia
- Warfarin: necrotic skin lesions (typically breasts, thighs, and buttocks)
- LMWH: Adjust dose in renal insufficiency.

- Significant possible interactions

- Agents that intensify the response to oral anticoagulants: alcohol, allopurinol, amiodarone, anabolic steroids, androgens, many antimicrobials, cimetidine, chloral hydrate, disulfiram, all NSAIDs, sulfapyrazone, tamoxifen, thyroid hormone, vitamin E, ranitidine, salicylates, acetaminophen
- Agents that diminish the response to oral anticoagulants: aminoglutethimide, antacids, barbiturates, carbamazepine, cholestyramine, diuretics, griseofulvin, rifampin, oral contraceptives

## *Second Line*

- Heparin 80 mg/kg IV bolus followed by 18 mg/kg/hr; adjust dose depending on PPT.
- In patients requiring large daily doses of heparin, measure an anti-Xa level for dose guidance.
- Alternatively, and for outpatients, unfractionated heparin can be given at 333 U/kg then 250 U/kg SC, without monitoring (5)[C].

## *ISSUES FOR REFERRAL*

Patients with suspected protein C deficiency should be seen by a hematologist.

However, screening and therefore prophylactic treatment of asymptomatic family members is not justified (6).

## *SURGERY/OTHER PROCEDURES*

- Anticoagulation must be held for surgical interventions.
- In patients with acute proximal DVT of the leg *and* an absolute contraindication to anticoagulation, inferior vena cava (IVC) filters are recommended; otherwise, the use of an IVC filter in addition to anticoagulants is not recommended in most patients with acute DVT of the leg (2)[B],(5).

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Life-threatening VT
- Significant bleeding while on anticoagulant therapy

### *Nursing*

Look for signs of bleeding while on anticoagulation therapy.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- Warfarin requires periodic (monthly after initial stabilization) monitoring of the INR to maintain a range of 2 to 3.

- LMWH is the treatment of choice in pregnancy. Periodic monitoring with anti-Xa levels is recommended in these patients.

## DIET

Unrestricted (except if on warfarin—avoid food with significant amounts of vitamin K)

## PATIENT EDUCATION

- Patients should be educated about the use of oral anticoagulant therapy if taking such.
- Avoid NSAIDs while on warfarin.
- Avoid OCPs, as they increase risk of thrombosis.

## PROGNOSIS

- When compared with normal individuals, persons with protein C deficiency have normal life spans.
- By age 45 years, 50% of the people heterozygous for protein C deficiency will have VT; half will be spontaneous.

## COMPLICATIONS

Recurrent thrombosis (requires indefinite anticoagulation)

## Codes

**&NA;**

### ICD10

D68.59 Other primary thrombophilia

## Clinical Pearls

**&NA;**

- Asymptomatic patients with protein C deficiency do not need prophylactic anticoagulation because the risk of thrombosis is low (6).
- Patients with protein C deficiency who have DVT should be anticoagulated for at least 6 months.

# Protein S Deficiency

Dalia Hammoud, MD

Elie Chalhoub, MD

Maissaa Janbain, MD

## BASICS

### DESCRIPTION

- Protein S is a vitamin K-dependent factor made principally by the liver that acts as a cofactor for protein C.
- Protein C becomes activated when thrombin binds to the endothelial receptor, thrombomodulin.
- Activated protein C, with protein S as a cofactor, inactivates clotting factors Va and VIIIa, and it enhances fibrinolysis.
- Protein S is also able to directly inhibit factors Va, VIIa, and Xa independently of activated protein C.
- Patients with protein S deficiency have a thrombotic disorder that primarily affects the venous system.
- System(s) affected: cardiovascular; hematologic/lymphatic/immunologic; pulmonary

### EPIDEMIOLOGY

#### *Incidence*

- Predominant age: Mean age of first thrombosis is the 2nd decade of life.
- Predominant sex: male = female

#### *Prevalence*

- 0.3% of normal individuals
- Found in 3% of persons with VT

### ETIOLOGY AND PATHOPHYSIOLOGY

- >131 mutations in the protein S gene leading to an inherited protein S deficiency have been described. Protein S reversibly binds to the C4b-binding protein. Only the free form acts as a cofactor for activated protein C. This leads to conditions in which free protein S is low, but total protein S is normal. These individuals are prone to thrombosis.
- Acquired protein S deficiency from decreased free protein S can occur during pregnancy; in patients taking oral contraceptives or warfarin; and in DIC, liver disease, nephrotic syndrome, inflammation, L-asparaginase chemotherapy, and acute thrombosis.
- Transient autoantibodies can develop to protein S in patients with acute varicella (1)[C].

## Genetics

Autosomal dominant. Heterozygotes have an odds ratio (OR) of venous thrombosis (VT) of 1.6 to 11.5. Arterial thrombosis is more frequent in patients with protein S deficiency who smoke. Homozygotes can have a fulminant thrombotic event in infancy, termed *neonatal purpura fulminans*. Homozygosity or compound heterozygosity, if untreated, is usually incompatible with adult life.

## RISK FACTORS

- Oral contraceptives, pregnancy, and the use of HRT increase the risk of VT in patients with protein S deficiency (2)[A].
- Patients with protein S deficiency and another prothrombotic state, such as factor V Leiden, have further increased rate of thrombosis (2)[A].
- Patients heterozygous for protein S deficiency who are initiated on warfarin without concomitant heparin can develop warfarin-induced skin necrosis because the half-life of other vitamin K-dependent clotting factors (e.g., prothrombin, factor IX, and factor X) is much longer than the anticoagulant protein S (4 to 8 hours), leading to a transient hypercoagulable state when protein S becomes depleted. These patients develop extremely low levels of protein S and develop necrosis of the skin over central areas of the body such as the breast, abdomen, buttocks, and genitalia (2)[A].

## Pregnancy Considerations

Increased thrombotic risk in patients with protein C deficiency

## GENERAL PREVENTION

Because protein S deficiency is a congenital disease, there are no preventive measures.

## COMMONLY ASSOCIATED CONDITIONS

- Deep and superficial VT, often spontaneous

- Up to 50% of homozygotes will have thrombosis.
- Homozygosity is associated with catastrophic thrombotic complications at birth: *neonatal purpura fulminans*
- Sites of thrombosis can be unusual, including the mesentery, cerebral veins, and axillary veins.
- Arterial thrombosis is rare, but reported in several case reports.
- Skin necrosis can be seen in patients on warfarin.
- Recurrent pregnancy losses (3).

## DIAGNOSIS

### HISTORY

Order testing for patients with VT at age <40 years without another etiology; thrombosis in unusual locations (e.g., mesentery, sagittal sinus, portal vein) with a family history of thrombosis or spontaneous abortion

### PHYSICAL EXAM

Normal

### DIFFERENTIAL DIAGNOSIS

- Factor V Leiden
- Protein C deficiency
- Antithrombin deficiency
- Dysfibrinogenemia
- Dysplasminogenemia
- Homocysteinemia
- Prothrombin 20210 mutation
- Elevated factor VIII levels

### DIAGNOSTIC TESTS & INTERPRETATION

#### *Initial Tests (lab, imaging)*

- For evaluation of new clot in patient at risk: CBC with peripheral smear, PT/INR, aPTT, thrombin time, lupus anticoagulant, antiphospholipid antibodies, factor VIII, anticardiolipin

antibody, anti-*β<sub>2</sub>*-glycoprotein I antibody, activated protein C resistance, protein S antigen and resistance, antithrombin III assay, fibrinogen, factor V Leiden, prothrombin G20210A, homocysteine

- Protein S activity assay (mainly after obtaining APC resistance)
- Immunoassay for quantitative assessment of total and free protein S levels. Test off vitamin K antagonists.
- Disorders that may alter lab results: Liver disease and pregnancy-reduce protein S levels.
- Total protein S levels are markedly decreased in newborns and young infants; use age-adjusted norms.

## TREATMENT

### GENERAL MEASURES

- Routine anticoagulation for asymptomatic patients with protein S deficiency is not recommended (2)[A].
- Anticoagulation for 6 to 12 months is recommended for patients with protein S deficiency and a first thrombosis.
- Some argue for lifetime anticoagulation; data are limited.
- Anticoagulation for life is indicated for patients with protein S deficiency and recurrent thrombosis.
- The role of family screening for protein S deficiency is unclear because most patients with this mutation do not have thrombosis. Screening should be considered for women considering oral contraceptives or pregnancy, and who have a family history of protein S deficiency (4)[B].
- Treatment of thrombosis with LMWH is recommended over unfractionated heparin, unless the patient has severe renal failure (5)[B].
- Treat as outpatient, if possible (5)[B].
- Initiate warfarin together with LMWH on the first treatment day, and discontinue LMWH after a minimum of 5 days and two consecutive INRs >2 (5)[A].

---

P.863

- For pregnant women with no prior history of VTE, we suggest antepartum and postpartum clinical vigilance. Postpartum prophylaxis is reserved for patients with positive family history only; in that case, we suggest prophylactic- or intermediate-dose LMWH for 6 weeks (1)[C], (5).

# MEDICATION

## First Line

- Low-molecular-weight heparin (LMWH) (2)[A] initially for a minimum of 5 days and two consecutive INRs between 2 and 3, at which time it can be stopped
  - Enoxaparin (Lovenox) 1 mg/kg SC BID:
    - Alternatively, 1.5 mg/kg/day SC
  - Tinzaparin (Innohep) 175 anti-Xa IU/kg/day SC
  - Dalteparin (Fragmin) 200 IU/kg/day
- Factor Xa Inhibitor
  - Fondaparinux (Arixtra) <50 kg: 5 mg/day SC; 50 to 100 kg: 7.5 mg/day SC; >100 kg: 10 mg/day SC; contraindicated if CrCl <30 mL/min
- Oral anticoagulant: warfarin (Coumadin): 5 mg/day PO then adjusted to an INR of 2 to 3 for at least 6 months (5)[A]
- Novel oral anticoagulants (NOACs) (6):
  - Dabigatran 150 mg po BID (after 5 to 10 days of parenteral anticoagulation)
  - Rivaroxaban 15 mg po BID for 21 days then 20 mg PO QID
  - Apixaban 10 mg PO BID for 7 days then 5 mg PO BID
  - Edoxaban 60 mg PO QID (after 5 to 10 days of parenteral anticoagulation)
- Contraindications
  - Active bleeding precludes anticoagulation; risk of bleeding is a relative contraindication to long-term anticoagulation.
  - Warfarin is contraindicated in patients with a prior history of warfarin-induced skin necrosis.
- Precautions
  - Observe patient for signs of embolization, further thrombosis, or bleeding.
  - Avoid IM injections.
  - Periodically, check stool and urine for occult blood; monitor CBC, including platelets.
  - Heparin: thrombocytopenia and/or paradoxical thrombosis with thrombocytopenia
  - Warfarin: necrotic skin lesions (typically breasts, thighs, and buttocks)

- LMWH: Adjust dose in renal insufficiency.
- Significant possible interactions
  - Agents that intensify the response to oral anticoagulants: alcohol, allopurinol, amiodarone, anabolic steroids, androgens, many antimicrobials, cimetidine, chloral hydrate, disulfiram, all NSAIDs, sulfapyrazone, tamoxifen, thyroid hormone, vitamin E, ranitidine, salicylates, acetaminophen
  - Agents that diminish the response to oral anticoagulants: aminoglutethimide, antacids, barbiturates, carbamazepine, cholestyramine, diuretics, griseofulvin, rifampin, oral contraceptives

## *Second Line*

Heparin 80 mg/kg IV bolus, followed by 18 mg/kg/hr; adjust dose depending on aPTT:

- In patients requiring large daily doses of heparin, measure an anti-Xa level for dose guidance.
- Alternatively, in outpatients, unfractionated heparin can be given at 333 units/kg then 250 units/kg SC, without monitoring (5)[C].
- It does not alter plasma protein S concentration.

## *ISSUES FOR REFERRAL*

- Patients with suspected protein S deficiency should be seen by a hematologist.
- Screening and prophylactic treatment of asymptomatic family members is not justified (7).

## *SURGERY/OTHER PROCEDURES*

- Anticoagulation must be held for surgical interventions.
- For most patients with DVT, recommendations are against routine use of vena cava filter in addition to anticoagulation; IVC filter is only recommended in case of contraindication to anticoagulation (5)[A].

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Life-threatening VT
- Significant bleeding while on anticoagulant therapy

## *Nursing*

Look for signs of bleeding while on anticoagulation therapy.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- Warfarin requires periodic (monthly after initial stabilization) monitoring of the INR.
- Periodic measurement of INR to maintain a range of 2 to 3.
- LMWH is the treatment of choice in pregnancy. Periodic monitoring with anti-Xa levels is recommended in some cases, such as overweight and borderline renal failure.

#### *DIET*

Unrestricted

### PATIENT EDUCATION

- Patients should be educated about use of oral anticoagulant therapy if taking such.
- Patients undergoing warfarin therapy should avoid drinking alcohol on a daily basis.
- Avoid NSAIDs while on warfarin.

### PROGNOSIS

- Persons with protein S deficiency have normal lifespan.
- By age 45 years, 50% of the people heterozygous for protein S deficiency will have VT; half will be spontaneous.

### COMPLICATIONS

Recurrent thrombosis (requires indefinite anticoagulation)

## Codes

**&NA;**

### ICD10

D68.59 Other primary thrombophilia

## Clinical Pearls

**&NA;**

- Asymptomatic patients with protein S deficiency do not require prophylactic anticoagulation because the risk of thrombosis is low; asymptomatic patients do not require anticoagulation (6).
- Patients with protein S deficiency and DVT should be anticoagulated for at least 6 months, especially if first episode.

# Proteinuria

Andrew S. Allegretti, MD

## BASICS

### DESCRIPTION

Urinary protein excretion of >150 mg/day

- Nephrotic-range proteinuria: urinary protein excretion of >3.5 g/day; also called *heavy proteinuria*
- Three pathologic types:
  - Glomerular proteinuria: increased permeability of proteins across glomerular capillary membrane
  - Tubular proteinuria: decreased proximal tubular reabsorption of proteins
  - Overflow proteinuria: increased production of low-molecular-weight proteins

### Pediatric Considerations

- Proteinuria: Normal is daily excretion of up to 100 mg/m<sup>2</sup> (body surface area).
- Nephrotic-range proteinuria: daily excretion of >1,000 mg/m<sup>2</sup> (body surface area)

### Pregnancy Considerations

- Proteinuria in pregnancy beyond 20 weeks' gestation is a hallmark of preeclampsia/eclampsia and demands further workup.
- Proteinuria in pregnancy before 20 weeks' gestation is suggestive of underlying renal disease.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Glomerular proteinuria: increased filtration/larger proteins (albumin) due to the following:
  - Increased size of glomerular basement membrane pores and
  - Loss of proteoglycan negative charge barrier
- Tubular proteinuria: Tubulointerstitial disease prevents proximal tubular reabsorption of

smaller proteins (&#x2013;microglobulin, immunoglobulin [Ig] light chains, retinol-binding protein, amino acids).

- Overflow proteinuria: proximal tubular reabsorption overwhelmed by increased production of smaller proteins
- Glomerular proteinuria
  - Primary glomerulonephropathy
    - Minimal-change disease
    - Idiopathic/primary membranous glomerulonephritis
    - Focal segmental glomerulonephritis
    - Membranoproliferative glomerulonephritis
    - IgA nephropathy
  - Secondary glomerulonephropathy
    - Diabetic nephropathy
    - Autoimmune/collagen vascular disorders (e.g., lupus nephritis, Goodpasture syndrome)
    - Amyloidosis
    - Preeclampsia
    - Infection (HIV, hepatitis B and C, poststreptococcal, endocarditis, syphilis, malaria)
    - Malignancy (GI, lung, lymphoma)
    - Renal transplant rejection
    - Structural (reflux nephropathy, polycystic kidney disease)
    - Drug-induced (NSAIDs, penicillamine, lithium, heavy metals, gold, heroin)
- Tubular proteinuria
  - Hypertensive nephrosclerosis
  - Tubulointerstitial disease (uric acid nephropathy, hypersensitivity, interstitial nephritis, Fanconi syndrome, heavy metals, sickle cell disease, NSAIDs, antibiotics)
  - Acute tubular necrosis
- Overflow proteinuria
  - Multiple myeloma (light chains; also tubulotoxic)

- Hemoglobinuria
  - Myoglobinuria (in rhabdomyolysis)
  - Lysozyme (in acute monocytic leukemia)
- Benign proteinuria
  - Functional (fever, exercise, cold exposure, stress, CHF)
  - Idiopathic transient
  - Orthostasis (postural)

## ***RISK FACTORS***

- Hypertension
- Diabetes
- Obesity
- Strenuous exercise
- CHF
- UTI
- Fever

## ***Genetics***

No known genetic pattern

## ***GENERAL PREVENTION***

Control of weight, BP, and blood glucose reduces the risk of proteinuria.

## ***COMMONLY ASSOCIATED CONDITIONS***

- Hypertension (common)
- Diabetes mellitus (common)
- Preeclampsia (common)
- Multiple myeloma (rare)

**DIAGNOSIS**

## **HISTORY**

- Frothy/foamy urine
- Change in urine output
- Blood- or cola-colored urine
- Recent weight change
- Swelling
- Rule out systemic illness: diabetes, heart failure, autoimmune, poststreptococcal infection

## **PHYSICAL EXAM**

- BP
- Weight
- Peripheral edema
- Periorbital/facial edema
- Ascites
- Palpation of kidneys
- Check lungs, heart for signs of CHF

## **DIFFERENTIAL DIAGNOSIS**

Includes all causes listed under Etiology and Pathophysiology

## **DIAGNOSTIC TESTS & INTERPRETATION**

Screening for proteinuria is not cost-effective unless directed at groups with hypertension/diabetes, older persons, and so forth.

### ***Initial Tests (lab, imaging)***

- Urinalysis (UA) quantitatively estimates proteinuria:
  - Only sensitive to albumin; will not detect smaller proteins of overflow/tubular etiologies
  - False-positive finding if urine pH >7, highly concentrated (specific gravity [SG] >1.015), gross hematuria, mucus, semen, leukocytes, iodinated contrast agents, penicillin analogues, sulfonamide metabolites
  - False-negative finding if urine is dilute (SG 1.005), albumin excretion <20 to 30 mg/dL, protein is nonalbumin

- Sensitivity, 32-46%; specificity, 97-100%
- Also can perform sulfosalicylic acid test to detect nonalbumin protein
- If UA positive, perform urine microscopy. Refer to nephrologist if positive for signs of glomerular disease.
- If UA shows trace to 2+ protein, rule out transient proteinuria with repeat UA at another visit:
  - More common than persistent proteinuria
  - Causes include exercise, fever, CHF, UTI, and cold exposure
  - Reassure patient that transient proteinuria is benign and requires no further workup.
- If initial UA shows 3+ to 4+ protein or repeat UA is positive, measure creatinine clearance and quantify proteinuria with 24-hour urine collection (gold standard) or spot urine protein-to-creatinine (P/C) ratio (acceptable practice) (1)[A]:
  - Numerical P/C ratios correlate with total protein excreted in grams per day (i.e., ratio of 0.2 correlates with 0.2 g during a 24-hour collection).
  - Patients age <30 years with 24-hour urine excretion of <2 g/day and normal creatinine clearance should be tested for orthostatic proteinuria:
    - Benign condition is present in 2-5% of adolescents.
    - Diagnosed with a normal urine P/C ratio in first morning void and an elevated urine P/C ratio in a second specimen taken after standing for several hours
- If protein excretion >2 g/day, consider nephrology referral and begin workup for systemic/renal disease.
- Patients with persistent proteinuria not explained by orthostatic changes should undergo renal ultrasound to rule out structural abnormalities (e.g., reflux nephropathy, polycystic kidney).

### *Follow-Up Tests & Special Considerations*

Renal/systemic disease workup can include the following:

- CBC, ferritin, ESR, serum iron
- Electrolytes, LFTs
- Lipid profile (ideally, fasting)
- Prothrombin time/international normalized ratio
- Anti-phospholipase A2 receptor antibody: positive in ÷70% of primary membranous nephropathy

- Antinuclear antibodies: elevated in lupus
- Antistreptolysin O titer: elevated after streptococcal glomerulonephritis

- Complement C3/C4: low in most glomerulonephritis
- HIV, syphilis, and hepatitis serologies: all associated with glomerular proteinuria
- Serum and urine protein electrophoresis: abnormal in multiple myeloma
- Blood glucose: elevated in diabetes
- All patients with diabetes should be screened for microalbuminuria.
- Patients with nephrotic-range proteinuria are at increased risk for hypercholesterolemia and thromboembolic events ( $\div$ 25% of adult patients) with highest risk in membranous nephropathy. Optimal duration of prophylactic anticoagulation is unknown but may extend for the duration of the nephrotic state (2).
- Proteinuric pregnant patients beyond 20 weeks' gestation should be examined for other signs/symptoms of preeclampsia (e.g., hypertension, thrombocytopenia, elevated liver transaminases).

## TREATMENT

- BP goals for both diabetic and nondiabetic adults is  $\leq$ 140/90 mm Hg (3)[C].
- Proteinuria goal is  $<$ 0.5 g/day (4)[A].

## GENERAL MEASURES

- Limit protein intake to 0.8 g/kg/day in adults with DM or without DM and glomerular filtration rate (GFR)  $<$ 30 mL/min/1.73 m<sup>2</sup>. Soy protein may be renoprotective. Monitor protein intake with 24-hour urine urea excretion (4)[A].
- Limit sodium chloride intake to  $<$ 2 g/day to optimize antiproteinuric medications (3)[B]. Effect on BP is further protective (4)[A].
- Limit fluid intake for urine output goal of  $<$ 2 L/day. Larger urine volumes are associated with increased proteinuria and later GFR decline (4)[B].
- Smoking cessation: Smoking is associated with increased proteinuria and faster kidney disease progression (4)[B].
- Encourage supine posture (up to 50% reduction vs. upright) (4)[B].
- Discourage severe exertion (4)[B].

- Encourage weight loss (4)[B].

## *MEDICATION*

### *First Line*

- ACE inhibitors: first choice; use maximally tolerated doses; use even if normotensive (4)[A]
- Angiotensin receptor blockers (ARBs): proven antiproteinuric and renoprotective; ARBs are first choice if ACE inhibitors are not tolerated (4)[A].
- Combination ACE inhibitor and ARB should not be used. Although shown to reduce proteinuria, combination does not reduce poor CV outcomes and does increase risk of adverse drug reactions (5)[A].

### *Second Line*

- *&bgr*;-Blockers: antiproteinuric and cardioprotective (4)[A]
- Dihydropyridine calcium channel blockers (DHCCBs): should be avoided unless needed for BP control; not antiproteinuric (4)[A]
- Non-DHCCB: antiproteinuric, may be renoprotective (4)[B]
- Aldosterone antagonists: antiproteinuric independent of BP control (4)[B]
- NSAIDs: antiproteinuric, but also nephrotoxic; generally should be avoided (4)[C]

## *ISSUES FOR REFERRAL*

Consider nephrology referral for possible renal biopsy if

- Impaired creatinine clearance
- Nephrotic-range proteinuria
- Unclear etiology of non-nephrotic-range proteinuria
- Diabetics with microalbuminuria

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Corticosteroids: No proven benefit in mortality or need for renal replacement in adults with nephrotic syndrome, although steroids are recommended in some patients who do not respond to conservative treatment. Classically, children with nephrotic syndrome respond better than adults, especially those with minimal-change disease (6)[A].
- Estrogen/progesterone replacement: may be renoprotective in premenopausal women but

should be avoided in postmenopausal women (4)[B]

- Antioxidant therapy: may be antiproteinuric in diabetic nephropathy (4)[C]
- Sodium bicarbonate: not antiproteinuric but may block tubular injury caused by proteinuria; correcting metabolic acidosis may decrease protein catabolism (4)[C].
- Avoid excessive caffeine consumption: antiproteinuric in diabetic rat models (4)[C]
- Avoid iron overload (4)[C].
- Pentoxifylline: prevents progression of renal disease by unclear mechanisms (4)[C]
- Mycophenolate mofetil: antiproteinuric and renoprotective in animal models (4)[C]

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

All patients with persistent proteinuria should be followed with serial BP checks, UA, and renal function tests in the outpatient setting. Intervals depend on underlying etiology.

### *PROGNOSIS*

- Transient and orthostatic proteinuria are benign conditions that do not convey a poor prognosis.
- Clinical significance of persistent proteinuria varies greatly and depends on underlying etiology.
- Degree of proteinuria is associated with disease progression in chronic kidney disease.
- Independent of GFR, higher levels of proteinuria likely convey an increased risk of mortality, myocardial infarction, and progression to kidney failure (7).

### **COMPLICATIONS**

- Progression to chronic renal failure and the need for dialysis/renal transplant
- Hypercholesterolemia
- Hypercoagulable state

## Codes

**&NA;**

### ICD10

- R80.9 Proteinuria, unspecified
- R80.2 Orthostatic proteinuria, unspecified
- R80.1 Persistent proteinuria, unspecified

## Clinical Pearls

**&NA;**

- Transient and orthostatic proteinuria are benign conditions that do not convey a poor prognosis.

- Proteinuria  $>2$  g/day likely represents glomerular malfunction and warrants a nephrology consultation.
- Clinical course varies greatly but, in general, the degree of proteinuria correlates with kidney disease progression.
- First-line therapy for persistent proteinuric patients is a high-dose ACE inhibitor.

# Prothrombin 20210 (Mutation)

Dalia Hammoud, MD

Elie Chalhoub, MD

Maissaa Janbain, MD

## BASICS

### DESCRIPTION

- Prothrombin 20210 mutation is the second most common inherited risk factor for venous thromboembolism after factor V Leiden mutation.
- Polymorphism (replacement of G by A) in the 3' untranslated end of the prothrombin gene causes increased translation, resulting in elevated synthesis and secretion of prothrombin. This leads to a 2.8-fold increased risk for venous thrombosis.
- Heterozygous carriers have 30% higher plasma prothrombin levels than normal
- System(s) affected: cardiovascular; hemic/lymphatic/immunologic; nervous; pulmonary; reproductive
- Synonym(s): prothrombin G20210A mutation; prothrombin G20210 gene polymorphism; prothrombin gene mutation; FII A<sup>20210</sup> mutation

### EPIDEMIOLOGY

- Found largely in Caucasian population. Found in 2-5% of European and Middle Eastern population, but rarely in nonwhites. Found in 4-8% of persons with venous thromboembolism and in up to 18% of patients with recurrent thrombosis.
- Predominant age: Mean age of first thrombosis is in the 2nd decade of life.
- Predominant gender: male = female

### Prevalence

3-5% of the population

### ETIOLOGY AND PATHOPHYSIOLOGY

- Replacement of G for A in the 3' untranslated region of the prothrombin gene resulting in

relatively higher plasma prothrombin activity, leading to increased risk for venous thrombosis.

- Prothrombin Yukuhashi (Arg596Leu) was described in a Japanese thrombophilic family. The mutant prothrombin had moderately lower, but adequate, activity than wild-type prothrombin. The thrombin molecule generated is resistant to inactivation by antithrombin, thereby conferring an increased susceptibility to thrombosis.
- Gene mutation

## *Genetics*

Autosomal dominant

## **RISK FACTORS**

- Patients with prothrombin 20210 and another prothrombotic state, such as factor V Leiden, have increased rates of thrombosis (1).
- The risk of venous thrombosis in patients with prothrombin 20210 mutation increases when added to the use of oral contraceptives, pregnancy, and the use of hormone replacement therapy as well as any status associated with prolonged immobilization (1).

## *Pregnancy Considerations*

- Increased thrombotic risk in patients with prothrombin 20210.
- A new mutation C20209T has been described recently in women with recurrent pregnancy loss; the clinical and biochemical implications of this mutation are not fully understood yet (2).

## **GENERAL PREVENTION**

Patients with prothrombin 20210 without thrombosis do not require prophylactic anticoagulation (3)[A], except for pregnant women with family history of venous thromboembolism, who require antepartum and 6-week postpartum prophylaxis with LMWH (4)[B].

## **COMMONLY ASSOCIATED CONDITIONS**

Venous thromboembolism

## **DIAGNOSIS**

### **HISTORY**

- Previous thrombosis
- Family history of thrombosis

## *PHYSICAL EXAM*

Arterial thrombosis is rare in adults with prothrombin 20210 gene mutation.

## *DIFFERENTIAL DIAGNOSIS*

- Factor V Leiden mutation
- Protein C deficiency
- Protein S deficiency
- Antithrombin deficiency
- Other causes of activated protein C resistance (e.g., antiphospholipid antibodies)
- Dysfibrinogenemia
- Dysplasminogenemia
- Homocystinemia
- Elevated factor VIII levels

## *DIAGNOSTIC TESTS & INTERPRETATION*

Test patients with thrombosis at age <50 years, history of recurrent idiopathic thrombosis, those with thrombosis in unusual locations, or those with strong family history.

### *Initial Tests (lab, imaging)*

- For evaluation of a new clot in patients at risk: CBC with peripheral smear, PT/INR, aPTT, thrombin time, lupus anticoagulant, antiphospholipid antibodies, factor VIII, anticardiolipin antibody, anti-B2 glycoprotein I antibody, activated protein C resistance, protein S antigen and resistance, antithrombin III assay, fibrinogen, factor V Leiden, prothrombin G20210A, homocysteine
- DNA analysis for mutation
- Testing is reliable during acute thrombosis and on any kind of anticoagulation, as is gene analysis (4).
- As appropriate for suspected site of thrombosis: US, CT scan, and V/Q scan

### *Follow-Up Tests & Special Considerations*

Although prothrombin levels are elevated, this is not a sensitive test to make the diagnosis.

## Diagnostic Procedures/Other

MR angiography (MRA), venography, or arteriography to detect thrombosis

## Test Interpretation

Venous thrombus

## TREATMENT

For acute thrombosis

## GENERAL MEASURES

- Patients with prothrombin 20210 mutation and a first thrombosis should receive anticoagulation medication initially with heparin or LMWH (1)[A].
- Treatment with LMWH is recommended over unfractionated heparin, unless the patient has severe renal failure (3)[A].
- Treat as outpatient, if possible (3)[B].
- Initiate warfarin on day 1 or 2 of LMWH therapy; discontinue LMWH after minimum of 5 days and 2 consecutive INRs >2 (3)[A].
- Patients should be maintained on warfarin with an INR of 2 to 3 for at least 3 months (4)[A].
- Recurrent thrombosis requires indefinite anticoagulation (1)[B].

## MEDICATION

### First Line

- Low-molecular-weight heparin (LMWH) (3)[A]
  - Enoxaparin (Lovenox): 1 mg/kg SC BID; tinzaparin (Innohep): 175 anti-Xa IU/kg SC daily; dalteparin (Fragmin): 200 IU/kg SC daily
  - Initiate warfarin on day 1 or 2 of LMWH therapy; continue LMWH for a minimum of 5 days and 2 consecutive INRs >2
  - Fondaparinux (Arixtra): <50 kg: 5 mg SC daily; 50 to 100 kg: 7.5 mg SC daily; >100 kg: 10 mg SC daily
- Oral anticoagulant
  - Warfarin (Coumadin) 5 mg PO daily; then adjusted to an INR of 2 to 3 (4)

- Contraindications
  - Active bleeding precludes anticoagulation (3)[A].
  - Risk of bleeding is a relative contraindication to long-term anticoagulation (3)[A].
  - Warfarin is contraindicated in patients with history of warfarin skin necrosis (3)[A].
  - Fondaparinux: severe renal impairment (CrCl <30 mL/min)
- Precautions
  - Observe patient for signs of embolization, further thrombosis, or bleeding.
  - Avoid IM injections. Periodically check stool and urine for occult blood; monitor CBCs, including platelets.
  - Heparins: thrombocytopenia
  - Warfarin: necrotic skin lesions (typically breasts, thighs, or buttocks)
  - LMWH: Adjust dosage in renal insufficiency.
- Significant possible interactions
  - Agents that intensify the response to oral anticoagulants: alcohol, allopurinol, amiodarone, anabolic steroids, androgens, many antimicrobials, cimetidine, chloral hydrate, disulfiram, all NSAIDs, sulfapyrazone, tamoxifen, thyroid hormone, vitamin E, ranitidine, salicylates, acetaminophen
  - Agents that diminish the response to anticoagulants: aminoglutethimide, antacids, barbiturates, carbamazepine, cholestyramine, diuretics, griseofulvin, rifampin, oral contraceptives

## *Second Line*

- Heparin 80 mg/kg IV bolus followed by 18 g/kg/hr continuous infusion
- Adjust dose, depending on aPTT.
- In patients requiring large daily doses of heparin, measure an anti-Xa level for dose guidance.
- Alternatively, unfractionated heparin can be given for outpatients at 333 U/kg then 250 U/kg SC (4)[A].

## *ISSUES FOR REFERRAL*

- Recurrent thrombosis on anticoagulation

- Difficulty anticoagulating
- Genetic counseling

## ***SURGERY/OTHER PROCEDURES***

- Anticoagulation must be held for surgical interventions.
- For most patients with deep venous thrombosis (DVT), recommendations are against routine use of vena cava filter in addition to anticoagulation, except in case with contraindication to anticoagulation (4)[A].
- Thrombectomy may be necessary in some cases.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Complicated thrombosis, such as pulmonary embolus; heparin

### ***Discharge Criteria***

Stable on anticoagulation

## **ONGOING CARE**

Compression stockings for prevention

## ***FOLLOW-UP RECOMMENDATIONS***

### ***Patient Monitoring***

- Warfarin use requires periodic (monthly after initial stabilization) INR measurements, with a goal of 2 to 3 (3)[A].
- Heterozygous prothrombin 20210 mutations increase the risk for recurrent venous thromboembolism (VTE) only slightly once anticoagulation is stopped and should have the same length of anticoagulation as in someone without the mutation.

## ***DIET***

- No restrictions
- Food rich in vitamin K may interfere with warfarin anticoagulation.

## ***PATIENT EDUCATION***

- Patients should be educated about:
  - Use of oral anticoagulant therapy.
  - Avoidance of NSAIDs while on warfarin
- The role of family screening is unclear, as most patients with this mutation do not have thrombosis. In a patient with a family history of prothrombin 20210, consider screening during pregnancy or if considering oral contraceptive use.

## PROGNOSIS

- When compared with normal individuals, persons with prothrombin 20210 have normal lifespan.
- Carriage of the PT20210 mutation has been linked to an increased rate of liver fibrosis in HCV patients (5).

## COMPLICATIONS

- Recurrent thrombosis
- Bleeding on anticoagulation

## Codes

**&NA;**

### ICD10

D68.52 Prothrombin gene mutation

## Clinical Pearls

**&NA;**

- Prothrombin 20210 mutation is the second most common inherited risk factor for VTE after factor V Leiden mutation.
- Asymptomatic patients with prothrombin 20210 mutation do not need anticoagulation.
- Testing for the prothrombin G20210 mutation may be done while the patient is anticoagulated, as it is a genetic assay.
- For pregnant women homozygous for factor V Leiden, or heterozygous for factor V and prothrombin G20210 mutation, but no prior history of VTE, postpartum prophylaxis with prophylactic or intermediate-dose LMWH or vitamin K antagonists with target INR 2 to 3 for 6 weeks is recommended. Antepartum prophylaxis is added if there is positive family of VTE.

# Pruritus Ani

Jessica Davis, MD

Pia Prakash, MD

Marie L. Borum, MD, EdD, MPH

## BASICS

### DESCRIPTION

- Intense, unpleasant anal and perianal itching and/or burning
- Usually acute
- Can be classified as idiopathic (primary) pruritus ani (50-90%) or secondary to anorectal pathology (1)

### EPIDEMIOLOGY

#### *Incidence*

- 1-5% of the general population (1)
- Predominant age: 30 to 60 years (1)
- Predominant sex: male > female (4:1) (1)

#### *Prevalence*

Difficult to estimate as often unreported, one study found present in 2.4% of patients visiting PCPs (2).

### ETIOLOGY AND PATHOPHYSIOLOGY

- Perianal itching (primary or secondary) incites itch-scratch cycle that may self-perpetuate, as resulting lichenification worsens pruritus.
- Etiologies of primary pruritus ani
  - Poor anal hygiene
  - Loose or leaking stool that makes hygiene difficult—of note, interestingly, patients with abdominal ostomy bags typically do not complain of pruritus (1).

- Internal sphincter laxity
- Idiopathic
- Etiologies of secondary pruritus ani
  - Inflammatory dermatologic disorders
    - Allergic contact dermatitis (soaps, perfumes, or dyes in toilet paper, topical anesthetics, oral antibiotics)
    - Psoriasis: Lesions tend to be poorly demarcated, pale, and nonscaling.
    - Atopic dermatitis ± lichen simplex chronicus: Patients are likely to have asthma and/or eczema.
    - Eczema from dietary elements (citrus, vitamin C supplements, milk products, coffee, tea, cola, chocolate, beer, wine)
    - Seborrheic dermatitis
    - Lichen planus: may be seen in patients with ulcerative colitis and myasthenia gravis
  - Colorectal and anal pathology: rectal prolapse, hemorrhoids, fissures or fistulas, chronic diarrhea/constipation, papillomas, condyloma, polyps, cancer
  - Malignancies: uncommon, but pruritus ani may be presenting symptom of Bowen or Paget disease
  - Infectious etiologies: dermatophytes (*Tinea*), bacteria (*Staphylococcus aureus*, &agr;-hemolytic *Streptococcus*, *Corynebacterium minutissimum* [Erythrasma], gonorrhea, syphilis), viruses (herpes simplex virus [HSV], human papillomavirus [HPV], molluscum), parasites (pinworms, rarely scabies, or pediculosis)
  - Mechanical factors: vigorous cleaning and scrubbing, tight-fitting clothes, synthetic undergarments
  - Systemic diseases: diabetes mellitus (most common), chronic liver disease, renal failure, leukemia or lymphoma, hyperthyroidism, anemia
  - Chemical irritants: chemotherapy, diarrhea (often from antibiotic use)
  - Psychogenic factors: anxiety-itch-anxiety cycle

## **RISK FACTORS**

- Obesity
- Excess perianal hair growth, excessive perspiration

Underlying anorectal pathology

- Underlying anxiety disorder
- Caffeine intake has been correlated with symptoms.

## GENERAL PREVENTION

- Good perianal hygiene
- Avoid mechanical irritation of skin (vigorous cleaning or rubbing, harsh soaps or perfumed products, excessive cleansing with dry toilet paper or baby wipes, scratching with fingernails, or tight/synthetic undergarments). Minimize moisture in perianal area (absorbent cotton in anal cleft may help keep area dry).
- Avoid laxative use (loose stool is an irritant).

## COMMONLY ASSOCIATED CONDITIONS

See earlier listing of conditions causing perianal irritation.

## DIAGNOSIS

### HISTORY

- Patient presents with complaint of anal and/or perianal itching, burning, or excoriations.
- Inquire about:
  - Melena or hematochezia
  - Frequency of cleansing and products used on affected area
  - Change in bowel habits
  - Recent antibiotic use
  - Medical history (diabetes in particular)
  - Skin disorders (psoriasis, eczema)
  - Rectal or vaginal discharge
  - Dietary history: focus on the "C"s: Caffeine, coffee, cola, chocolate, citrus, calcium (dairy) (3)
  - Family history of colorectal cancer
  - Anal receptive intercourse
  - Change in toiletry products
  - Household members with itching (possible pinworms)

- Clothing preference (tight, synthetic) (1)

## PHYSICAL EXAM

- Perianal inspection for erythema, hemorrhoids, anal fissures, maceration, lichenification, rashes, warts, excoriations, neoplasia
- Digital rectal exam to check for masses and to evaluate internal sphincter tone, Valsalva to evaluate for prolapse
- Anoscopy to evaluate for hemorrhoids, fissures, other internal lesions
- Classification based on gross appearance
  - Stage 1: erythema, inflamed appearance
  - Stage 2: lichenification
  - Stage 3: lichenification, coarse skin, potential fissures or ulcerations (1)[C]

## DIFFERENTIAL DIAGNOSIS

- ÒITCHEÓ acronym (4)
  - **I**nfection: pinworms, dermatophytes, grampositive bacteria, HSV, gonorrhea, chlamydia, syphilis, HPV, erythrasma, scabies
  - **T**opical irritant: detergents, garments, deodorants, perfumes, stool leakage
  - **C**utaneous/cancer/colorectal: eczema, psoriasis, lichen planus, lichen sclerosus, seborrheic dermatosis, squamous cell cancer, extramammary Paget disease, Bowen disease, melanoma, fistula, fissure, prolapse, hemorrhoids, colorectal cancer
  - **H**ypersensitivity: foods (the ÒC'sÓ above), medications (colchicine, quinidine, mineral oil)
  - **e**Systemic: diabetes, uremia, cholestasis, hematologic malignancy

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

Depending on patient's history and exam, consider the following:

- Pinworm tape test; stool for ova and parasites
- CBC, comprehensive metabolic panel, A1c, thyroid studies to identify underlying systemic disease
- Wood lamp examination will show coral-red fluorescence in erythrasma (1).

- Skin scraping with potassium hydroxide (KOH) prep for dermatophytes or candidiasis (as etiology or as superinfection) and mineral oil prep for scabies
- Perianal skin culture (bacterial superinfection)
- Hemocult testing of stool

### *Pediatric Considerations*

Pinworms are common in children.

### *Follow-Up Tests & Special Considerations*

Anal DNA polymerase chain reaction (PCR) probe for gonorrhea and chlamydia and anal Pap smear for HPV if receptive anal intercourse

### *Diagnostic Procedures/Other*

- Biopsy suspicious lesions (e.g., lichenification, ulcerated epithelium, refractory cases) to exclude neoplasia
- Consider colonoscopy if history, exam, or testing suggests colorectal pathology (family history of colorectal disease, especially if age >40 years, weight loss, rectal bleeding, change in bowel habits).

### *Geriatric Considerations*

- Stool incontinence may be a predisposing factor.
- Consider systemic disease.
- Higher likelihood of colorectal pathology

## **TREATMENT**

### *GENERAL MEASURES*

- Educate patients regarding proper anal hygiene and avoidance of chemical and mechanical irritants (1).
- High-fiber diet and/or bowel regimen to maintain regular bowel movements (1)
- Avoid tight-fitting clothing and use cotton undergarments.
- Talcum powder or cornstarch if excess moisture (1)
- Wear cotton gloves at night to control nocturnal scratching (1).

# MEDICATION

## First Line

- Treat underlying infections: fungal or dermatophyte infection with topical imidazoles, bacterial infection with topical antibacterials.
- Break itch-scratch cycle with low-potency steroid cream such as hydrocortisone 1% ointment applied sparingly up to 4 times daily (1)[A]. Discontinue when itching subsides. Recommended not to use >12 weeks due to risk of skin atrophy.
- If no response with low-potency steroid, consider high-potency steroid cream.
- Antihistamines may be useful until local measures take effect, particularly sedating antihistamines, which will reduce nighttime itching.

P.869

- Some experts suggest a trial of tricyclic antidepressants to reduce nighttime scratching.
- Zinc oxide can be used after completing steroid course for barrier protection (3)[C]; petroleum jelly is another barrier treatment.
- Although trial data are mixed, topical capsaicin cream may be used in combination with steroid cream if refractory itch or hypersensitized skin (1,5)[A].
- A small RCT showed benefit with 0.1% tacrolimus ointment; this may be a good choice in patients with skin thinning at risk for atrophy from prolonged steroid use (6)[C].
- Several small case series have shown symptomatic benefit with methylene blue injection; this may be an additional option for patients with refractory symptoms (7)[C].

## Second Line

Radiation may be used to destroy nerve endings (create permanent anesthesia) in intractable cases. This is almost never indicated but is very effective.

## ISSUES FOR REFERRAL

- Intractable pruritus: Consider referral to gastroenterology (for colonoscopy) or dermatology (for additional treatment, possibly injections). Refractory or persistent symptoms should signal the possibility of underlying neoplasia, as pruritus ani of long duration is associated with a greater likelihood of colorectal pathology.
- If risks or red flags for colon cancer are present, refer for colonoscopy.

## SURGERY/OTHER PROCEDURES

None unless malignancy identified

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

See patient in 2 weeks if not improving. Check for persistent lichenification. With refractory pruritus or lichenification that does not resolve, consider underlying malignancy.

### *DIET*

- Trial elimination of foods and beverages known or suspected to exacerbate symptoms: coffee, tea, chocolate, beer, cola, vitamin C tablets in excessive doses, citrus fruits, tomatoes, or spices
- Eliminate foods or drugs contributing to loose bowel movements. Add fiber supplementation to bulk stools and prevent fecal leakage in patients who have fecal incontinence or partially formed stools.

### *PATIENT EDUCATION*

- Review proper anal hygiene:
  - Resist overuse of soap and rubbing.
  - Avoid toiletry products with irritating perfumes and dyes.
  - Avoid use of ointments to the area, including witch hazel.
  - Wear loose, light cotton clothing.
  - If moisture is a problem, unmedicated talcum powder or cornstarch to keep the area dry.
  - Cleanse perianal area after bowel movements with water-moistened cotton.
  - Dry area after bathing by patting with a soft towel or by using a hair dryer (1).
- Avoid medications that cause diarrhea or constipation.
- Avoid foods implicated in pruritus ani: caffeine, cola, chocolate, citrus, tomatoes, tea, beer/wine (3)[C].
- Use barrier protection if engaging in anal intercourse.
- If unable to completely empty rectum with defecation, use small plain-water enema (infant bulb syringe) after each bowel movement to prevent soiling and irritation.

## PROGNOSIS

- Conservative treatment is successful in ÷90% of patients.
- Idiopathic pruritus ani often is chronic, waxing and waning. Regardless of etiology, however, pruritus ani may be persistent and recurrent.

## COMPLICATIONS

- Bacterial superinfection at site of excoriations and potential abscess formation or penetrating infection via self-inoculation with colonic pathogens
- Lichenification

## See Also

## &NA;

Pinworms; Pruritus Vulvae

## Codes

## &NA;

## ICD10

L29.0 Pruritus ani

# Clinical Pearls

## &NA;

- Pruritus ani is characterized by intense anal and perianal itching and/or burning.
- Usually idiopathic or related to skin irritation with subsequent scratch-itch-scratch cycle
- Conservative treatment with good perianal hygiene and reassurance are successful in 90% of patients.
- Consider trial of dietary elimination of citrus, vitamin C supplements, calcium, caffeine, coffee, cola, chocolate.
- Rule out infection in immunosuppressed patients.
- Consider underlying malignancy if refractory

# Pruritus Vulvae

Maeve K. Hopkins, MA, MD

Michael P. Hopkins, MD, MEd

## BASICS

### DESCRIPTION

- Pruritus vulvae is a symptom, as well as a primary diagnosis:
  - The symptom may indicate an underlying pathologic process.
  - Only when no underlying disease is identified may this be used as a primary diagnosis.
- Pruritus vulvae as a primary diagnosis may also be more appropriately documented as vulvodynia (see "Vulvodynia" topic) or burning vulva syndrome.

### EPIDEMIOLOGY

Symptoms may occur at any age during a woman's lifetime.

- Young girls most commonly have infectious or hygiene etiology.
- The primary diagnosis is more common in postmenopausal women.

### Incidence

The exact incidence is unknown, although most women complain of vulvar pruritus at some point in their lifetime.

### ETIOLOGY AND PATHOPHYSIOLOGY

Vulvar tissue is more permeable than exposed skin due to differences in structure, occlusion, hydration, and susceptibility to friction. It is particularly vulnerable to irritants (1)

- Perfumes
- Soaps
- Laundry detergent
- Douches
- Toilet paper

- Sanitary napkins

## **RISK FACTORS**

- High-risk sexual behavior
- Immunosuppression
- Obesity

## **GENERAL PREVENTION**

- Attention should be paid to personal hygiene and avoidance of possible environmental factors.
- Tight-fitting clothing should be avoided.
- Only cotton underwear should be worn.

## **COMMONLY ASSOCIATED CONDITIONS**

- Infectious etiology
  - Vaginal or vulvar candida
  - *Gardnerella vaginalis*
  - *Trichomonas*
  - Human papillomavirus
  - Herpes simplex virus
- Vulvar vestibulitis
- Lichen sclerosis
- Lichen planus
- Lichen simplex chronicus (squamous cell hyperplasia)
- Malignant or premalignant conditions
- Psoriasis
- Fecal or urinary incontinence
- Dermatophytosis
- Parasites: scabies, phthirus pubis
- Extrammary Paget's
- Dietary: methylxanthines (e.g., coffee, cola), tomatoes, peanuts

- Autoimmune progesterone dermatitis: perimenstrual eruptions
- Irritant or allergic contact dermatitis
- Atopic dermatitis

## DIAGNOSIS

Pruritus vulvae is a diagnosis of exclusion.

### HISTORY

- Persistent itching
- Persistent burning sensation over the vulva or perineum
- Change in vaginal discharge
- Postcoital bleeding
- Dyspareunia

### PHYSICAL EXAM

- Visual inspection of the vulva, vagina, perineum, and anus
  - Superior surfaces of the labia majora—extending from mons to the anal orifice are most involved.
  - Vulvar skin is leathery or lichenified in appearance.
  - Papillomatosis may be a sign of chronic inflammation.
- Light touch identification of affected areas
- Cotton swab-applied pressure to vestibular glands

### DIAGNOSTIC TESTS & INTERPRETATION

- Sodium chloride: *Gardnerella* or *Trichomonas*
- 10% potassium hydroxide: *Candida*
- Viral culture or polymerase chain reaction (PCR): herpes simplex virus
- Directed biopsy: human papillomavirus, lichen, malignancy
- Colposcopy with acetic acid or Lugol solution of vagina and vulva

### Follow-Up Tests & Special Considerations

- A patch test may be performed by a dermatologist to assist in identifying a causative agent if contact dermatitis is suspected.
- Exam-directed tissue biopsies are essential in the postmenopausal population to rule out malignancy.

## *Diagnostic Procedures/Other*

Biopsies should be collected from any ulceration, discoloration, raised areas, macerated areas, and the area of most intense pruritus.

## *Test Interpretation*

- Only in the absence of pathologic findings can the primary diagnosis of pruritus vulvae be made.
- In one study, a specific clinicopathologic diagnosis was obtained in 89% of patients by using the most recent 2006 International Society for the Study of Vulvar Diseases (ISSVD) classifications (2).

## **TREATMENT**

Identify the underlying cause or disease to target treatment

- Stop all potential irritants.
- Eliminate bacterial and fungal infection.
- Cool the affected area: Use cool gel packs (not ice packs, which may cause further injury).
- Sitz baths and bland emollients to soothe fissured or eroded skin

---

P.871

## *MEDICATION*

### *First Line*

- 1st-generation antihistamines (3)[C]
  - Hydroxyzine: Initiate with 10 mg before bedtime (slow increase up to 100 mg).
  - Doxepin: Initiate with 10 mg before bedtime (slow increase up to 100 mg).
  - 2nd-generation antihistamines are of little benefit.
- SSRIs (3)[C]

- Citalopram 20 to 40 mg in the morning may be helpful for daytime symptoms.
- Topical steroids (4)[C]
  - Triamcinolone 0.1% applied daily for 2 to 4 weeks, then twice weekly
  - Hydrocortisone 1-2.5% cream applied 2 to 4 times daily (5)
  - Avoid long-term use due to risk of atrophy.
  - One randomized, controlled trial showed no difference between topical triamcinolone and placebo cream (6).

## *Second Line*

Calcineurin inhibitors such as topical pimecrolimus 1% cream applied BID for 3 weeks (7)[B]

- May lead to an 80% reduction of pruritus

## *ISSUES FOR REFERRAL*

- Persistent symptoms should prompt additional investigation and referral to a gynecologist or gynecologist oncologist.
- Gynecology oncology referral for proven or suspected malignancy
- Dermatology referral for patch testing to evaluate for contact dermatitis

## *ADDITIONAL THERAPIES*

- SC triamcinolone injections (8)[B]
- Alcohol nerve block (9)[B]
- Laser therapy (10)[B]
- GnRH analogue

## **ONGOING CARE**

- Frequent evaluation, repeat cultures, and biopsies are necessary for cases resistant to treatment.
- Refractory cases may require referral to gynecologist or gynecology oncology for further management.

## *DIET*

Dietary alterations include avoidance of the following:

- Coffee and other caffeine-containing beverages
- Tomatoes
- Peanuts

## ***PATIENT EDUCATION***

- American Congress of Obstetricians and Gynecologists: [www.acog.org](http://www.acog.org)
- National Vulvodynia Foundation: [www.nva.org](http://www.nva.org)

## ***PROGNOSIS***

Conservative measures and short-term topical steroids control most patients' symptoms.

## **COMPLICATIONS**

Malignancy

**Codes**

**&NA;**

## **ICD10**

- L29.2 Pruritus vulvae
- N94.819 Vulvodynia, unspecified

## **Clinical Pearls**

**&NA;**

- Most women complain of pruritus vulvae at some point in their lifetime.
- Pruritus vulvae is a diagnosis of exclusion once other causes of itching have been ruled out.
- Exam-directed biopsies from any ulceration, discoloration, raised areas, macerated areas, and the area of most intense pruritus are essential to rule out malignancy.
- Initial treatment is conservative.

# Pseudofolliculitis Barbae

Maurice Duggins, MD

## BASICS

### DESCRIPTION

- Foreign-body inflammatory reaction from an ingrown hair resulting in the appearance of papules and pustules. This is found mainly in the bearded area (*barbae*) but may occur in other hairy locations such as the scalp, axilla, or pubic areas where shaving is done (1).
- A mechanical problem: extrafollicular and transfollicular hair penetration
- System(s) affected: skin/exocrine
- Synonym(s): chronic sycosis barbae; pili incarnate; folliculitis barbae traumatica; razor bumps; shaving bumps; tinea barbae; pseudofolliculitis barbae (PFB)

### EPIDEMIOLOGY

- Predominant age: postpubertal, middle age (14 to 25 years) (2)
- Predominant sex: male > female (can be seen in females of all races who wax/shave)

### Incidence

- Adult male African Americans: unknown
- Adult male whites: unknown

### Prevalence

- Widespread in Fitzpatrick skin types IV-VI (darker complexions) who shave
- 45-83% of African American soldiers who shave (1)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Transfollicular escape of the low-cut hair shaft as it tries to exit the skin is accompanied by inflammation and often an intraepidermal abscess.
- As the hair enters the dermis, more severe inflammation occurs, with downgrowth of the epidermis in an attempt to sheath the hair.

- A foreign-body reaction forms at the tip of the invading hair, followed by abscess formation.
- Shaving too close
- Plucking/tweezing or wax depilation of hair may cause abnormal hair growth in injured follicles.

## *Genetics*

- People with curly hair have an asymmetric accumulation of acidic keratin hHa8 on hair shaft.
- Single-nucleotide polymorphism (disruption Ala12Thr substitution) affects keratin of hair follicle.

## *RISK FACTORS*

- Curly hair
- Shaving too close or shaving with multiple razor strokes
- Plucking/tweezing hairs
- South Mediterranean/American, Middle Eastern, Asian, or African descent (skin types IV-VI)

## *GENERAL PREVENTION*

- Prior to shaving, rinse face with warm water to hydrate and soften hairs.
- Use adjustable hair clippers that leave very low hair length above skin.
- Shave with either a manual adjustable razor at coarsest setting (avoids close shaves), a single-edge blade razor (e.g., Bump Fighter), a foil-guarded razor (e.g., PFB razor), or electric triple head razor.
- Empty razor of hair frequently.
- Shave in the direction of hair growth. Do not overstretch skin when shaving.
- Use a generous amount of the correct shaving cream/gel (e.g., Ef-Kay Shaving Gel, Edge Shaving Gel, Aveeno Therapeutic Shave Gel, Easy Shave Medicated Shaving Cream).
- Daily shaving reduces papules/pruritus.
- Regular use of depilatories

## *COMMONLY ASSOCIATED CONDITIONS*

- Keloidal folliculitis
- Pseudofolliculitis nuchae

# DIAGNOSIS

## HISTORY

Pain on shaving; pruritus of shaved areas, irritated "razor bumps"

## PHYSICAL EXAM

- Tender, exudative, erythematous follicular papules or pustules in beard area (less commonly in scalp, axilla, and pubic areas); range from 2 to 4 mm
- Hyperpigmented razor or shave bumps
- Alopecia
- Lusterless, brittle hair

## DIFFERENTIAL DIAGNOSIS

- Bacterial folliculitis
- Impetigo
- Acne vulgaris
- Tinea barbae
- Sarcoidal papules

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Clinical diagnosis
- Culture of pustules: usually sterile; may show coagulase-negative *Staphylococcus epidermidis* (normal skin flora)
- Additional hormonal testing may be indicated in females with hirsutism and/or polycystic ovary syndrome: dehydroepiandrosterone sulfate, luteinizing hormone (LH)/follicle-stimulating hormone (FSH), and free and total testosterone (3)[C].

### Test Interpretation

Follicular papules and pustules

# TREATMENT

- Mild cases
  - Stop shaving or avoid close shaving for 30 days while keeping beard groomed and clean (1,2)[C].
  - Consider 5% benzoyl peroxide after shaving and application of 1% hydrocortisone cream at bedtime (or LactiCare HC lotion after shaving) (2)[C].
  - Tretinoin 0.025% cream; apply daily(1)[C]
- Moderate cases
  - Chemical depilatories (barium sulfide; Magic Shave powder); first test on forearm for 48 hours (for irritation) (1,2,3)[B]
  - Consider eflornithine HCl cream (Vaniqa) to reduce hair growth and stiffness in combination with other therapies (1,4)[B].
- Severe cases
  - Laser therapy: Longer wavelength laser (e.g., neodymium [Nd]:YAG) is safer for dark skin (5)[B].
  - Avoid shaving altogether; grow beard (1,2,3)[C].

## GENERAL MEASURES

### Acute treatment

- Dislodge embedded hair with sterile needle/tweezers.
- Discontinue shaving until red papules have resolved (minimum 3 to 4 weeks; longer if moderate or severe); can trim to length >0.5 cm during this time.
- Massage beard area with washcloth, coarse sponge, or a soft brush several times daily.
- Hydrocortisone 1-2.5% cream to relieve inflammation
- Selenium sulfide if seborrhea is present and to help reduce pruritus
- Systemic antibiotics if secondary infection is present

### *Pregnancy Considerations*

Do not use tretinoin (Retin-A), tetracycline, or benzoyl peroxide.

# MEDICATION

## First Line

- Topical or systemic antibiotic for secondary infection
  - Application of clindamycin (Cleocin T) solution BID or topical erythromycin
  - Low-dose erythromycin or tetracycline 250 to 500 mg PO BID for more severe inflammation
  - Benzoyl peroxide 5%-clindamycin 1% gel BID: Administer until papule/pustule resolves.
- Mild cases: tretinoin 0.025% cream at bedtime; combination of the above therapies
- Moderate disease/chemical depilatories
  - Disrupt cross-linking of disulfide bonds of hair to produce blunt (less sharp) hair tip.
  - Apply no more frequently than every 3rd day: 2% barium sulfide (Magic Shave) or calcium thioglycollate (Surgex); calcium hydroxide (Nair)
- Contraindications
  - Clindamycin: hypersensitivity history; history of regional enteritis or ulcerative colitis; history of antibiotic-associated colitis
  - Erythromycin, tetracycline, tretinoin: hypersensitivity history
- Precautions
  - Clindamycin: colitis, eye burning and irritation, skin dryness; pregnancy Category B
  - Erythromycin: Use cautiously in patients with impaired hepatic function; GI side effects, especially abdominal cramping; pregnancy Category B (erythromycin base formulation).
  - Chemical depilatories: Use cautiously; frequent use and prolonged application may lead to irritant contact dermatitis and chemical burns.
  - Tetracycline: Avoid in pregnancy.
  - Tretinoin: Severe skin irritation; avoid in pregnancy.
  - Benzoyl peroxide: skin irritation and dryness, allergic contact dermatitis
  - Hydrocortisone cream: local skin irritation, skin atrophy with prolonged use, lightening of skin color
- Significant possible interactions
  - Erythromycin: increases theophylline and carbamazepine levels; decreases clearance of warfarin

- Tetracycline: depresses plasma prothrombin activity

## *Second Line*

Chemical peels with either glycolic acid or salicylic acid

## *ISSUES FOR REFERRAL*

- Worsening or poor response to the above therapies after 4 to 6 weeks should prompt dermatology consultation.
- Occupational demands may also prompt earlier referral to dermatology for more aggressive therapy.

## *SURGERY/OTHER PROCEDURES*

Laser treatment with long-pulsed Nd:YAG is helpful for severe cases.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- As needed
- Educate patient on curative and preventive treatment.

## *DIET*

- No restrictions
- No dietary studies available

## *PATIENT EDUCATION*

- <https://medlineplus.com/>
- <http://www.uptodate.com/home>

## *PROGNOSIS*

- Good, with preventive methods
- Prognosis is poor in the presence of progressive scarring and foreign-body granuloma formation.

## COMPLICATIONS

- Scarring (occasionally keloidal)
- Foreign-body granuloma formation
- Disfiguring postinflammatory hyperpigmentation (use sunscreens; can treat with hydroquinone 4% cream, Retin A, clinical peels)
- Impetiginization of inflamed skin
- Epidermal (erythema, crusting, burns with scarring) and pigmentary changes with laser

## See Also

**&NA;**

Folliculitis; Impetigo

## Codes

**&NA;**

### ICD10

- L73.1 Pseudofolliculitis barbae
- B35.0 Tinea barbae and tinea capitis
- L73.8 Other specified follicular disorders

## Clinical Pearls

**&NA;**

- Electrolysis is not recommended as a treatment. It is expensive, painful, and often unsuccessful.
- Combination of laser therapy with eflornithine is more effective than laser alone.
- Use Bump Fighter razor from American Safety Razor Company (<http://www.asrco.com/>).
- Men may prefer the convenience of the Bump Fighter razor over depilatory products.
- The aversive smell of sulfur could be a problem with some depilatory products.
- Have patient test for skin sensitivity with a small (coin-sized) amount of the depilatory on the bearded area or forearm.

# Pseudogout (Calcium Pyrophosphate Dihydrate)

Caitlyn M. Rerucha, MD

## BASICS

### DESCRIPTION

- Autoinflammatory disease triggered by calcium pyrophosphate dihydrate (CPPD) crystal deposition in the joints
- One of many diseases associated with pathologic deposition of crystal, mineralization, and ossification
  - CPPD crystal deposition = chondrocalcinosis, pseudogout
  - Monosodium urate crystal deposition = gout
  - Hydroxyapatite deposition associated with ankylosing spondylitis, osteoarthritis, and vascular calcification
- Suspect pseudogout in arthritis cases with a pattern of joint involvement not usually affected by degenerative joint disease (e.g., metacarpophalangeal joints, wrists)
- Clinical presentation is broad:
  - Asymptomatic CPPD (incidentally identified on radiograph by chondrocalcinosis with or without additional findings of osteoarthritis)
  - Acute CPPD arthritis (acute onset, self-limiting, synovitis)
  - Chronic CPPD crystal inflammatory arthritis (1)[C]
- Chronic CPPD crystal deposition may cause a progressive degenerative arthritis in numerous joints:
  - Primarily affects the elderly
  - Usually involves large joints
- Symptom onset is usually insidious.
- Definitive diagnosis requires the identification of CPPD crystals in synovial fluid.

- System(s) affected: endocrine/metabolic; musculoskeletal
- Synonyms: pseudogout; CPPD; pyrophosphate arthropathy; chondrocalcinosis when calcification visibly seen within tissues on imaging

## EPIDEMIOLOGY

### Prevalence

- Predominant age: 80% of patients >60 years
- Predominant sex: male > female 1.4:1
- Prevalence varies on method of identification (chondrocalcinosis on radiograph vs. CPPD crystals in synovial fluid)
- Chondrocalcinosis is present in 1:10 adults age 60 to 75 years and 1:3 by >80 years; however, only a small percentage develop arthropathy.
- 20-43% prevalence of CPPD crystals in synovial fluid of osteoarthritic joints at time of joint replacement

## ETIOLOGY AND PATHOPHYSIOLOGY

- Arthropathy results from an acute autoinflammatory reaction to CPPD crystals in the synovial cavity.
- CPPD crystal deposition occurs in three general stages:
  - CPPD crystals first develop in the pericellular matrix of the articular cartilage via overproduction of anionic pyrophosphate (PPi).
  - PPi binds calcium to form CPPD crystals that are released from cartilage surface and elicit an inflammatory response. Neutrophils engulf CPPD crystals, inducing the formation of extracellular traps.
  - Increased deposition of CPPD crystals in and around cartilage causes inflammation and damage. Cartilage degeneration is accelerated through mechanical wear and tear of the joint (2)[C].

### Genetics

Uncommonly seen in familial pattern with autosomal dominant inheritance (<1% of patients); most cases are sporadic. Mutation in ANKH gene increased risk for calcium crystal formation.

## RISK FACTORS

- Advanced age

- Traumatic injury
- CPPD often may occur as a complication in patients hospitalized for other medical and surgical illnesses.

## GENERAL PREVENTION

Colchicine 0.6 mg BID may be used prophylactically to reduce frequency of episodes in recurrent CPPD.

## COMMONLY ASSOCIATED CONDITIONS

- Hyperparathyroidism
- Hemochromatosis
- Gout
- Hypophosphatasia
- Hypothyroidism
- Ochronosis
- Wilson disease
- Amyloidosis
- Hypomagnesemia
- Familial hypocalciuric hypercalcaemia
- X-linked hypophosphatemic rickets
- Acromegaly

## DIAGNOSIS

### HISTORY

- Presentation often mimicks gout ("pseudogout").
- Acute CPPD: pain and swelling of 1 or more joints; knee involved in 50% of cases; ankle, wrist, toe, and shoulder are also common.
- Can present in proximal joints (mimicking polymyalgia rheumatica), often accompanied by tibiofemoral and ankle arthritis and tendinous calcifications
- Multiple symmetric joint involvement (mimicking RA) in <5% of cases
- May develop after intra-articular injection of hyaluronic acid (Hyalgan,

Synvisc)

- Chronic CPPD: progressive degenerative arthritis with superimposed acute inflammatory attacks

## *PHYSICAL EXAM*

- Inflammation (erythema, warmth, tender to touch), joint effusion, decreased range of motion of joint
- 50% associated with fever
- Any synovial joint may be involved.

## *DIFFERENTIAL DIAGNOSIS*

- Illnesses that may cause acute inflammatory arthritis in a single or multiple joint(s):
  - Gout
  - Septic arthritis
  - Trauma
- Other illnesses that may present with an acute inflammatory arthritis:
  - Reiter syndrome
  - Lyme disease
  - Acute RA

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

Synovial fluid analysis shows an inflammatory effusion:

- Cell count 2,000 to 100,000 WBCs/mL
- Differential predominantly neutrophils (80-90%)
- >50,000 WBC count increases likelihood of septic arthritis, 11% prevalence; number needed to treat (NNT) = 9; >100,000 WBCs/mL, 22% prevalence
- Wet prep with polarized microscopy may demonstrate small numbers of crystals. False-negative rate is high.

### **ALERT**

Rhomboid-shaped weakly positively birefringent crystals in the fluid and within

neutrophils is pathognomonic. In contrast, gout crystals are needle-shaped and negatively birefringent.

- Obtain the following metabolic studies in patients <50 years of age and consider in the elderly to exclude underlying disease:
  - Serum calcium, phosphorus, and magnesium
  - Serum alkaline phosphatase
  - Serum parathormone (i-PTH)
  - Serum iron, total iron-binding capacity, and serum ferritin
  - Serum thyroid-stimulating hormone (TSH) level
- Plain radiograph
  - Radiographic findings in pseudogout are neither sensitive nor specific.
  - Punctate and linear calcifications may be visualized in articular hyaline or fibrocartilage (e.g., menisci).
  - Knees, hips, symphysis pubis, and wrists are most commonly affected.
  - Patients with chronic CPPD may demonstrate subchondral cysts and loose bodies (osseous fragmentation with formation of intra-articular radiodense bodies) in joints not typically affected by degenerative joint disease.
- Ultrasound (US)
  - US may be more useful than plain radiography for the diagnosis of pseudogout in peripheral joints, with a positive predictive value of 92% and negative predictive value of 93% (3)[C].
  - US imaging characteristics include joint effusion, synovial thickening, and hyperechoic deposits.
- MRI
  - Chondrocalcinosis may be evident as hypointense lesions on MRI, particularly in association with the menisci of the knee.

## *Diagnostic Procedures/Other*

### **ALERT**

Aspiration of joint fluid with synovial fluid analysis and demonstration of CPPD crystals is required for diagnosis; aspiration may relieve symptoms and speed resolution of the inflammatory process.

## Test Interpretation

CPPD crystal deposition in articular cartilage, synovium, ligaments, and tendons

---

P.875

## TREATMENT

### GENERAL MEASURES

Target symptom relief (reduce inflammation):

- Rest and elevate affected joint(s).
- Apply ice/cool compresses to affected joints.
- Nonweight bearing on affected joint while painful; use crutches or a walker.

### MEDICATION

#### First Line

- A combination of pharmacologic and nonpharmacologic measures is recommended.
- Acute attacks should be treated with cool packs, rest, and joint aspiration with or without steroid injection.
- Chronic inflammatory CPPD arthropathy should be managed prophylactically with oral NSAIDs and/or colchicine (3)[C].
- Oral NSAIDs
  - Ibuprofen 600 to 800 mg PO TID-QID with food; maximum 3.2 g/day
  - Naproxen 500 mg PO BID with food
  - Other NSAIDs at anti-inflammatory doses are effective, although indomethacin has higher complication rates (relative risk [RR] = 2.2) compared with ibuprofen (RR = 1.2).
- Contraindications:
  - History of hypersensitivity to NSAIDs or aspirin
  - Active peptic ulcer disease or history of recurrent upper GI lesions
  - Avoid in renal insufficiency.
  - Serious GI bleeding can occur without warning; patient should be instructed on signs/symptoms. Administer proton pump inhibitor (PPI) or misoprostol 200 *&mgr*;g PO QID

in patients at risk for NSAID-induced gastric ulcers.

- Oral colchicine
  - 0.6 mg QID or 0.6 mg hourly until symptoms relieved or vomiting/diarrhea develops; maximum dose per attack 4 to 6 mg; alternatively 0.5 to 1 mg/day may be used; avoid colchicine with significant renal insufficiency.
- Intra-articular steroid injection
  - Prednisolone-sodium phosphate 4 to 20 mg or triamcinolone diacetate 2 to 40 mg with local anesthetic

## **ALERT**

Significant adverse effects of NSAIDs:

- May elevate BP in patients on antihypertensive therapy
- May blunt antihypertensive effects of ACE inhibitors
- May prolong prothrombin time (PT) in patients taking oral anticoagulants
- Avoid concomitant aspirin use.
- May blunt diuretic effect of furosemide and hydrochlorothiazide
- May increase plasma lithium level in patients taking lithium carbonate

## *Second Line*

- Oral prednisone: 30 to 50 mg/day for 7 to 10 days
- IM triamcinolone acetonide 40 mg; may repeat in 1 to 4 days
- Consider referring patients with large spaceoccupying tophaceous lesions for surgical removal.
- Alternative therapies for chronic CPPD
  - ACTH, Anakinra (anti-IL1), hydroxychloroquine, infliximab, probenecid, magnesium, ethyldiamine tetracetic acid (EDTA) have all been suggested. Large scale studies are needed to evaluate effectiveness (4)[C].

## **ALERT**

Recent randomized trial showed no significant effect of methotrexate in chronic-recurrent CPPD (5)[B].

## *ISSUES FOR REFERRAL*

Consider consultation with orthopedist or rheumatologist if septic joint or patient is not responding.

## ***ADDITIONAL THERAPIES***

Physical therapy

- Isometric exercises to maintain muscle strength during the acute stage (e.g., quadriceps isometric contractions, leg lifts if knee affected)
- Begin joint range-of-motion (ROM) exercises as inflammation and pain subside.
- Resume weight bearing when pain subsides.

## ***SURGERY/OTHER PROCEDURES***

Perform arthrocentesis and joint fluid analysis.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Consider admission for septic arthritis if:

- Synovial fluid WBC count >50,000/mL
- Treat with appropriate antibiotics pending culture results.

## **ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

### ***Patient Monitoring***

Reevaluate response to therapy 48 to 72 hours after beginning treatment; reexamine in 1 week then as needed.

### ***DIET***

No known relationship to diet

## ***PATIENT EDUCATION***

- Rest affected joint.
- Symptoms usually resolve in 7 to 10 days.

## ***PROGNOSIS***

Acute attack usually resolves in 10 days; prognosis for resolution of acute attack is excellent.

- Patients may experience progressive joint damage and functional limitation.

## COMPLICATIONS

- Recurrent acute attacks
- Osteoarthritis

### ***Geriatric Considerations***

Elderly patients treated with NSAIDs require careful monitoring and are at higher risk for GI bleeding and acute renal insufficiency. No loading dose for colchicine due to high rates of renal insufficiency in elderly patients.

## Codes

**&NA;**

### ICD10

- M11.20 Other chondrocalcinosis, unspecified site
- M11.269 Other chondrocalcinosis, unspecified knee
- M11.29 Other chondrocalcinosis, multiple sites

## Clinical Pearls

**&NA;**

- Suspect CPPD if arthritis case doesn't follow a pattern typical of degenerative joint disease (e.g., metacarpophalangeal joints, wrists).
- Perform arthrocentesis to confirm diagnosis.
- If septic arthritis is considered, treat presumptively with antibiotics until culture results are available.
- NSAID therapy is the preferred treatment for acute flare.
- Oral steroids are useful if NSAIDs are contraindicated.
- Intra-articular steroids can be used *if* septic arthritis has been excluded.

# Psoriasis

Edwin A. Farnell IV, MD

Michael O. Needham, MD, CPT, MC, USA

## BASICS

### DESCRIPTION

- A chronic, multisystem inflammatory disorder most commonly characterized by cutaneous erythematous papules and plaques with silvery scale. A complex genetic and immune-mediated disorder with flares related to systemic, psychological, infectious, and environmental factors. Skin disease with multiple different phenotypic variations and degrees of severity.
- Clinical phenotypes
  - Plaque (vulgaris): most common variant (>80% of cases); well-demarcated, scaly, pink-to-red plaques of various sizes; symmetrically distributed on scalp, extensor surfaces of extremities, and trunk
  - Guttate: <2% of psoriasis patients, usually in patients <30 years of age; presents abruptly with 1- to 10-mm droplet-shaped pink papules and fine scale over trunk and extremities; often preceded by group A *β*-hemolytic streptococcal infection 2 to 3 weeks earlier.
  - Inverse: Affects intertriginous areas and flexural surfaces; pink-to-red plaques with minimal scale; absence of satellite pustules distinguishes it from candidiasis although may coexist.
  - Erythrodermic: ±1-2.25% of psoriasis patients; generalized erythema and scaling, affecting >75% of BSA; associated with desquamation, hair loss, nail dystrophy, and systemic symptoms such as fever, chills, malaise, or high-output cardiac failure; may require hospital admission for management of dehydration, electrolyte abnormalities, and high risk of infection
  - Pustular: sterile pustules; several forms including generalized pustular psoriasis, annular pustular psoriasis, and impetigo herpetiformis; generalized type can result in life-threatening bacterial superinfections, sepsis, and dehydration if left untreated
  - Nail disease: pitting, oil spots, and thickening; nails involved in up to 50% of patients with psoriasis with lifetime incidence of 80-90%
  - Psoriatic arthritis: seronegative inflammatory spondyloarthropathy; mono and assymetrical oligoarthritis

# EPIDEMIOLOGY

## Incidence

Predominant sex: male = female. Predominant age: two peaks in incidence between the ages of 20 to 30 years and 50 to 60 years.

## Prevalence

- 2-4.7% similar prevalence in all races
- ÷80% of patients have mild to moderate disease (1).

# ETIOLOGY AND PATHOPHYSIOLOGY

Antigenic triggers activate dendritic cells and T cells; dendritic cells produce type I interferon, and interleukin (IL)-20, which speeds keratinocyte proliferation; myeloid dendritic cells release IL-23 in lymph nodes, recruiting TH1 and TH17 cells to the lesions; T cells produce numerous cytokines, including interferon- $\gamma$ , IL-17, and IL-22 that stimulate keratinocytes to proliferate and produce proinflammatory antimicrobial peptides and cytokines, which recruit neutrophils to the epidermis and activate dermal fibroblasts.

## Genetics

- Genetic predisposition (probably polygenic)
- 40% have psoriasis in a first-degree relative
- Increased incidence of specific human leukocyte antigens (e.g., HLA-Cw6)
- Multiple susceptibility loci contain genes involved in immune system regulation (e.g., psoriasis-susceptibility [*PSORS1*] locus on chromosome 6p21; polymorphisms in the IL-12/IL-13 receptor, the p40 subunit of IL-12 and IL-23, and the p19 subunit of IL-12) (2)

# RISK FACTORS

- Family history
- Local trauma; local irritation (exacerbation)
- HIV; streptococcal infection
- Mental stress (exacerbation)
- Medications (lithium, antimalarials,  $\beta$ -blockers, interferon, withdrawal of steroids)
- Smoking

## GENERAL PREVENTION

Avoid triggers, including trauma, sunburns, smoking, and exposure to certain medications (as mentioned earlier), alcohol, and stress; weight loss if obese.

## COMMONLY ASSOCIATED CONDITIONS

- Psoriatic arthritis
- Obesity, metabolic syndrome, diabetes, CKD
- Cardiovascular disease; atherosclerotic disease
- Nonalcoholic fatty liver disease (NAFLD)
- Autoimmune: alopecia areata, celiac disease, Crohn disease, systemic sclerosis
- Psychiatric/psychologic: depression, suicide, emotional burden/anxiety, alcohol abuse (3)
- Malignancy: lymphoma, nonmelanoma skin cancer with psoralen-UVA (PUVA) therapy

## DIAGNOSIS

### HISTORY

- May include sudden onset of clearly demarcated, erythematous plaques with overlying silvery scales; exacerbation of chronic plaques, especially on extensor surfaces and scalp; typically no or mild pruritus; triggers may include streptococcal/viral infection or trauma.
- Family history of similar condition

## PHYSICAL EXAM

- Well-demarcated salmon pink-to-red erythematous papules and plaques; silvery scale
- Distribution favors scalp, auricular conchal bowls, and postauricular area; extensor surface of extremities, especially knees and elbows; umbilicus, lower back, intergluteal cleft, and nails
- Nail findings: pitting, oil spots, onycholysis, splinter hemorrhages, subungual hyperkeratosis
- Auspitz sign: underlying pinpoints of bleeding following scraping of plaques
- Koebner phenomenon: new psoriatic lesions arising at sites of skin injury/trauma
- Genitals affected up to 40% of patients (4)
- Sebopsoriasis: Psoriasis can overlap with seborrheic dermatitis as greasy scales on the eyebrows, nasolabial folds, and postauricular and presternal areas.

## DIFFERENTIAL DIAGNOSIS

- Plaque: seborrheic dermatitis, nummular eczema, atopic dermatitis, contact dermatitis, lichen planus, lichen simplex chronicus, tinea, pityriasis rubra pilaris, subacute/discoid lupus erythematosus, squamous cell carcinoma in situ
- Guttate: pityriasis rosea, pityriasis lichenoides chronica, lichen planus, secondary syphilis, small plaque parapsoriasis
- Pustular: subcorneal pustulosis, acute generalized exanthematous pustulosis, folliculitis, pemphigus foliaceus
- Erythrodermic: cutaneous T-cell lymphoma, drug-induced erythroderma, ichthyosiform erythroderma

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

Clinical diagnosis based on history and physical exam. May include negative rheumatoid factor, normal erythrocyte sedimentation rate (ESR), and C-reactive protein (elevated in pustular/erythrodermic variants); uric acid level may be elevated in pustular psoriasis; sterile fluid from pustules with neutrophilic infiltrate; fungal studies in hand and foot psoriasis

### *Diagnostic Procedures/Other*

- Psoriasis Area and Severity Index (PASI) evaluates overall severity and body surface area (BSA) involvement.
- Physicians Global Assessment: Target plaque score and the percentage BSA together; 4-mm punch biopsy from affected skin, if necessary
- Dermatology Life Quality Index (DLQI)

### *Test Interpretation*

Biopsy: thickening of the stratum corneum (hyperkeratosis) with retention of nuclei (parakeratosis); elongation, thickening, and clubbing of rete ridges; dilated tortuous capillary loops in the dermal papillae; perivascular lymphocytic infiltrate, Munro microabscesses: neutrophils in stratum corneum

## TREATMENT

## GENERAL MEASURES

Adequate topical hydration (emollients), sun exposure (avoid sunburns), stress relief

## MEDICATION

### First Line

- Mild-to-moderate disease
    - Emollients BID: petrolatum/ointments to maintain skin hydration and minimize pruritus and risk of koebnerization
    - Topical corticosteroids
      - Anti-inflammatory, antiproliferative, immunosuppressive, and vasoconstrictive effects; tachyphylaxis develops over time, may alternate to prevent
      - Local side effects: skin atrophy, hypopigmentation, striae, acne, folliculitis, and purpura. Systemic side effects: Risk is higher, with higher potency formulations used over a large surface for a prolonged period; pregnancy Category C
      - Applications are typically twice daily until lesions flatten/resolve, then taper to PRN use for maintenance.
      - Scalp: strong potency in solution/foam vehicle; shampoos and sprays also available
      - Face, intertriginous areas, infants: low-potency corticosteroids: 1% hydrocortisone
      - Adult initial therapy: medium-potency corticosteroids daily (e.g., 0.1% mometasone or triamcinolone); strong-potency corticosteroids: 0.05% betamethasone or fluocinonide daily; superpotency corticosteroids: clobetasol, halobetasol; limit use to 2 to 4 weeks; avoid occlusive dressings; reserved for recalcitrant plaques
- 
- Vitamin D analogues: calcipotriene 0.005% ointment daily to BID; limits keratinocyte hyperproliferation; may be highly effective for short-term control in combination with a superpotent corticosteroid; should not be used with products that can alter pH, such as topical lactic acid; local side effects: burning, pruritus, edema, peeling, dryness, and erythema; pregnancy Category C
  - Topical retinoids: tazarotene 0.05% or 0.1% (Tazorac) daily; normalizes abnormal keratinocyte differentiation and diminishes hyperproliferation; may be combined with corticosteroids; side effects: local irritation, photosensitivity; pregnancy Category X
  - Topical calcineurin inhibitors: Tacrolimus 0.1% or pimecrolimus 1% may be used as steroid-sparing agents, especially in facial and intertriginous areas.
  - Comparison of topical therapies: vitamin D analogues have slower onset of action than topical corticosteroids, but longer disease-free periods for body plaques. For scalp, potent

P.877

and superpotency steroids more effective (5)[A]

- Combination of superpotent steroids and vitamin D analogs has better efficacy than either as monotherapy or come in combination compounds (6)[A].
- Severe disease: may need combination therapy
  - Light therapy: Locally immunosuppressive and antiproliferative. Natural sunlight; UVB (broad/narrow band [BB, NB]) or PUVA: Treatment protocols are skin type dependent: PUVA most effective, followed by NB-UVB, then BB-UVB (7)[A]; well tolerated, but increased risk of nonmelanoma skin cancers with >350 treatments
  - Systemic therapies
    - Methotrexate: blocks DNA synthesis and inhibits proliferation of lymphoid tissue; start 7.5 to 15 mg/week IV, PO, IM, or SC, then increase 2.5 mg every 2 to 3 weeks, up to 25 mg; contraindicated in pregnancy; supplement with folic acid 1 to 5 mg/day to protect against side effects: hepatotoxicity, pulmonary toxicity, bone marrow suppression; baseline chest x-ray, monitor LFTs, renal function, CBC, testing for latent tuberculosis (TB); consider liver biopsy when cumulative dose reaches 3.5 to 4 g; avoid alcohol and medications that interfere with folic acid metabolism, including Bactrim, sulfamethoxazole, or hepatotoxic agents (e.g., retinoids)
    - Cyclosporine: inhibits T-cell activation; start 2.5 mg/kg/day; if insufficient response after 4 weeks, increase by 0.5 mg/kg/day; additional dosage increases every 2 weeks (max dose: 4 mg/kg/day pregnancy Category C; side effects: renal toxicity and hypertension, limit long-term use: monitor renal function, CBC with  $Mg^{2+}$  and  $K^{+}$ , and BP
    - Acitretin (Soriatane): systemic retinoid; onset ranges from 3 to 6 months; start 25 to 50 mg/day given with the main meal; effective for pustular psoriasis and as a maintenance therapy after stabilization with other agents; sometimes combined with UV-B/PUVA; pregnancy Category X: Pregnancy test before starting; two forms of contraception 1 month before, during, and for at least 3 years after treatment; avoid alcohol (may convert acitretin to etretinate); side effects: alopecia, xerosis, cheilitis, hepatotoxicity, hyperlipidemia, cataracts; monitor LFTs, renal function, lipid profile, CBC, regular eye exams
  - Biologics: general guidelines: Screen for latent TB at baseline and yearly, hepatitis panel at baseline, avoid live vaccines; monitor CBC with differential, signs/symptoms of infections, heart failure, malignancy, drug-induced lupus, inflammatory bowel disease, demyelinating disorder. Some concern for Òbiologic fatigueÓ phenomenon, or loss of PASI 75 over time though each has been shown to be effective at 24 weeks with a NNT <2. All should be considered effective first-line treatments (7,8)[A]; pregnancy Category B.

TNF- $\alpha$  inhibitors: etanercept (Enbrel): begin at 50 mg SC twice a week for 3 months then maintenance of 50 mg/week. Adalimumab (Humira): dosing starts at 80 mg SC for 1 week, then 40 mg SC every other week. Infliximab (Remicade): TNF inhibitor: 5 mg/kg IV at weeks 0, 2, and 6; maintenance doses of 5 mg/kg every 8 weeks thereafter; adjust interval, as needed; anaphylaxis-like infusion reaction occurs in <1% of patients.

- IL-12/IL-23 antagonist: ustekinumab (Stelara): patients <100 kg: 45 mg SC at weeks 0 and 4, then every 12 weeks; >100 kg: 90 mg can be given.

## *Second Line*

Immunosuppressives: azathioprine, hydroxyurea, 6-thioguanine, fumaric acid esters, and topicals: salicylic acid; anthralin

## **ISSUES FOR REFERRAL**

Psoriasis >20% of BSA, severe extremity involvement, particularly hands and feet

## **SURGERY/OTHER PROCEDURES**

Psoriasis and psoriatic medications can affect wound healing postoperatively; methotrexate: Monitor for postoperative infections; hold cyclosporine for 1 week before and after; some surgeons may prefer to hold therapy with biologics for up to 1 month before and after surgery.

## **INPATIENT CONSIDERATIONS**

### *Admission Criteria/Initial Stabilization*

Generalized pustular psoriasis/erythrodermic psoriasis: Rule out sepsis; restoration of barrier function of skin with cleaning and bandaging; intensive topical corticosteroid therapy, phototherapy, systemic therapy, particularly medications with a quick onset such as oral cyclosporine; management of electrolytes

## **ONGOING CARE**

### **FOLLOW-UP RECOMMENDATIONS**

Measure BSA involvement to determine if therapy is working; change therapy or add agent if no improvement is seen.

### **DIET**

Well-balanced diet and exercise to limit cardiovascular risk factors and decrease risk of associated conditions, including obesity, metabolic syndrome, diabetes, and atherosclerosis.

# PATIENT EDUCATION

National Psoriasis Foundation: [www.psoriasis.org](http://www.psoriasis.org); 800-723-9166

## PROGNOSIS

Guttate form may be self-limited and remit after 4 months; chronic plaque type is lifelong, with intermittent spontaneous remissions and exacerbations; erythrodermic and generalized pustular forms may be severe and persistent.

## COMPLICATIONS

Psoriatic arthritis, generalized pustular psoriasis, erythrodermic psoriasis

- L40.9 Psoriasis, unspecified
- L40.50 Arthropathic psoriasis, unspecified
- L42 Pityriasis rosea

## Clinical Pearls

&NA;

Chronic lifelong inflammatory skin condition with remissions and exacerbations; set realistic expectations with patient. Disease burden not limited to skin. If one medication does not work, use/combine with another agent.

# Psychosis

Robert A. Baldor, MD, FAAFP

## BASICS

### *DESCRIPTION*

Syndrome seen with schizophrenia, schizoaffective disorder, mood disorder, substance use, medical problems, delirium, and dementia; symptoms include the following:

- Positive symptoms: hallucinations and delusions (fixed false and often paranoid beliefs created as the patient loses the ability to correct errors in thinking)
- Negative symptoms: apathy, avolition, withdrawal
- Disorganized speech/behavior
- Cognition: decreased working memory, difficulty with attention, poor and slow information interpretation

### *EPIDEMIOLOGY*

#### *Prevalence*

- Schizophrenia: peak onset 18 to 25 years in men; women peak onset 25 to 35 years
  - 1% of the U.S. population; thought to be similar worldwide
- Delusional disorder: 0.03% of population
- Bipolar type I: 1% of population
- Prevalence in major depression not known

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Neurodevelopmental predisposition plus 1st/3rd trimester in utero insult (e.g., 1st-trimester infection or 3rd-trimester birth hypoxia) leads to exaggerated neuronal apoptosis in late adolescence with subsequent thalamic sensory overload. Increased dopaminergic mesolimbic transmission may contribute to delusions and hallucinations in schizophrenia. Dopamine deficiency in mesocortical pathways may contribute to frontal lobe hypoactivity often associated with apathy and withdrawal in schizophrenia. Glutamate, neurosteroids, and

neurodevelopmental abnormalities are active areas of research.

- Postulated stress-diathesis model: Individuals biologically at risk develop psychosis when under stress.

## *Genetics*

Schizophrenia: 50% concordance for monozygotic twins, little or no shared environmental effect; multiple candidate genes involving disruption of neurodevelopment

## **RISK FACTORS**

Substance abuse (particularly marijuana), family history of psychosis, lower socioeconomic status

## **GENERAL PREVENTION**

Community interventions for early detection and treatment of prodromal symptoms show promise.

## **COMMONLY ASSOCIATED CONDITIONS**

- Serious mental illness is associated with metabolic syndrome, autonomic dysfunction, and sudden cardiac death.
- Cancer mortality: particularly breast and lung cancer
- Substance abuse disorders, including nicotine dependence

## **DIAGNOSIS**

First, rule out delirium: Psychosis should not have fluctuating consciousness/reduced clarity of awareness.

### **HISTORY**

- Delusions (fixed false beliefs): persecutory (being monitored), bizarre (involving impossible states), somatic (fixed belief in nonexistent serious illness), referential (getting messages from TV, radio, or thoughts inserted/deleted by others), grandiose (belief that one has special powers)
- Hallucinations: auditory, visual, tactile
- Bipolar illness, depression, and dementia are all associated with psychosis, so screen for symptoms of depression, mania, and memory loss.
- Screen for toxidromes of drugs of abuse.
- Screen for history of epileptiform activity.

Suicidality: higher risk with comorbid depression/mania, previous suicide attempts, drug abuse, agitation/akathisia, poor compliance

## PHYSICAL EXAM

- Mental status exam: disorganized idea sequencing and/or error correction, not incorrect thought content, is the *condicio sine qua non* of schizophrenia. Patients often have negative symptoms (e.g., social withdrawal, lack of initiative, poverty of thought) and disorganized behavior.
- Attention to neurologic focalities, antipsychotic-induced parkinsonism, tardive dyskinesia, and akathisia
- May rarely present with catatonia: extreme excitement/lack of movement; posturing, mutism, grimacing, waxy flexibility

## DIFFERENTIAL DIAGNOSIS

- Schizophrenia: positive symptoms (psychosis) and negative symptoms (flat affect), prodrome of social withdrawal, cognitive impairment; schizophreniform disorder: psychotic/prodromal symptoms in <6 months; schizoaffective disorder: manic/depressive mood disorder with hallucinations/delusions that persist even when euthymic; schizotypal personality disorder: no true psychosis but distance in relationships and odd beliefs; delusional disorder: nonbizarre delusion (e.g., erotomanic, grandiose, jealous, persecutory, somatic), no negative/mood symptoms
- Mood disorder with psychotic features: can occur in mania/depression. Delusions often mood-congruent; psychosis remits when mood improves.
- Substance-induced psychosis: alcohol and benzodiazepine withdrawal, intoxication with cocaine, bath salts, PCP, cannabis, amphetamines, hallucinogens, and alcohol. May persist beyond acute intoxication
- Borderline personality disorder: During extreme stress, patients often experience auditory/visual hallucinations (psychosis NOS).
- Posttraumatic stress disorder: psychosis associated with traumatic recollections. Often visual hallucinations (vs. more auditory in schizophrenia)
- Psychosis due to general medical condition: delirium, stroke, infection, collagen vascular disease, head injury, tumor, interictal, porphyria, syphilis, and so forth
- Medication-induced psychosis: common causes: steroids, L-dopa, anticholinergic medication, antidepressants in bipolar patients, interferon, digoxin, stimulants

## DIAGNOSTIC TESTS & INTERPRETATION

Test for causes of delirium mimicking psychosis, if uncertain.

- Broad screen for medical causes: CBC, metabolic panel, LFTs, thyroid-stimulating hormone (TSH), rapid plasma reagin (RPR), HIV, vitamin B<sub>12</sub>, U/A, and screens for subclinical infection in elderly
- Screen for drugs of abuse.
- No imaging necessary for diagnosis. Consider MRI/CT to evaluate for medical cause of symptoms, especially if new onset or in elderly. In research studies, schizophrenia is associated with enlarged lateral ventricles and less frontal activity.

## Follow-Up Tests & Special Considerations

Because of elevated risk related to schizophrenia and psychotropic medications, screen for metabolic syndrome.

- Consider Wilson disease, porphyria, metachromatic leukodystrophy, inflammatory conditions.
- Consider ECG: Antipsychotics can prolong corrected QT (QTc) interval, particularly ziprasidone, thioridazine, droperidol, IV haloperidol
- Consider lumbar puncture if unable to distinguish from delirium and/or unexplained rapid-onset psychosis.
- Consider electroencephalogram (EEG) for partial complex seizures and psychosis associated with preictal and postictal events.

## TREATMENT

Before antipsychotic treatment, lipid profile, fasting blood sugar, LFTs, metabolic panel, weight (1)[B]

## MEDICATION

- Antipsychotics are the mainstay of treatment (1)[B].
- Classified as typical versus atypical. Dopamine-2 (D<sub>2</sub>) antagonists with varied affinity for the receptor. Atypicals also block serotonin 5-HT<sub>2A</sub> receptors. Help positive symptoms more than negative. Nonspecific effect on agitation begins early; antipsychotic effect takes 1 to 6 weeks.
- For mania with psychotic features, a mood stabilizer may be used with an antipsychotic.
- For major depression with psychotic features, antidepressant and antipsychotic medications yield better response rate than either medication alone.

- In delirium, must treat underlying cause
- Risks of antipsychotic medications include the following:
  - Acute dystonia: Use 1 to 3 mg IM/IV benztropine initially, then 0.5 to 2 mg BID-TID or diphenhydramine 50 to 100 mg IM/IV BID-TID max 400 mg/day.
  - Parkinsonism: Lower antipsychotic dose; switch to atypical (particularly, quetiapine, olanzapine, or clozapine) or add benztropine 0.5 to 2 mg PO BID-TID, diphenhydramine 25 to 50 mg BID-TID.
  - Akathisia: intense restlessness, especially legs. Lower antipsychotic dose; treat with  $\beta$ -blocker, anticholinergic, or benzodiazepine; may switch to antipsychotic with lower risk for akathisia such as quetiapine, olanzapine, iloperidone, or clozapine
  - Tardive dyskinesia: 20% of those treated long-term with typicals. Switch to clozapine or quetiapine. If cannot, minimize dose.

P.879

- Neuroleptic malignant syndrome: potentially fatal; rigidity, tremor, fever, autonomic instability, mental status changes; discontinue neuroleptic; ICU; volume resuscitation; cooling blankets; no anticholinergics/antihistaminics; consider dantrolene, amantadine, bromocriptine electroconvulsive therapy (ECT).
- Metabolic syndrome, sudden cardiac death (risk higher IM/IV droperidol, IV haloperidol), stroke (elderly), QTc prolonged, pulmonary embolus

## First Line

- Benefits of some of the atypical antipsychotics include low risk of extrapyramidal symptoms (quetiapine, olanzapine, iloperidone, or clozapine) and tardive dyskinesia (clozapine, quetiapine); possibly more effective for negative symptoms
- Greater risk of weight gain, new-onset diabetes, and hyperlipidemia with olanzapine and clozapine compared with typicals and some of the other atypicals (ziprasidone, aripiprazole)
- Acute psychotic agitation: olanzapine 5 to 10 mg IM with up to three 10-mg injections over a 24-hour period, care with subsequent benzodiazepines; ziprasidone 10 mg IM q2h or 20 mg q4h; max 40 mg over a 24-hour period; haloperidol/lorazepam 5 mg/2 mg IM often with 1 mg IM benztropine, max 20 mg haloperidol, and 8 mg lorazepam over a 24-hour period
- Psychosis in schizophrenia
  - Olanzapine: Start 5 to 10 mg at bedtime, target dose 5 to 20 mg/day within 2 days and up to 40 mg/day in treatment-refractory schizophrenia. More likely weight gain, hyperlipidemia, and hyperglycemia than other oral atypicals except clozapine; may have lower rates of

discontinuation and rehospitalization than several other atypicals but likely not more efficacy than clozapine. Sedation initially

- Quetiapine: Start 25 mg BID 25 to 50 mg BID-TID on days 2 and 3, up to 300 to 400 mg in divided doses by day 4. Within 2 weeks, up to 400 to 800 mg/day divided BID-TID; less parkinsonism, useful in Parkinson disease psychosis; more weight gain than aripiprazole, lurasidone, ziprasidone; sedation, restless legs syndrome; more gradual titration tolerated better. Quetiapine XR can start 300 mg/day. Dose increases can be within 1 day and up to 300 mg/day, but slower start and titration may be better; target dose 300 to 800 mg at bedtime
- Risperidone: Start 1 to 2 mg/day; target dose of 2 to 6 mg/day to be reached over 1 to 2 weeks; doses >6 mg rarely more effective and higher risk of parkinsonism. Higher risk of prolactinemia/parkinsonism than clozapine, quetiapine, olanzapine
- Paliperidone: Start 3 to 6 mg/day target dose 6 to 12 mg/day; titrate over 1 to 2 weeks. Higher risk of prolactinemia/parkinsonism than clozapine, quetiapine, olanzapine
- Ziprasidone: Start 20 to 40 mg PO BID, with target dose of 100 to 200 mg/day in divided doses over 2 weeks; prolongs QTc; less likely to cause weight gain than other atypicals; higher risk of akathisia/parkinsonism than clozapine, quetiapine, olanzapine. Requires meal. Often sedation
- Aripiprazole: Start 10 to 15 mg/day, may increase up to 30 mg/day over a week or 2; less weight gain but higher rates of akathisia/parkinsonism than clozapine, quetiapine, olanzapine
- Asenapine: Start 5 mg at bedtime or BID sublingually, increase to 10 mg BID if needed over a week or 2; less weight gain than some, higher rates of akathisia/parkinsonism than clozapine, quetiapine, olanzapine; sedation, orthostatic hypotension, numb tongue, nausea, bad taste
- Lurasidone: Start 20 to 40 mg once daily with food (at least 350 calories), increase to 80/120 mg at bedtime if needed over 2 to 4 weeks. Less weight gain than some but higher rates of akathisia/parkinsonism than clozapine, quetiapine, olanzapine; not antihistaminic but  $\alpha_1$ -blocking sedation and serotonergic nausea
- Iloperidone: Start 1 mg BID, may increase by 2 mg BID each day, but slower can be better due to significant orthostasis. Increase to max 12 mg BID. Little akathisia/parkinsonism, less weight gain than olanzapine or clozapine but slower efficacy due to long titration, orthostasis, sedation

## *Geriatric Considerations*

Increased risk of cerebrovascular accident when antipsychotics are used in the elderly with

## *Second Line*

- Clozapine: more effective for reducing symptoms, preventing relapse, decreasing tardive dyskinesia, and decreasing suicidality than other antipsychotics but second line given risk of fatal agranulocytosis. National registry for all patients on clozapine, weekly CBC and absolute neutrophil count (ANC) for 6 months then every 2 weeks for 6 months, then every 4 weeks. More weight gain, hyperlipidemia, hyperglycemia, seizures, myocarditis, pulmonary embolus, and sedation but low rate of parkinsonism, tardive dyskinesia. Useful in treatment-refractory psychosis and in Parkinson disease psychosis
- Despite association with more weight gain than other antipsychotics, clozapine and olanzapine do not appear to increase risk of cardiac and all-cause mortality (2,3)[B].
- Long-acting preparations: available for 2 typicals (haloperidol and fluphenazine) and 4 atypicals (risperidone, paliperidone, olanzapine, aripiprazole; olanzapine requires registration due to rare delirium syndrome). Test tolerability with oral medication first. Long-acting antipsychotics promote compliance.
- Long-acting haloperidol, paliperidone, olanzapine, aripiprazole administered every 4 weeks; long-acting risperidone and fluphenazine administered every 2 weeks.

## *ISSUES FOR REFERRAL*

Encourage contact with advocacy groups for families and patients (National Alliance for the Mentally III).

## *ADDITIONAL THERAPIES*

Cognitive-behavioral therapy (CBT) is an effective adjuvant to antipsychotics (1)[B].

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

At risk for harm to self or others; extreme functional impairment; unable to care for self; new-onset psychosis

### *Discharge Criteria*

No longer a danger to self or others and adequate outpatient treatment in place

**ONGOING CARE**

## FOLLOW-UP RECOMMENDATIONS

Close follow-up for inpatient discharge (high risk for suicide), use CBT, exercise, teach smoking cessation

## PATIENT EDUCATION

National Alliance on Mental Illness: [www.nami.org/](http://www.nami.org/)

## PROGNOSIS

Schizophrenia: Fluctuating course, 70% first-episode psychosis patients improve in 3-4 months; 7% will die of suicide; 20-40% will attempt suicide.

**See Also**

**&NA;**

Delirium; Schizophrenia

## Codes

**&NA;**

### ICD10

- F29 Unsp psychosis not due to a substance or known physiol cond
- F20.9 Schizophrenia, unspecified
- F39 Unspecified mood [affective] disorder

## Clinical Pearls

**&NA;**

- Antipsychotics are the mainstay of treatment; evidence corroborates decreased all-cause mortality in patients who are adherent to these medications.
- Clozapine and long-acting preparations are likely underused in schizophrenia in the United States and may increase adherence, whereas newer atypicals (quetiapine, lurasidone, aripiprazole, olanzapine-fluoxetine combination) may help with depressive symptoms in psychosis.

# Pulmonary Arterial Hypertension

Urooj Najm, MBBS

Najm Hasan Siddiqui, MD

## BASICS

### DESCRIPTION

- Pulmonary arterial hypertension (PAH) is a category of pulmonary hypertension (PH) characterized by abnormalities in the small pulmonary arteries (precapillary PH) that produce increased pulmonary arterial pressure (PAP) and vascular resistance, eventually resulting in right-sided heart failure. PAH is a progressive disorder associated with increased mortality.
  - Previously, PH was classified as primary PH (without cause: now idiopathic pulmonary arterial hypertension [IPAH]) or secondary PH (with cause or associated condition); now it is clear that some types of secondary PH closely match primary PH (IPAH) in their histology, natural history, and response to treatment. Therefore, WHO classifies PH into five groups based on mechanism, with PAH as group 1 in this classification.
- PAH is diagnosed by right-heart catheterization and defined by:
  - Mean PAP  $\geq$ 25 mm Hg at rest
  - Pulmonary capillary wedge pressure  $\leq$ 15 mm Hg (to exclude PH owing to left heart disease; i.e., group 2 PH)
  - Mild or absent chronic lung disease or other causes of hypoxemia (excludes PH owing to lung disease or hypoxemia; i.e., group 3 PH)
  - Absent venous thromboembolic disease (excludes chronic thromboembolic PH; i.e., group 4 PH)
  - Absent systemic disorder (like sarcoidosis), hematologic disorders (like myeloproliferative disease), and metabolic disorders (like glycogen storage disease). Purpose is to exclude group 5 PH.
- PAH is divided into following main categories:
  - Idiopathic: sporadic, with no family history or risk factors
  - Heritable: IPAH with mutations or familial cases with or without mutations

- Drug- or toxin-induced: mostly associated with anorectics (e.g., fenfluramine), rapeseed oil, L-tryptophan, and illicit drugs such as methamphetamine and cocaine
  - Associated: connective tissue diseases (e.g., systemic lupus erythematosus, rheumatoid arthritis, scleroderma), HIV infection, portal hypertension, congenital heart disease, schistosomiasis, chronic hemolytic anemia (e.g., sickle cell disease)
  - Pulmonary veno-occlusive disease (PVOD) and/or pulmonary capillary hemangiomatosis (PCH) and persistent pulmonary hypertension of the newborn (PPHN) are classified as separate categories due to more differences than similarities with PAH.
    - PVOD and/or PCH: rare cause of PH characterized by extensive diffuse occlusion of the pulmonary veins (unlike PAH which involves the small muscular pulmonary arterioles)
  - PPHN
- System(s) affected: pulmonary, cardiovascular

## *EPIDEMIOLOGY*

- Age: can occur at any age; mean age, 37 years
- Sex (IPAH): female > male (÷4:1)

## *Incidence*

- Overall PAH: 5 to 52 cases/million
- IPAH: low, ÷2 to 6 per million
- Drug-induced PAH: 1/25,000 with >3 months of anorectic use
- HIV-associated: 0.5/100
- Portal hypertension-associated: 1 to 6/100
- Scleroderma-associated: 6-60%

## *Prevalence*

- PAH: ÷15 to 50 cases per million
- IPAH: ÷6 cases per million

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Pulmonary: Inflammation, vasoconstriction, endothelial dysfunction, and remodeling of pulmonary arteries produced by increased cell proliferation and reduced rates of apoptosis lead to obstruction.

- Cardiovascular: right ventricular hypertrophy (RVH), eventually leading to right-sided heart failure
- IPAH: by definition, unknown. True IPAH is mostly sporadic or sometimes familial in nature.
- Pulmonary arteriolar hyperactivity and vasoconstriction, occult thromboembolism, or autoimmune (high frequency of antinuclear antibodies)

## Genetics

- 75% of heritable pulmonary arterial hypertension (HPAH) cases and 25% of IPAH cases have mutations in *BMPR2* (autosomal dominant).
- Mutations in *ALK1* and endoglin (autosomal dominant) also are associated with PAH.

## RISK FACTORS

- Female sex
- Previous anorectic drug use
- Recent acute pulmonary embolism
- Commonly associated conditions
- First-degree relatives of patient with familial PAH

## COMMONLY ASSOCIATED CONDITIONS

See associated PAH, earlier discussed.

## DIAGNOSIS

Symptoms of PAH are nonspecific, which can lead to missed or delayed diagnosis of this serious disease.

### HISTORY

Dyspnea, weakness, syncope, dizziness, chest pain, palpitations, lower extremity edema

## PHYSICAL EXAM

- Pulmonary component of  $S_2$  (at apex in >90% of patients)
- Right ventricular (RV) lift
- Early systolic click of pulmonary valve

- Pansystolic murmur of tricuspid regurgitation
- Diastolic murmur of pulmonic insufficiency (Graham-Steell murmur)
- RV S<sup>3</sup> or S<sup>4</sup>
- Edema as jugular vein distention, ascites, hepatomegaly, or peripheral edema

## *DIFFERENTIAL DIAGNOSIS*

Other causes of dyspnea:

- Pulmonary parenchymal disease such as chronic obstructive pulmonary disease
- Pulmonary vascular disease such as pulmonary thromboembolism
- Cardiac disease such as cardiomyopathy
- Other disorders of respiratory function such as sleep apnea

## *DIAGNOSTIC TESTS & INTERPRETATION*

- ECG: RVH and right axis deviation
- Pulmonary function testing and/or arterial blood gas: arterial hypoxemia, reduced diffusion capacity, hypocapnia
- Ventilation-perfusion ratio (V/Q) scan: must rule out proximal pulmonary artery emboli and chronic thromboembolic PH (CTEPH)
- Exercise test: reduced maximal O<sub>2</sub> consumption, high-minute ventilation, low anaerobic threshold, increased PO<sub>2</sub> alveolar-arterial gradient; correlation to severity of disease with 6-minute walk test
- Antinuclear antibody positive (up to 40% of patients)
- LFTs to evaluate for portopulmonary HTN, a complication of chronic liver disease
- HIV test, thyroid function tests, sickle cell disease screening
- Elevated brain natriuretic peptide (BNP) and N-terminal-proBNP may be useful for early detection of PAH in young, otherwise healthy patients with mild symptoms. It can also be used to assess disease severity and prognosis.
- Chest radiograph
  - Prominent central pulmonary arteries with peripheral hypovascularity of pulmonary arterial branches
  - RV enlargement is a late finding.

- Echo Doppler
  - Should be performed with suspicion of PAH; recent studies show some inaccuracy compared with right-sided heart catheterization
  - Most commonly used screening tool
    - Estimates mean PAP and assesses cardiac structure and function, excludes congenital anomalies
    - Echo suggests, but does not diagnose, PAH. Invasive hemodynamic evaluation confirms PAH diagnosis.
- Right atrial and ventricular enlargement; tricuspid regurgitation
- Important to rule out underlying cardiac disease such as atrial septal defect with secondary PH or mitral stenosis
- Cardiac magnetic resonance is not commonly used.

### *Diagnostic Procedures/Other*

- Pulmonary angiography
  - Should be done if V/Q scan suggests CTEPH
  - Use caution; can lead to hemodynamic collapse; use low osmolar agents, subselective angiograms.
- Right-sided cardiac catheterization (gold standard for diagnosis of PAH)
  - Essential first step to confirm diagnosis and determine severity and prognosis by measuring pulmonary arterial pressures and hemodynamics
  - Rule out underlying cardiac disease (e.g., left-sided heart disease) and response to vasodilator therapy.
- Lung biopsy: not recommended unless primary pulmonary parenchymal disease exists
- 6-Minute walk test: classifies severity of PAH and estimates prognosis

### *Test Interpretation*

- Distal arterioles show medial hypertrophy, proliferative/fibrotic intima, complex lesions, and thrombosis.
- Pulmonary veins usually are not affected.

## TREATMENT

- Treat underlying diseases/conditions that may cause PAH to relieve symptoms and improve quality of life and survival.
- PAH-specific treatment has been studied mostly in IPAH.

P.881

## GENERAL MEASURES

Oxygen supplementation to  $O_2 >90\%$  is indicated for rest, exercise, or nocturnal hypoxemia.

## MEDICATION

- Acute vasodilator test (performed during cardiac catheterization) for all IPAH patients who are potential candidates for long-term oral calcium channel blocker (CCB) therapy
  - Screens for pulmonary vasoreactivity/responsiveness using inhaled nitrous oxide; IV epoprostenol or IV adenosine: Positive response may be a prognostic indicator.
  - Contraindicated in right-sided heart failure or hemodynamic instability
- Chronic vasodilator therapy
  - If IPAH with positive response to acute vasodilator test (a fall in mean PAP of  $\geq 10$  mm Hg and to a value  $<40$  mm Hg, with unchanged/increased cardiac output), use CCBs (1)[C]
    - $\approx 13\%$  will initially respond. Long-term clinical response to CCB therapy is small ( $\approx 7\%$ ) (1)[C].
    - CCBs include nifedipine (long-acting), diltiazem, amlodipine.
    - Avoid verapamil due to its significant negative inotropic effect.
    - CCBs are contraindicated in patients with a cardiac index of  $<2$  L/min/m<sup>2</sup> or a right atrial pressure  $>15$  mm Hg.
  - PAH with negative response to acute vasodilator test or worsening on therapy; specific vasodilator choice based on risk stratification (1)[C].
    - Higher risk (NYHA class III-IV): prostacyclins: improve exercise capacity, cardiopulmonary hemodynamics: epoprostenol (IV) (only drug with demonstrated survival benefit and treatment of choice for most ill; i.e., NYHA functional class IV patients) (1)[B]; treprostinil (IV, SC, or inhaled); iloprost (inhaled); inhaled products associated with bronchospasm

FDA recently approved treprostinil extended-release tablets for PAH to improve exercise capacity.

- Lower risk (NYHA class I-III)
  - Endothelin receptor antagonists: Improve exercise capacity; reducing mortality has been noted (2)[A]: bosentan (PO); ambrisentan (PO). Pregnancy Category X; monitor LFTs monthly.
  - Phosphodiesterase-5 inhibitors: suggested improvement in exercise capacity, cardiopulmonary hemodynamics, and symptoms (1)[C]: sildenafil (PO); tadalafil (PO)
  - Guanylate cyclase stimulant: stimulators of the nitric oxide receptor, improves exercise capacity (3)[B]: riociguat (PO)
  - It is unclear whether any of the above separate classes of drugs significantly reduces mortality; however, pooling all the vasodilators in a recent systematic review shows 39% reduction in mortality (4)[A]; another recent meta-analysis shows that only prostanoid class has survival benefit, particularly IV prostacyclins (1)[B].
  - If one agent fails, vasodilator combination therapy (CT) using two vasodilators (e.g., epoprostenol plus sildenafil) is currently being studied. A recent meta-analysis found CT did not improve outcomes compared with monotherapy (MT). Only 6-minute walk distance was improved when using CT versus MT (5)[A].
- Anticoagulation
  - Improved survival originally suggested in patients with IPAH only. Newer studies show some evidence for favorable effects of anticoagulation on survival in IPAH, HPAH, or PAH associated with anorexigens (1)[B].
  - Warfarin with international normalized ratio of 1.5 to 2.5
    - Contraindications: Avoid in patients with syncope or significant hemoptysis; consider drug interactions.
- Diuretics indicated in patients with RV volume overload (e.g., peripheral edema or ascites) (1)[B]
- Digoxin has little long-term data in PAH: used in RV failure and/or atrial dysrhythmias, increases cardiac output and preserves RV contractility

## **ISSUES FOR REFERRAL**

Refer to a pulmonologist and/or a cardiologist for further evaluation/treatment if PAH is suspected.

## ***SURGERY/OTHER PROCEDURES***

- Patients with documented large-vessel thromboembolic disease should be considered for pulmonary thrombectomy.
- Balloon atrial septostomy for severe PAH with right-sided heart failure despite optimized medical therapy to relieve symptoms prior to lung transplant or as a treatment on its own
- Heart-lung or lung transplantation

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Medical therapy is primarily palliative.
- Hospitalization with invasive monitoring is needed to screen vasodilator responsiveness and initiate vasodilator therapy.
- National registry has been established by the National Heart, Lung, and Blood Institute.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Pneumococcal and influenza vaccines
- Exercise: walking or low-level aerobic activity, as tolerated, once stable; respiratory training

### ***Patient Monitoring***

Frequently evaluate disease progression and therapeutic efficacy. Objective tests to measure treatment response include 6-minute walk test and cardiopulmonary exercise test.

### ***DIET***

Fluid and salt restrictions, especially with RV failure

### ***PATIENT EDUCATION***

Discuss disease, prognosis, lifestyle changes, and all therapeutic options (including transplant).

### ***PROGNOSIS***

- Median survival is 2 to 3 years from diagnosis; 5-year survival rate is 34% for National Institutes of Health registry; newer studies show 5-year survival near 70% with new

treatment.

- Mode of death: right-sided heart failure (most common), pneumonia, sudden death, cardiac death
- Poor prognostic factors
  - Rapid symptom progression
  - Clinical evidence of RV failure
  - WHO functional PAH class 4 (or NYHA functional class III or IV)
  - 6-Minute walk distance <300 m
  - Peak  $VO_2$  during cardiopulmonary exercise testing <10.4 mL/kg/min
  - Echocardiography with pericardial effusion, significant RV enlargement/dysfunction, right atrial enlargement
  - Mean right atrial pressure >20 mm Hg
  - Cardiac index <2 L/min/m<sup>2</sup>
  - Elevated mean PAP
  - Significantly elevated BNP and NT-proBNP; other markers also show promise in predicting survival: RDW, GDF-15, interleukin-6, creatinine
  - Scleroderma spectrum of diseases

## COMPLICATIONS

- Thromboembolism, heart failure, pleural effusion, and sudden death
- Pregnancy should be avoided due to high maternal mortality (30-50%) and fetal wastage.

&NA;

Cor Pulmonale; Pulmonary Embolism

## Codes

&NA;

## ICD10

- I27.0 Primary pulmonary hypertension
- I27.2 Other secondary pulmonary hypertension

## Clinical Pearls

&NA;

- PAH involves abnormalities in the small pulmonary arteries (precapillary PH) that produce increased PAP and vascular resistance, eventually resulting in right-sided heart failure.
- In patients with PAH, a V/Q scan should be performed to rule out CTEPH; a normal scan effectively excludes a diagnosis of CTEPH.
- CCBs are the first-line agents to manage IPAH.

# Pulmonary Edema

Timothy R. Takagi, MD

## BASICS

### DESCRIPTION

- Pulmonary capillaries leak fluid into the lung interstitium and alveoli, leading to hypoxia and respiratory distress.
- Fluid accumulation results from cardiogenic causes (e.g., heart failure), leading to imbalanced hydrostatic and oncotic pressures within pulmonary capillaries or from noncardiogenic causes (e.g., acute lung injury) that increase alveolar membrane permeability.

### EPIDEMIOLOGY

#### *Incidence*

- Annual heart failure incidence: 650,000 cases
- Heart failure incidence increases with age.
  - Age 35 to 64 years: 2 cases per 1,000
  - Age 65 to 69 years: 20 cases per 1,000
  - Age >85 years: >80 cases per 1,000
- Disparities in heart failure incidence by race and sex
  - Blacks (16.3/1,000) versus whites (11.9/1,000)
  - Men (15.8/1,000) versus women (11.7/1,000)
- Acute respiratory distress syndrome (ARDS): 190,000 cases annually in United States

#### *Prevalence*

Heart failure syndromes: 5.8 million U.S. adults

### ETIOLOGY AND PATHOPHYSIOLOGY

- Cardiogenic causes will increase hydrostatic pressure in the pulmonary capillaries, leading to

increased transvascular filtration of a protein-poor fluid into lung interstitium.

- Systolic dysfunction is due to decreased contractility of the left ventricle (LV), leading to decreased cardiac output, which in turn stimulates the renin-angiotensin system and increases fluid retention. Diastolic dysfunction is often due to decreased LV compliance secondary to hypertrophy.
- Cardiogenic (left-sided heart failure)
  - Impaired contractility
    - Ischemic heart disease
    - Dilated cardiomyopathy
    - Myocarditis
    - Volume overload
    - Alcoholic cardiomyopathy
  - Increased LV afterload
    - Systemic hypertension (HTN)
    - Aortic stenosis
    - Cocaine abuse
  - Poor diastolic filling
    - LV hypertrophy
    - Hypertrophic cardiomyopathy
    - Mitral stenosis
    - Atrial fibrillation
  - Valvular dysfunction
    - Mitral regurgitation
    - Acute papillary muscle rupture
  - High cardiac output states
    - Thyrotoxicosis
    - Systemic arteriovenous fistulas
    - Anemia

- Noncompliance with medications or diet
- Medications with negative inotropic effects
- Noncardiogenic causes will increase permeability of the lung vasculature, leading to accumulation of protein-rich fluid in the lung interstitium and air spaces. Many causes of this vascular permeability are associated with ARDS.
- Noncardiogenic
  - ARDS
  - Acute lung injury
  - Transfusion-related acute lung injury
  - Preeclampsia
  - Rapid ascent to high altitude (>2,500 m)
  - Drug toxicity (salicylates, opiates)
  - Embolism (thrombus, fat, air, amniotic fluid)
  - Neurogenic (after head trauma/surgery)
  - Reexpansion (after pneumothorax/thoracentesis)

## *Genetics*

Multifactorial

## **RISK FACTORS**

- Cardiogenic: HTN, valvular disease, hyperlipidemia, atherosclerosis, diabetes mellitus, obesity, excessive alcohol intake, physical inactivity, dietary choices, and smoking
- Noncardiogenic: sepsis, aspiration, pneumonia, trauma, inhaled toxins, DIC

## **GENERAL PREVENTION**

Early detection and treatment of risk factors, including high blood pressure, diabetes, alcohol intake, obesity, and tobacco abuse (1)[A]

## **COMMONLY ASSOCIATED CONDITIONS**

See ÒEtiology and Pathophysiology.Ó

**DIAGNOSIS**

## HISTORY

- Past medical history
  - Underlying comorbidities, including prior heart failure or prior myocardial infarction (MI)
  - Recent trauma
  - Drug or alcohol abuse
  - Dietary or medication noncompliance
  - Recent weight gain or increasing edema
  - Recent use of negative inotropic agents (calcium channel blockers)
  - Recent use of NSAIDs (increase water retention)
- Symptoms
  - Fever or other symptoms of infection
  - Progressive dyspnea
  - Orthopnea and paroxysmal nocturnal dyspnea
  - Cough
  - Fatigue and generalized weakness
  - Pink frothy sputum
  - Chest pain

## PHYSICAL EXAM

- Vital signs: tachypnea, tachycardia, and hypoxemia. Patients may be hypotensive or hypertensive.
- General: respiratory distress, diaphoresis
- HEENT (head, eyes, ears, nose, throat): frothy oral secretions, cyanosis
- Cardiac: S<sub>3</sub> or S<sub>4</sub>, jugular venous distension, murmurs suggestive of valvular disease
- Pulmonary: crackles or wheezing
- Extremities: edema, cyanosis, mottled skin

## DIFFERENTIAL DIAGNOSIS

- COPD
- Pneumonia
- Pulmonary embolism

- Asthma/reactive airway disease
- Pneumothorax
- Cardiac tamponade
- Asphyxiant or toxic gas exposure
- Inhalational burns

## **DIAGNOSTIC TESTS & INTERPRETATION**

### ***Initial Tests (lab, imaging)***

- CBC/differential to screen for anemia or infection
- Chemistry panel to screen for acute kidney injury, hyponatremia (associated with severe heart failure), or electrolyte disturbances leading to dysrhythmias
- Troponin may be elevated from recent infarction causing acute heart failure or from myocardial ischemia secondary to elevated ventricular strain. Elevated cardiac enzymes carry a strongly negative prognosis in heart failure.
- In settings of clinical uncertainty, B-type natriuretic peptide (BNP), or N-terminal pro-BNP, can add to clinical judgment in patients with symptoms suggestive of heart failure (1,2)[A]. BNP >500 pg/mL suggests heart failure, and BNP <100 pg/mL suggests alternative causes. BNP may also be elevated due to atrial fibrillation, renal failure, severe valvular disease, or pulmonary HTN.
- Liver function tests (LFTs) to check for elevated transaminases, which can suggest hepatic congestion from heart failure or may indicate heavy alcohol use contributing to cardiomyopathy
- Drug levels (aspirin, opiates, cocaine, alcohol)
- Arterial blood gas to measure PO<sub>2</sub> and A-a gradient
- Serum lipase if suspicious for pancreatitis
- TSH if suspicious for thyrotoxicosis
- Blood/urine cultures and lactic acid if concerned for severe sepsis or septic shock
- Urinalysis to check for nephrotic syndrome or UTI
- Chest x-ray to evaluate for the following:
  - Pneumothorax
  - Cardiomegaly

- Infiltrate suggestive of pneumonia
- Increased interstitial markings, perihilar alveolar edema, or pleural effusion
- CT pulmonary angiography if concerned for pulmonary emboli
- ECG to evaluate for ischemia or dysrhythmias
- Echocardiography to assess ventricular function and size, valve function, and for presence of a pericardial effusion or wall motion abnormalities (2)[C].

## *Follow-Up Tests & Special Considerations*

Emergent echocardiography if considering cardiogenic shock, tamponade, or papillary muscle rupture

## *Diagnostic Procedures*

- If cause of pulmonary edema is unknown, a pulmonary artery catheter (or Swan-Ganz) can be inserted to measure the pulmonary artery capillary wedge pressure. A wedge pressure <18 mm Hg favors acute lung injury over cardiogenic pulmonary edema.
- Patients with new-onset or worsening heart failure (without determined cause) should have further evaluation for myocardial ischemia. The pretest probability of underlying ischemic cardiomyopathy should guide the decision on which testing modality to use (1)[C].

## **TREATMENT**

### *GENERAL MEASURES*

- Guide all treatment based on the suspected cause.
- Start with supplemental oxygen.

### *MEDICATION*

Cardiogenic pulmonary edema

---

P.883

### *First Line*

- Diuretics: reduce preload for acute cardiogenic edema; used in low doses daily for chronic heart failure to manage volume overload. If on chronic diuretics, start IV dose at or above home dose and titrate for acute cardiogenic edema. Onset is 15 to 30 minutes for IV loop diuretics. Monitor for electrolyte derangement and renal dysfunction. Use very carefully in

patients with aortic stenosis.

- Acute: furosemide 40 to 80 mg IV, torsemide 10 mg IV, or bumetanide 1 mg IV
- Chronic: furosemide 20 to 80 mg q6-8h, torsemide 20 mg/day, or bumetanide 1 mg q12h
- ACE inhibitors or angiotensin receptor blockers (ARBs): reduce afterload for systolic heart failure. Maintenance therapy may be cautiously continued during exacerbation. Avoid in acutely ill patients with hypotension, acute kidney insult, hyperkalemia, or poor diuresis. Use ARBs in patients who are ACE inhibitor-intolerant.
  - Target dose for chronic heart failure: lisinopril 20 to 40 mg/day, enalapril 10 to 20 mg q12h, captopril 50 mg q8h, candesartan 32 mg/day, valsartan 160 mg q12h, losartan 100 mg/day
- $\beta$ -Blockers: reduce afterload for systolic heart failure. Maintenance therapy may be continued for mild decompensation; hold or reduce dose for moderate to severe decompensation. Avoid if patients are hypotensive or recently received inotropic therapy. Do not initiate until recovery from acute exacerbation of heart failure.
  - Target dose for chronic heart failure: carvedilol 25 mg q12h, metoprolol ER 200 mg/day, bisoprolol 10 mg/day
- Inotropes: Improve contractility in hypotensive patients with severe systolic heart failure and signs of systemic hypoperfusion (2)[B]. Inotropes increase myocardial oxygen demand and may damage the ischemic myocardium.
  - Dobutamine: 5 to 10  $\mu$ g/kg/min IV, titrate
  - Milrinone: loading dose (optional): 50  $\mu$ g/kg IV over 10 minutes, then infuse 0.375 to 0.750  $\mu$ g/kg/min, titrate
  - Dopamine: 5 to 10  $\mu$ g/kg/min IV, titrate
  - Norepinephrine: 2 to 4  $\mu$ g/min IV for acute cardiogenic shock following acute MI; not for use in acute decompensated heart failure
- Nitrates: Acute cardiogenic pulmonary edema use IV nitrate vasodilators. Rapid onset. Nitroglycerin IV 5 to 10  $\mu$ g/min, titrate 5 to 10  $\mu$ g/min q3-5min to max 200  $\mu$ g/min until distress resolved or onset of hypotension. For severe HTN, consider IV nitroprusside 5 to 10  $\mu$ g/min, titrate. Max 400  $\mu$ g/min. Use <48 hours due to risk of cyanide toxicity.
  - For patients who are not tolerant of ACE inhibitors or ARBs, hydralazine and an oral nitrate should be started (1)[C].
- Precaution: Monitor the additive hypotensive effects of diuretics, nitrates, and afterload reducers.

## *Second Line*

- Thiazide diuretics: hydrochlorothiazide (HCTZ) 25 to 50 mg/day PO, metolazone 2.5 to 10 mg/day PO
- Spironolactone: 25 to 50 mg/day PO; recheck renal function and electrolytes in 7 to 10 days
- Digoxin: 125  $\mu$ g/day PO, titrate to serum concentration of 0.5 to 0.8 ng/mL
- Noncardiogenic pulmonary edema
  - High-altitude pulmonary edema
    - Descent is the single best treatment (3)[A].
    - Adjunctive therapy: supplemental oxygen. Consider nifedipine ER 30 mg PO q12h or sildenafil 50 mg PO q8h or tadalafil 10 mg PO q12h (3)[C].

## *ISSUES FOR REFERRAL*

- Cardiology referral for underlying cardiac disease
- Patients with ARDS should be carefully monitored in an ICU setting.

## *ADDITIONAL THERAPIES*

- Noninvasive positive pressure ventilation (NPPV) should be considered early for emergency department patients with acute respiratory distress from cardiogenic pulmonary edema/congestive heart failure (CHF). NPPV decreases preload and afterload, thereby alleviating symptoms and potentially avoiding intubation by allowing time for medications to work. Use cautiously if patients are hypotensive (4)[A].
- Early invasive ventilation should be considered for patients with noncardiogenic pulmonary edema secondary to acute respiratory distress syndrome.

## *SURGERY/OTHER PROCEDURES*

- Extracorporeal membrane oxygenation (ECMO) for severe refractory hypoxia/ARDS
- Intra-arterial balloon pump for cardiogenic shock
- Implantable cardioverter defibrillator (ICD) for sudden cardiac death prevention in patients with prior cardiac arrest or ischemic/dilated cardiomyopathy and LVEF <30% (2)[B]
- Cardiac resynchronization therapy (CRT) may be useful for LVEF  $\geq$ 35%, sinus rhythm, and QRS >0.15 m/s (2)[B].
- LV assist device (LVAD) for severe systolic dysfunction as bridge to a heart transplant (2)[B].

# INPATIENT CONSIDERATIONS

## *Admission Criteria/Initial Stabilization*

- Hypotension
- Acute kidney injury
- Altered mental status
- Dyspnea at rest
- O<sub>2</sub> saturation <90%
- Acute coronary syndromes
- Arrhythmias (i.e., new-onset atrial fibrillation)
- Mild distress: oxygen by nonrebreather mask
- Significant hypoxia
- Intubation for patients with apnea, altered mental status, or hypoxia despite NPPV

## *IV Fluids*

Use crystalloid infusions cautiously. Limit free water.

## *Nursing*

- Daily weights, strict input/output
- Assess for functional improvement.

## *Discharge Criteria*

- Underlying condition treated, fluid status optimized
- Started *β*-blocker and ACE inhibitor in patients with CHF (1)[B]
- Patient and family educated about diet/medications

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- Strict input/output measurement, daily weights
- Posthospitalization appointment in 7 to 10 days

## DIET

Low-sodium diet (<2 g/day), fluid restriction (<2 L/day) (2)[C]

## PATIENT EDUCATION

- Dietary precautions
- Early signs and symptoms of fluid overload
- Adjust diuretic dose based on recent weight gain.

## PROGNOSIS

Mortality: 30-60% for noncardiogenic edema/ARDS; up to 80% for cardiogenic causes

## COMPLICATIONS

- Acute hypoxic respiratory failure
- CHF increases long-term risk for dysrhythmias and sudden cardiac death.
- ARDS increases short-term risk for pneumonia and pneumothorax. Long-term complications include risks of pulmonary HTN and fibrosis.

Altitude Illness; Congestive Heart Failure: Differential Diagnosis; Respiratory Distress Syndrome, Acute (ARDS)

## Codes

**&NA;**

### ICD10

- J81.1 Chronic pulmonary edema
- J81.0 Acute pulmonary edema

## Clinical Pearls

**&NA;**

- Diagnosis of the underlying etiology is essential.
- Initial treatment of acute cardiogenic edema among hypertensive/normotensive patients includes IV diuretics, IV nitrates, and NPPV.
- Hypotensive patients with pulmonary edema due to CHF will require careful use of inotropes and vasopressor to improve hemodynamic stability.
- Pulmonary edema from ARDS has very high mortality and requires ICU-level care. Home dietary and medication management are critical for long-term treatment of CHF.

# Pulmonary Embolism

Karla A. Oliveros, MD

Alfonso Tafur, MD, MS, RPVI

## BASICS

### DESCRIPTION

- Pulmonary embolism (PE) is the most serious presentation of venous thromboembolism (VTE).
- Mortality exceeds 15% during the first 3 months. In 25% of patients, first manifestation is sudden death.

### EPIDEMIOLOGY

Case fatality rate 1-60%. For patients with intermediate risk, mortality rate is 3-15% if right ventricular (RV) dilation or dysfunction. If hemodynamically unstable, mortality is >15% due to worsening RV failure and cardiogenic shock.

### Incidence

- Approximately 60 to 70 per 100,000, with >100,000 cases annually in the United States.
- Incidence increases with age, most occurring at 60 to 70 years of age.
- 250,000 hospitalizations per year in the United States, 10-60% in hospitalized patients.
  - Highest risk for orthopedic patients
  - 1:1,000 pregnancies (including postpartum)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Venous stasis, endothelial damage, and changes in coagulation properties trigger formation of thrombus (1).
- Causes increased pulmonary vascular resistance, impaired gas exchange, and decreased pulmonary compliance. RV failure due to pressure overload is usually the primary cause of death (1).
- DVT in the proximal veins is the most common source of PE, up to 85% of the cases.

## Genetics

- Factor V Leiden: Most common thrombophilia. +5.5% in Caucasian, 2.2% in Hispanics, 1.2% in African American, 0.5% in Asian. Associated with 20% of all VTE
- Prothrombin G20210A: 3% of Caucasians, rare in African American, Asian, and Native American; 6% in patients with VTE
- Deficiencies in protein C, S, and antithrombin

## RISK FACTORS

- Acquired: age, immobilization, surgery, major trauma, lower limb fractures, joint replacement, spinal cord injury, cancer, hormonal replacement therapy, pregnancy/puerperium, previous thrombosis, paroxysmal nocturnal hemoglobinuria, antiphospholipid syndrome, prolonged travel
- Oral contraceptives is the most frequent medication (1).
- Inherited: Antithrombin deficiency, protein C or S deficiency, factor V Leiden, prothrombin gene mutation *G20210A* (1)

## GENERAL PREVENTION

- Mechanical thromboprophylaxis: early ambulation after surgery, compression stockings, and intermittent pneumatic compression
- Intermediate risk: general, gynecologic, or urologic surgery; prophylaxis is recommended with low-molecular-weight heparin (LMWH), unfractionated heparin (UFH), or fondaparinux.
- High risk: 10 or more days prophylaxis in hip or knee arthroplasty, with LMWH, fondaparinux, apixaban, dabigatran, rivaroxaban, or low-dose UFH. 28 to 35 days with LMWH, fondaparinux, UFH, or vitamin K antagonists (VKA) in hip fracture surgery. LMWH or UFH in major trauma, spinal cord injury
- Long-distance travel (>8 hours): hydration, walking, avoidance of constrictive clothing and frequent calf exercises; if additional risk factors, then compression stockings below knee
- Patients with factor V Leiden, prothrombin *G20210A* with no previous thrombosis do not need long-term daily prophylaxis.

## DIAGNOSIS

- Establish a pretest probability based on clinical criteria (2).
  - Wells score

- Clinical signs and symptoms of DVT +3
  - Alternative diagnosis is less likely than PE +3
  - Heart rate >100 +1.5
  - Immobilization previous 4 weeks +1.5
  - Previous DVT/PE +1.5
  - Hemoptysis +1
  - Malignancy +1
  - <2 points, low clinical probability; 2 to 6 points, moderate; >7 points, high
- Recently, Wells and revised Geneva score were simplified (2).
    - Wells score: Each predictor is +1. PE unlikely if 0 to 1, PE likely if >2.
    - Geneva score: Each predictor is +1 except for heart rate >95 which is +2. PE unlikely if 0 to 2 and PE likely if >3.

## HISTORY

- Determine if the presentation is provoked or idiopathic. Approximately 30% of cases develop without identifiable risk factor.
- Presence of risk factors and family history
- Bleeding risk (previous anticoagulation, history of bleeding, recent interventions/surgeries, liver disease)
- Sudden onset dyspnea (>85%), chest pain (>50%), cough (20%), syncope (14%), hemoptysis (7%).

## PHYSICAL EXAM

- Dyspnea, syncope, hemoptysis, tachycardia, tachypnea, accentuated S<sup>2</sup>. Pleuritic chest pain, pleural friction rub, rales (1)
- Signs of DVT, leg swelling, tenderness, visible collateral veins (1)
- Signs of RV failure: jugular vein distention, third or fourth sound, systolic murmur at left sternal edge, hepatomegaly (1)

## ALERT

- Massive PE: mortality rate exceeding 20%. Hemodynamic instability with sustained hypotension, pulselessness, or persistent bradycardia, cardiogenic shock, acute manifesting RV failure (1)

- Submassive PE: hemodynamically stable. Mortality rate of 5-25%. No systemic hypotension but there is either RV dysfunction or myocardial necrosis (1,3).
  - RV dysfunction: RV dilation or systolic dysfunction on echocardiography, RV dilation on CT, elevation of brain natriuretic peptide (BNP) or N-terminal pro-BNP (500 pg/mL), or consistent ECG changes
- Low-risk PE: acute and absence of clinical markers of adverse prognosis

## *DIFFERENTIAL DIAGNOSIS*

- Pulmonary: pneumonia, bronchitis, pneumothorax, pneumonitis, chronic obstructive pulmonary disease (COPD) exacerbation, pulmonary edema, pneumothorax
- Cardiac/vascular: myocardial infarction, pericarditis, congestive heart failure (CHF), aortic dissection
- Musculoskeletal: rib fracture(s), musculoskeletal chest wall pain

## *DIAGNOSTIC TESTS & INTERPRETATION*

- D-dimer ELISA: In patients with low pretest probability, it can rule out PE if it is negative (high negative predictive value [NPV]) (1)[A]. It is not diagnostic if positive (low positive predictive value [PPV]) and it is not helpful if pretest probability is intermediate or high (1)[B].
- CBC, creatinine, aPTT and PT, ABG: In young patients with idiopathic, recurrent, or significant family history of VTE, consider testing for hypercoagulable tests.
  - Do not test for protein C, S, factor VIII, or antithrombin in the acute setting or while on treatment, as may be falsely abnormal.
  - Patients with intermediate or high pretest probability and low probability with elevated D-dimer need further diagnostic testing.
- Chest x-ray (CXR): Westermark sign (lack of vessels in an area distal to the embolus), Hampton hump (wedge-shaped opacity with base in pleura), Fleischner sign (enlarged pulmonary arteries), atelectasis, pleural effusion, pulmonary infarct, hemidiaphragm elevation (1)
- ECG: right heart strain, nonspecific rhythm abnormalities, S1Q3T3
- CT pulmonary angiography: sensitivity 96-100%, specificity 86-89%; NPV 99.8%. If normal, it safely excludes PE if low or intermediate clinical probability (1)[A].
- Ventilation/perfusion scintigraphy (V/Q scan): safe with few allergic reactions. Use if CT angiography is not available or contraindicated. A high-probability V/Q scan makes the

diagnosis of PE; normal V/Q scan excludes PE (1)[B].

- Pulmonary angiography: gold standard but invasive and technically difficult: 2% morbidity and <0.01 mortality risk (1)[C]
- Echocardiogram: Assess RV function, found in 25% of patients with PE.
- Magnetic resonance angiography: lower sensitivity and specificity than CT angiography
- Compression venous ultrasound (CUS): noninvasive. Sensitivity >90%, specificity approximately 95%. It confirms the diagnosis of PE in patients with clinical suspicion (1)[B].
- CT venography: can be done at the same time as CT angiography; increases diagnostic yield (1)

## **ALERT**

If your preclinical probability is intermediate or high and the patient has a low bleeding risk, start treatment while waiting for the diagnostic results (3)[C].

## **Follow-Up Tests & Special Considerations**

Elevated troponin I or T and elevated BNP are markers for higher risk patients.

## **TREATMENT**

### *MEDICATION*

- If clinical suspicion is high and no contraindications, start treatment immediately.
  - Start LMWH, fondaparinux, UFH, as initial therapy for first 5 to 10 days. VKA can be started the 1st day and must overlap with parenteral treatment for minimum of 5 days, until international normalized ratio (INR) is 2 to 3 for 24 hours.
  - Following 5 to 10 days of parenteral therapy, dabigatran or edoxaban are also approved (1).
- 
- An oral option for initial and long-term treatment is rivaroxaban or apixaban (1).
  - Patients with massive PE with low bleeding risk: Consider systemic thrombolytics if no contraindications. Also in patients <75 years old with submassive PE. Greater benefit if initiated within 48 hours of symptoms onset (1)

P.885

### *First Line*

- UFH (3)[A]:
  - IV bolus of 80 U/kg or 5,000 U followed by continuous infusion (initially 18 U/kg/hr or 1,300

U/hr) with dose adjustments to maintain aPTT that corresponds to anti-Xa levels of 0.3 to 0.7

- SC injection: 2 options:
  - Monitored: 17,500 U or 250 U/kg BID with dose adjustments to maintain an aPTT that corresponds to anti-Xa levels of 0.3 to 0.7 measured 6 hours after a dose
  - Fixed dose: 333 U/kg initial dose, followed by 250 U/kg BID
- LMWH: preferred due to lower risk of major bleeding and heparin-induced thrombocytopenia (HIT) (1),(3)[A]
  - Enoxaparin (Lovenox) 1 mg/kg/dose SC q12h
  - Dalteparin (Fragmin 200 U/kg SC q24h
  - Fondaparinux (Arixtra): 5 mg (body weight <50 kg), 7.5 mg (body weight 50 to 100 kg), or 10 mg (body weight >100) SC q24h
- Maintenance therapy: Warfarin on day 1, if possible; 5 mg/day for 3 days in hospitalized or older patients, and at a dose of 10 mg in <60 years of aged patients; adjust dose to maintain an INR of 2 to 3. Needs to overlap with UFH, LMWH, or fondaparinux: 5 to 7 days, until 2 consecutive days of therapeutic INR (1).
- Rivaroxaban: 15 mg BID for 3 and then 20 mg once daily to complete treatment. Compared to warfarin, it has less major bleeding side effects while having same efficacy (1)[B].
- Edoxaban: 60 mg once daily (reduced to 30 mg once daily if CrCl 30 to 50 mL/min or body weight <60 kg). Patients require initial treatment with LMWH at least 5 days before starting edoxaban. Less bleeding risk compared to warfarin (1)[B]
- Apixaban: 10 mg BID for 7 days, followed by 5 mg once daily was compared to conventional therapy. Compared to warfarin, noninferior against recurrent symptomatic VTE or death related to VTE, with less frequently major bleeding episodes (1)[B]
- Dabigatran: Require initial treatment with LMWH. Compared to warfarin, 150 mg BID had noninferior efficacy and no differences in major bleeding and fewer episodes of any bleeding (1)[B].

## **ALERT**

### Contraindications

- Active bleeding.
- Heparin: HIT
- LMWH: HIT, renal failure

- Warfarin: pregnancy
- Rivaroxaban and Fondaparinux: renal failure (1)[A]
- Edoxaban: severe kidney or liver failure (1)[A]
- Apixaban: renal impairment and nonvalvular atrial fibrillation (1)[A]
- Dabigatran: severe kidney problems. Use of dronedarone or ketoconazole increase risk.

## *Pregnancy Considerations*

- Warfarin is teratogenic and should not be used in pregnant patients (especially in 1st trimester); safe while breastfeeding
- **LMWH**: Dalteparin, enoxaparin, and fondaparinux are Category B; heparin is Category C, use if the benefit outweighs risks.
- **UFH**: Require aPTT monitoring. Can cause osteoporosis if used for prolonged period
- Rivaroxaban is Category C.
- Edoxaban and Apixaban: Category B; increases risk of hemorrhage
- Dabigatran: Category C; use it only if benefit outweighs side effects.

## *Second Line*

Massive PE: Consider thrombolytics if the patient has hemodynamic compromise and low bleeding risk, intracranial hemorrhage risk: 0.7 to 6.4%: (1),(3)[B]

- Tissue plasminogen activator (tPA) 100 mg infused over 2 hours. Absolute contraindications:
  - Intracranial hemorrhage, known intracranial cerebrovascular or malignant disease, ischemic stroke within 3 months, suspected aortic dissection, bleeding diathesis, active bleeding, recent neurosurgery, or major trauma

## *SURGERY/OTHER PROCEDURES*

- Inferior vena cava (IVC) filter placement if absolute contraindication for anticoagulation or recurrent PE despite adequate anticoagulation treatment (3)[B].
- PREPIC2 trial showed that retrievable IVC filters at 3 months plus anticoagulation compared to anticoagulation alone among patients with severe PE had no benefit reducing the risk of symptomatic recurrent PE (3%, 95% CI, 1.1-6.5% vs. 1.5%, 95% CI, 0.3-4.3%) (3)[C].
- Emergency embolectomy can be considered in patients with massive PE with contraindications for thrombolysis (3)[C].

Consider catheter-based interventions if massive PE and thrombolytic contraindications (3)[C].

- Consider ultrasound-assisted catheter-directed thrombolysis (USAT) in patients with intermediate risk of death or submassive PE, superior than heparin alone in reversing RV dilation at 24 hours without increase in bleeding complications.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

ICU-level care if hemodynamically unstable

## **ONGOING CARE**

Duration of anticoagulation

- Provoked PE (trigger no longer present): 3 months (1)[B]
- Unprovoked PE: Minimum of 3 months, consider long-term or prolonged secondary prophylaxis if bleeding risk is low (1)[B].
- Cancer-related PE: LMWH first 3 to 6 months. Consider secondary prophylaxis as long as the patient has active cancer (1)[B].
- Recurrent PE: long-term anticoagulation

## ***FOLLOW-UP RECOMMENDATIONS***

- If concomitant DVT, knee-height compression stockings, 30 to 40 mm Hg knee height
- If an IVC filter was placed, follow-up for retrieval.

### ***Patient Monitoring***

- INR should be checked regularly; target is 2 to 3 (1).
- aPTT needs to be monitored in SC UFH (1).
- Anti-Xa can be checked in special circumstances if treated with LMWH, including pregnancy, younger patients, renal disease.

### ***DIET***

Warfarin use; recommend a vitamin K diet.

## ***PROGNOSIS***

- Massive PE 50% versus nonmassive PE 8-14%
- Simplified Pulmonary Embolism Severity Index score predicts acute mortality (any one of the following defines high-risk: age >80 years, history of cancer, chronic cardiopulmonary disease, heart rate 110/min, systolic blood pressure <100 mm Hg, O<sub>2</sub> saturation <90%) (1)[B].
- High early mortality risk: shock or hypotension, +SPESI index >1 + RV dysfunction signs by imaging and cardiac laboratory biomarkers (1)
- Intermediate high early mortality risk: no shock or hypotension + SPESI >1 + RV dysfunction signs by imaging and cardiac laboratory biomarkers (1)
- Intermediate low early mortality risk: no shock or hypotension + SPESI >1 + either RV dysfunction by imaging or cardiac laboratory biomarkers (1)
- Low early mortality risk: no shock or hypotension, no SPESI; imaging is optional (if assessed is negative) (1).

## COMPLICATIONS

- 1 in 25 patients will develop chronic thromboembolic pulmonary hypertension, recurrent DVT, or PE.
- Younger age, previous PE, and larger perfusion defect were significantly associated with increased risk of CTPH found in 5.2% of 58 patients with previous DVT, and 33.3% of 24 patients with previous PE.
- Incidence of major hemorrhage associated with thrombolytics is 8%; intracerebral bleed is 2% (fatal in 1/2 of cases).

**&NA;**

## **ICD10**

- I26.99 Other pulmonary embolism without acute cor pulmonale
- I27.82 Chronic pulmonary embolism

## **Clinical Pearls**

**&NA;**

- PE can be excluded in patients who have low pretest probability and negative D-dimer testing.
- Perform cancer-oriented review of systems and age/gender-appropriate cancer screening in patients >40, recurrent VTE, upper extremity DVT (not related to catheter or lines), bilateral lower extremity DVT, intra-abdominal DVT, resistance to treatment.
- In patients with prolonged baseline aPTT, adjust heparin dose with anti-Xa levels (therapeutic range 0.3 to 0.7).

# Pulmonary Fibrosis

Anna Rudnicki, MD

## BASICS

### DESCRIPTION

- Characterized by fibrosis of the lung parenchyma
- Chest CT shows reticular pattern and honeycombing, with subpleural and lower lobe predominance.
- Lung biopsy shows "usual interstitial pneumonia" pattern.
- Classified based on etiology
  - Idiopathic
  - Nonidiopathic

### EPIDEMIOLOGY

#### Incidence

- Incidence of IPF is 7 to 16/100,000 person-years
- Idiopathic pulmonary fibrosis (IPF) is more common in men.
- Most patients with IPF are >60 years.
- Incidence of nonidiopathic pulmonary fibrosis is unknown.

#### Prevalence

- Prevalence of IPF is 2 to 39 cases/100,000 people.
- Prevalence of nonidiopathic pulmonary fibrosis is unknown.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Postulated that microinjury to alveolar epithelial cells causes release of cytokines that activates fibroblasts, which in turn leads to excess production of extracellular matrix.
- Causes of the nonidiopathic form include:

- Occupational exposure
- Environmental exposure
- Drugs
- Systemic connective tissue diseases
- Granulomatous diseases

## *Genetics*

- <5% of IPF is familial and may involve mutations in surfactant protein A2 and C and/or abnormal telomere shortening.
- Most likely mode of transmission is autosomal dominant with variable penetrance.

## **RISK FACTORS**

- Family history of pulmonary fibrosis
- Gastroesophageal reflux disease (GERD)
- Smoking
- Exposure to birds, livestock, dust from metals or wood, solvents

## **GENERAL PREVENTION**

Avoid the risk factors mentioned earlier, such as smoking, certain occupational exposures, or drugs that induce pulmonary fibrosis.

## **COMMONLY ASSOCIATED CONDITIONS**

- Pulmonary hypertension: occurs in 30-80% of patients with IPF, likely as a result of hypoxemic vasoconstriction
- GERD
- Nonidiopathic pulmonary fibrosis may be associated with connective tissue diseases (e.g., rheumatoid arthritis and scleroderma).

## **DIAGNOSIS**

### **HISTORY**

- Slowly progressive dyspnea

## *PHYSICAL EXAM*

- Tachypnea
- Fine inspiratory crackles
- Possible clubbing

## *DIFFERENTIAL DIAGNOSIS*

- Asbestosis
- Berylliosis
- Coal worker's pneumoconiosis
- Chronic hypersensitivity pneumonitis
- Sarcoidosis
- Silicosis

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- High-resolution chest computed tomography (HRCT) is required to make diagnosis. Characteristic findings include a reticular pattern, traction bronchiectasis, and honeycombing. There is a subpleural and lower lobe predominance. There is minimal to no evidence of active inflammation (1,2).
- If the patient has characteristic findings of pulmonary fibrosis on chest CT, then lung biopsy may not necessarily be required (1).
- HRCT is needed as part of initial workup (as above).

### *Follow-Up Tests & Special Considerations*

- Surgical lung biopsy should be considered if clinical presentation and HRCT are not entirely characteristic of pulmonary fibrosis (1).
- Blood work to rule out associated collagen vascular disease (1)
- Bronchoscopy with bronchoalveolar lavage may help rule out other types of interstitial lung disease and concurrent infection (1).

## *Diagnostic Procedures/Other*

- Pulmonary function testing (PFT): initially, may see only decrease in diffusing capacity; later in disease, may develop decrease in lung volumes as well
- Echocardiogram to evaluate for concomitant pulmonary hypertension
- Resting and exercise pulse oximetry to determine need for supplemental oxygen

## *Test Interpretation*

Usual interstitial pneumonitis: shows interstitial scarring, honeycombing, and fibroblastic foci. There is temporal heterogeneity, meaning, there may be areas of normal lung adjacent to fibrosed or inflamed lung.

## **TREATMENT**

### **GENERAL MEASURES**

- Pulmonary rehabilitation (1)[C]
- Consider treating for GERD, even if asymptomatic (1)[B].
- Consider lung transplant evaluation.

### **MEDICATION**

#### *First Line*

Supplemental oxygen, if needed (1)[C]

### **ISSUES FOR REFERRAL**

- Patients should be evaluated and cared for longitudinally by a pulmonologist.
- If any uncertainty in diagnosis, then consider referral to thoracic surgery for lung biopsy (3,4).
- Depending on patient age, comorbidities, and preference, may consider referral for lung transplant.

### **ADDITIONAL THERAPIES**

- A recent study showed an increase in mortality in patients treated with a combination of prednisone, azathioprine, and *N*-acetylcysteine when compared with those receiving placebo or *N*-acetylcysteine alone (3).

- Recent studies have shown a benefit with the antifibrotic agent pirfenidone and the tyrosine kinase inhibitor nintedanib for slowing the progression of IPF (4,5). These drugs were approved by the FDA in 2014.
- Many other clinical trials are currently under way. Some of the targets being studied include TGF-*β*; connective tissue growth factor; IL-13; CCL2; CXCR4; and CXCL12, ACE, and angiotensin II (6).

## ***SURGERY/OTHER PROCEDURES***

Lung transplant carries a 5-year survival of 50-56%.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

None

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Worsening shortness of breath and/or increased oxygen requirements:

- Provide adequate supplemental oxygen.
- Workup for other possible causes of respiratory decompensation
- If no other cause for respiratory decompensation is found, then consider administration of high-dose steroids.

### ***Nursing***

Supplemental oxygen to keep saturations >90%

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Patient should follow-up with a pulmonologist

### ***Patient Monitoring***

Disease progression can be monitored by periodic PFTs and HRCT.

### ***DIET***

No specific dietary requirements

## PATIENT EDUCATION

- Patients should be counseled extensively regarding the prognosis of this diagnosis and given as much support as possible. Information about support groups in the local community and online may be helpful.
- American Lung Association: <http://www.lung.org/lung-health-and-diseases/lung-disease-lookup/pulmonary-fibrosis/>
- Pulmonary Fibrosis Foundation: <http://www.pulmonaryfibrosis.org/> which includes information about active pulmonary fibrosis clinical trials

## PROGNOSIS

- Median survival time was thought to be 2 to 3 years from time of diagnosis. However, recent data from clinical trials suggest that this may be an underestimate.
- Some patients may deteriorate quickly, whereas others can remain stable for an extended period of time. Acute exacerbations carry a high mortality, and ICU treatment (mechanical ventilation) is mostly unsuccessful.
- A higher extent of fibrosis increases the risk of death, whereas a higher percentage-predicted diffusing capacity of lung for carbon monoxide reduced the risk of death.

## COMPLICATIONS

- Respiratory failure
- Infection
- Pulmonary hypertension
- Rib fractures secondary to prolonged coughing (especially in elderly patients with decreased bone density)

**Codes**

**&NA;**

## **ICD10**

- J84.10 Pulmonary fibrosis, unspecified
- J84.112 Idiopathic pulmonary fibrosis

## **Clinical Pearls**

**&NA;**

- Pulmonary fibrosis can usually be diagnosed based on characteristic chest CT findings, which include a reticular pattern, traction bronchiectasis, and honeycombing with a peripheral and basilar predominance.
- There are idiopathic and nonidiopathic forms of pulmonary fibrosis.
- Treatment options for pulmonary fibrosis are very limited and, at best, serve to slow the progression of disease.

# PYELONEPHRITIS

Katelin M. Lisenby, PharmD

Dana G. Carroll, PharmD, BCPS, CDE

Catherine Scarbrough, MD

## BASICS

### DESCRIPTION

- Acute pyelonephritis is a syndrome caused by an infection of the renal parenchyma and renal pelvis, often producing localized flank/back pain combined with systemic symptoms, such as fever, chills, and nausea. It has a wide spectrum of presentation, from mild illness to septic shock.
- Chronic pyelonephritis is the result of progressive inflammation of the renal interstitium and tubules, due to recurrent infection, vesicoureteral reflux, or both.
- Pyelonephritis is considered uncomplicated if the infection is caused by a typical pathogen in an immunocompetent patient who has normal urinary tract anatomy and renal function.
- System(s) affected: renal; urologic
- Synonym: acute upper urinary tract infection (UTI)

### Geriatric Considerations

- May present as altered mental status; absence of fever is common in this age group.
- Elderly patients with diabetes and pyelonephritis are at higher risk of bacteremia, longer hospitalization, and mortality.
- The high prevalence of asymptomatic bacteriuria in the elderly makes the use of urine dipstick less reliable in diagnosing UTI in this population (1)[A].

### Pregnancy Considerations

- Most common medical complication requiring hospitalization
- Affects 1-2% of all pregnancies. Morbidity does not differ between trimesters.
- Urine culture as test of cure 1 to 2 weeks after therapy

## *Pediatric Considerations*

- UTI is present in  $\div$ 5% of patients age 2 months to 2 years with fever and no apparent source on history and physical exam.
- Treatment (oral or IV; inpatient or outpatient) should be based on the clinical situation and patient toxicity.

## **EPIDEMIOLOGY**

### *Incidence*

Community-acquired acute pyelonephritis: 28/10,000/year

### *Prevalence*

Adult cases: 250,000/year, with 200,000 hospitalizations

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- *Escherichia coli* (>80%)
- Other gram-negative pathogens: *Proteus*, *Klebsiella*, *Serratia*, *Clostridium*, *Pseudomonas*, and *Enterobacter*
- *Enterococcus*
- *Staphylococcus*: *Staphylococcus epidermis*, *Staphylococcus saprophyticus* (number 2 cause in young women), and *Staphylococcus aureus*
- *Candida*

## **RISK FACTORS**

- Underlying urinary tract abnormalities
- Indwelling catheter/recent urinary tract instrumentation
- Nephrolithiasis
- Immunocompromise, including diabetes
- Elderly, institutionalized patients (particularly women)
- Prostatic enlargement
- Childhood UTI
- Acute pyelonephritis within the prior year
- Frequency of recent sexual intercourse/spermicide use

- New sex partner within the prior year
- Stress incontinence in the previous 30 days
- Pregnancy
- Hospital-acquired infection
- Symptoms >7 days at time of presentation

## **COMMONLY ASSOCIATED CONDITIONS**

- Indwelling catheters
- Renal calculi
- Benign prostatic hyperplasia

## **DIAGNOSIS**

### **HISTORY**

- In adults
  - Fever
  - Flank pain
  - Nausea ± vomiting
  - Malaise, anorexia
  - Myalgia
  - Dysuria, urinary frequency, urgency
  - Suprapubic discomfort
  - Mental status changes (elderly)
- In infants and children
  - Fever
  - Irritability and poor feeding
  - GI symptoms

### **PHYSICAL EXAM**

- In adults
  - Fever:  $^{38}iC$  ( $100.4iF$ )

Costovertebral angle tenderness

- Presentation ranges from no physical findings to septic shock.
  - Mental status changes common in the elderly
  - A pelvic exam may be necessary in female patients to exclude pelvic inflammatory disease.
- In infants and children
    - Sepsis
    - Fever
    - Poor skin perfusion
    - Inadequate weight gain/weight loss
    - Jaundice to gray skin color

## *DIFFERENTIAL DIAGNOSIS*

- Obstructive uropathy
- Acute bacterial pneumonia (lower lobe)
- Cholecystitis
- Acute pancreatitis
- Appendicitis
- Perforated viscus; aortic dissection
- Pelvic inflammatory disease; ectopic pregnancy
- Kidney stone
- Diverticulitis

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Urinalysis: pyuria ± leukocyte casts, hematuria, nitrites (sensitivity 35-85%; specificity 92-100%), and mild proteinuria
- Urine leukocyte esterase positive (sensitivity 74-96%; specificity 94-98%)
- Urine Gram stain; urine culture (>100,000 colonyforming units/mL or >100 colony forming units/mL + symptoms) and sensitivities
- CBC, BUN, Cr, GFR, and pregnancy test (if indicated)

- C-reactive protein levels have been shown to correlate with prolonged hospitalization and recurrence; serum albumin <3.3 g/dL also associated with risk for hospital admission.
- Imaging not necessary in routine cases
- Pediatrics: Recent guidelines recommend renal/bladder US, (not voiding cystourethrogram) after first UTI.

### *Follow-Up Tests & Special Considerations*

- Catheterization/suprapubic aspirate should be used to obtain samples from non-toilet-trained children.
- In some geriatric patients catheterization may also be necessary.
- Blood culture(s): indicated in diagnostic uncertainty, immunosuppression, or a suspected hematogenous source
- Recent antibiotic use may alter lab results.
- If patient's condition does not improve within 72 hours or if obstruction/anatomic abnormality suspected, consider:
  - CT scan of abdomen and pelvis ± contrast
  - US of kidneys, ureter, bladder
  - Cystoscopy with ureteral catheterization

### *Test Interpretation*

- Acute: abscess formation with neutrophil response
- Chronic: fibrosis with reduction in renal tissue

## **TREATMENT**

- 7 days or less of treatment is equivalent to longer treatment regimens in adult patients (including those with bacteremia) without urogenital abnormalities (2)[A].
- IV antibiotics are indicated for inpatients who are toxic or unable to tolerate oral antibiotics.

## **GENERAL MEASURES**

- Broad-spectrum antibiotics initially, tailor therapy to culture and sensitivity results
- Analgesics and antipyretics

- Consider urinary analgesics (e.g., phenazopyridine 200 mg q8h) for dysuria.

## MEDICATION

- For empiric oral therapy, a fluoroquinolone is recommended. Should fluoroquinolone resistance exceed 10% or the patient have nausea/vomiting, a single initial IV dose of a long-acting antibiotic such as ceftriaxone 1 g is additionally recommended.
- For parenteral therapy, fluoroquinolone, aminoglycoside ± ampicillin, an extended-spectrum cephalosporin or an extended-spectrum penicillin with or without an aminoglycoside, or a carbapenem are recommended.
- Contraindications:
  - Known drug allergy
  - Fluoroquinolones are not recommended in children, adolescents, and pregnant women unless other alternatives are not available.
  - Nitrofurantoin does not achieve reliable tissue levels for treatment of pyelonephritis.
- Precautions
  - Most antibiotics require adjustments in dosage for patients with renal insufficiency.
  - Monitor aminoglycoside levels and renal function.

P.889

- If *Enterococcus* is suspected based on Gram stain, ampicillin ± gentamicin is a reasonable empiric choice, unless patient is penicillin-allergic; then use vancomycin. If outpatient, add amoxicillin to fluoroquinolone, pending culture results and sensitivity. Do not use a third generation cephalosporin for suspected/proven enterococcal infections.
- >20% *E. coli* strains are resistant to ampicillin and TMP-SMX in community-acquired infections.

## First Line

- Adults
  - Oral (initial outpatient treatment)
    - Ciprofloxacin: 500 mg q12h for 7 days
    - Ciprofloxacin XR: 1,000 mg/day for 7 days
    - Levofloxacin: 750 mg/day for 5 days
  - Trimethoprim-sulfamethoxazole (TMP-SMX) (160/800 mg): 1 tab q12h for 14 days provided

uropathogen known to be susceptible ± ceftriaxone 1 g initial IV dose given IV (assuming normal creatinine clearance [CrCl])

- Ciprofloxacin: 400 mg q12h
- Levofloxacin: 750 mg/day
- Cefotaxime: 1 g q8-12h up to 2 g q4h
- Ceftriaxone: 1 to 2 g/day
- Cefepime: 1 to 2 g q12h
- Gentamicin: 5 to 7 mg/kg of body weight daily
- Ampicillin: 2 g q6h ± gentamicin for *Enterococcus*
- Severe illness: IV therapy until afebrile 24 to 48 hours and tolerating oral hydration and medications, then oral agents to complete up to a 2-week course.
- Pediatric
  - Oral: cefdinir: 14 mg/kg/day for 10 to 14 days; ceftibuten 9 mg/kg/day for 10 to 14 days; cefixime 8 mg/kg/day for 10 to 14 days
  - IV (general indication for IV therapy is age <2 months or clinical concern in other ages)
    - Ceftriaxone: 75 mg/kg/day (also can be used IM in outpatient setting)
    - Cefotaxime: 150 mg/kg/day divided in 3 to 4 doses
    - Ampicillin: 100 mg/kg/day divided in 4 doses + gentamicin 7.5 mg/kg/day divided in 3 doses

## Second Line

### Adults

- Oral
  - Oral *&bgr*-lactams should be used with caution to treat pyelonephritis due to inferior efficacy and higher relapse rates; if used, provide an initial IV dose of ceftriaxone or a consolidated 24-hour dose of an aminoglycoside and longer courses of therapy (10 to 14 days) recommended.
  - Cefpodoxime (Proxetil): 200 mg q12h
  - Amoxicillin-clavulanate: 875/125 mg q12h or 500/125 mg q8h
- IV

- Piperacillin-tazobactam: 3.375 g q6-8h
- Ticarcillin-clavulanate: 3.1 g q4-6h
- Meropenem: 500 mg q12h

## *Pediatric Considerations*

- Children <2 years of age and children with febrile or recurrent UTI are usually treated for 10 to 14 days.
- Initial empiric antibiotic choice should cover *E. coli*. Add ampicillin if *Enterococcus* is suspected.
  - Oral antibiotics (ceftibuten, cefixime, and amoxicillin/clavulanic acid) may be used alone, *or*
  - IV antibiotics (single daily dosing if an aminoglycoside is chosen) for 2 to 4 days, followed by oral antibiotics for a total of 10 to 14 days (3)[A]
- Complete outpatient antibiotic course in entirety

## *ISSUES FOR REFERRAL*

- Acute pyelonephritis unresponsive to therapy
- Chronic pyelonephritis
- Abnormal urogenital anatomy

## *SURGERY/OTHER PROCEDURES*

Perinephric abscess may require surgical drainage.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Inpatient therapy for severe illness (e.g., high fevers, severe pain, marked debility, intractable vomiting, inability to tolerate oral intake, possible sepsis), risk factors for complicated pyelonephritis, pregnancy, or extremes of age
- Outpatient therapy if mild to moderate illness (not pregnant, no nausea/vomiting; fever and pain not severe), uncomplicated, and tolerating oral hydration and medications. Many patients can be treated as outpatients.

### *IV Fluids*

As indicated for dehydration or renal calculi

## *Discharge Criteria*

Discharge on oral agent after patient is afebrile 24 to 48 hours to complete up to 2 weeks of therapy.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Women: Routine follow-up cultures not recommended unless symptoms recur after 2 weeks; then, urologic evaluation is necessary.
- Men, children, adolescents, patients with recurrent infections, patients with risk factors: repeat cultures 1 to 2 weeks after completing therapy; urologic evaluation after first episode of pyelonephritis and with recurrences

### *Patient Monitoring*

- No response within 48 hours (5% of patients): Reevaluate and review cultures, CT scan, or US to review anatomy; adjust therapy as needed; urologic consult. The two most common causes of failure to respond are a resistant organism and nephrolithiasis.
- Work with parents to monitor response in children.

### *DIET*

Encourage fluid intake.

### *PROGNOSIS*

95% of treated patients respond within 48 hours.

### **COMPLICATIONS**

- Kidney abscess
- Metastatic infection: skeletal system, endocardium, eye, meningitis with subsequent seizures
- Septic shock and death
- Acute/chronic renal failure

## Codes

### &NA;

## ICD10

- N12 Tubulo-interstitial nephritis, not spcf as acute or chronic
- N10 Acute tubulo-interstitial nephritis
- N11.9 Chronic tubulo-interstitial nephritis, unspecified

## Clinical Pearls

### &NA;

- Pyelonephritis can present with isolated confusion or mental status changes (no fever) in the elderly.
- The most common causes of poor response to treatment are antibiotic resistance and coexisting nephrolithiasis.
- Fluoroquinolones are the initial drugs of choice. for treating pyelonephritis. Oral *&bgr;-*lactams are less effective.

# Pyloric Stenosis

Joshua Scott Will, DO

Jennifer M. Cornwell, DO

Rachel M. Jones, DO

## BASICS

### DESCRIPTION

- Progressive narrowing of the pyloric canal, occurring in infancy
- Synonym(s): infantile hypertrophic pyloric stenosis (IHPS)

### EPIDEMIOLOGY

- Predominant age: infancy
  - Onset usually at 3 to 6 weeks of age; rarely in the newborn period or as late as 5 months of age
- Considered the most common condition requiring surgical intervention in the 1st year of life
- A recent decline in its incidence has been reported in a number of countries.
- Predominant sex: male > female (4 to 5:1)

### Incidence

In Caucasian population, 2 to 5:1,000 babies; less common in African American and Asian populations

### Prevalence

National prevalence level is 1 to 2:1,000 infants, ranging from 0.5 to 4.21:1,000 live births.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Abnormal relaxation of the pyloric muscles leads to hypertrophy.
- Redundant mucosa fills the pyloric canal.
- Gastric outflow is obstructed, leading to gastric distension and vomiting.

- The exact cause remains unknown, but multiple genetic and environmental factors have been implicated (1,2)[B].
- Breast versus bottle feeding—increased vasoactive intestinal peptide in breast milk may mediate pyloric relaxation and increase gastric emptying while bottle feeding may cause higher serum levels associated with pylorospasm (3)[C].

## *Genetics*

Recent studies have identified linkage to chromosome 11 and multiple loci and chromosome 16 (1,2)[B].

## **RISK FACTORS**

- Incidence higher in firstborn Caucasian boys (lower incidence in African Americans and Asians)
- 5 times increased risk with affected first-degree relative
- Strong familial aggregation and >80% heritability
- Multiple gestation—200 fold increased risk if monozygotic twin diagnosed and 20 fold increased risk if dizygotic twin diagnosed
- Breast feeding protective versus bottle feeding risk increased
- Postnatal macrolide use (i.e., erythromycin, azithromycin)—erythromycin agonist of motilin which might cause continuous contraction of the pyloric muscle (2)[B],(3)[C]
- A recent surveillance study of a population-based birth defects registry identified association between pyloric stenosis and the use of fluoxetine in the 1st trimester, even after adjustment for maternal age and smoking. The adjusted odds ratio was 9.8 (95% CI 1.5-62) (4)[B].

## **COMMONLY ASSOCIATED CONDITIONS**

Associated anomalies present in ÷4-7% of infants with pyloric stenosis.

- Hiatal and inguinal hernias (most commonly)
- Other anomalies include the following:
  - Congenital heart disease
  - Esophageal atresia
  - Tracheoesophageal fistula
  - Renal abnormalities
  - Turner syndrome and trisomy 18
  - Cornelia de Lange syndrome

- Smith-Lemli-Opitz syndrome
- A common proposed genetic link between breast cancer, endometriosis, and pyloric stenosis has been observed in families.

## DIAGNOSIS

### HISTORY

- Nonbilious projectile vomiting after feeding, increasing in frequency and severity
- Emesis may become blood-tinged from vomiting-induced gastric irritation.
- Hunger due to inadequate nutrition
- Decrease in bowel movements
- Weight loss

### PHYSICAL EXAM

- Firm, mobile (OolivelikeO) mass palpable in the right upper quadrant (historically 70-90% of the time)
- However, this finding has decreased in occurrence to about 13% due to earlier diagnosis with US (3)[C]
- Epigastric distention
- Visible gastric peristalsis after feeding
- Late signs: dehydration, weight loss
- Rarely, jaundice when starvation leads to decreased glucuronyl transferase activity resulting in indirect hyperbilirubinemia

### DIFFERENTIAL DIAGNOSIS

- Inexperienced or inappropriate feeding
- GERD
- Gastritis
- Congenital adrenal hyperplasia, salt-losing
- Pylorospasm
- Gastric volvulus

- Antral or gastric web

## **DIAGNOSTIC TESTS & INTERPRETATION**

Metabolic disturbances are late findings and are uncommon in present era of early diagnosis and intervention.

- If prolonged vomiting, then check electrolytes for the following:
  - Hypokalemia
  - Hypochloremia
  - Metabolic alkalosis
- Elevated unconjugated bilirubin level (rare)
- Paradoxical aciduria: The kidney tubules excrete hydrogen to preserve potassium in face of hypokalemic alkalosis.
- Abdominal US is the study of choice.
  - US shows thickened and elongated pyloric muscle and redundant mucosa.
- Upper GI series reveals strong gastric contractions; elongated, narrow pyloric canal (string sign); and parallel lines of barium in the narrow channel (double-tract sign or railroad track sign).

### *Test Interpretation*

Concentric hypertrophy of pyloric muscle

---

P.891

## **TREATMENT**

### **SURGERY/OTHER PROCEDURES**

- Ramstedt pyloromyotomy is curative. The entire length of hypertrophied muscle is divided, with preservation of the underlying mucosa.
- Surgical approaches include open (traditional right upper quadrant transverse) incision, more contemporary circumumbilical incision, and laparoscopic techniques.
- A recent review concluded that the laparoscopic approach results in less postoperative pain and can be performed with no increase in operative time or complications (5)[A].
- Conservative approach

- Conservative management of infantile hypertrophic pyloric stenosis with atropine can be effective in approximately six out of seven cases but has a lower success rate and longer duration of therapy than surgery (6)[B].
- Atropine therapy may be considered as an alternative to pyloromyotomy for patients unsuitable or at high risk for surgery and in areas of the world where surgery on small infants is unavailable or unsafe (6)[B].

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Prompt treatment to avoid dehydration and malnutrition
- Correct acid-base and electrolyte disturbances. Surgery should be delayed until alkalosis is corrected.
- Patients need pre- and postop apnea monitoring. They have a tendency toward apnea to compensate with respiratory acidosis for their metabolic alkalosis.

### *IV Fluids*

To correct dehydration and metabolic abnormalities. For optimal resuscitation in infants, use D5 1/2NS with 20 meq of KCl (3)[C].

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Routine pediatric health maintenance
- Postoperative monitoring, including monitoring for pain, emesis, apnea
- If significant emesis present after 1 to 2 weeks, then upper GI studies needed to rule out incomplete pyloromyotomy or duodenal leak (3)[C]

#### *DIET*

- No preoperative feeding
- Initiate feeding 4 hours after surgery with adlib feedings thereafter (7)[A].

# PROGNOSIS

Surgery is curative.

## COMPLICATIONS

- No long-term morbidity
- Incomplete pyloromyotomy
- Mucosal perforation
- Wound infections
- Delayed feeding due to postoperative vomiting
- Serosal tear
- Subcutaneous emphysema
- 4.6-12% complication rate (3)[C]

## Codes

&NA;

### ICD10

Q40.0 Congenital hypertrophic pyloric stenosis

## Clinical Pearls

&NA;

- Pyloric stenosis is the most common condition requiring surgical intervention in the 1st year of life.
- The condition classically presents between 1 and 5 months of life, with projectile vomiting after feeds and a firm, mobile mass in the right upper quadrant.
- Abdominal US is the study of choice.
- Surgery (laparoscopic Ramstedt pyloromyotomy is the preferred method) is curative.

# Rabies

Alan M. Ehrlich, MD

## BASICS

### DESCRIPTION

- A rapidly progressive CNS infection caused by a ribonucleic acid (RNA) rhabdovirus affecting mammals, including humans
- Generally considered to be 100% fatal once symptoms develop
- System(s) affected: nervous
- Synonym(s): hydrophobia (inability to swallow water)

### EPIDEMIOLOGY

#### Incidence

- Most cases are in developing countries.
- Estimated 55,000 deaths worldwide per year
- Typically only 1 to 3 cases per year in the United States, with 1/3 of those being due to exposure outside of the United States
- Predominant age: any
- Predominant sex: male = female

### ETIOLOGY AND PATHOPHYSIOLOGY

*Lyssavirus*, an RNA virus in the family *Rhabdoviridae*

- Rabies virus is a neurotropic virus present in saliva of infected animals.
- Transmission occurs via bites from infected animals or when saliva from an infected animal comes in contact with an open wound or mucous membranes.
- Bats are most common reservoir in the United States.

### RISK FACTORS

- Professions or activities with exposure to potentially infected (wild or domestic) animals (e.g., animal handlers, lab workers, veterinarians, cave explorers)
- Most U.S. cases are associated with bat exposure.
- Internationally, rabies is widespread in both domestic and feral dogs.
- Human-to-human transmission has occurred through transplantation of cornea, solid organs, and other tissues.
- Travel to countries where canine rabies is endemic.

## GENERAL PREVENTION

- Preexposure vaccination for high-risk groups (veterinarians, animal handlers, and certain laboratory workers)
- Consider preexposure vaccination for travelers to areas (such as North Africa) that have increased risk of rabies from domestic animals.
- Immunization of dogs and cats
- Contact animal control and avoid approaching or handling wild (or domestic) animals exhibiting strange behaviors.
- Avoid wild and unknown domestic animals.
- Seek treatment promptly if bitten, scratched, or in contact with saliva from potentially infected animal.
- Prevent infection by prompt postexposure treatment.
- Consider postexposure prophylaxis for individuals in direct contact with bats, unless it is known that an exposure did not occur.
- Hospital contacts of patients infected with rabies do not require postexposure prophylaxis unless there has been exposure through mucous membranes or an open wound (including a bite) to saliva, CSF, or brain tissue from the infect patient.

## DIAGNOSIS

### HISTORY

- History of animal exposure
- Most patients do not recall exposure.
- Five stages (may overlap)
  - Incubation period: time between bite and first symptoms: usually 10 days

to 1 year (average of 20 to 60 days). Incubation is shortest in patients with extensive bites in the head or trunk.

- Prodrome: lasts 1 to 14 days; symptoms include pain or paresthesia at bite site and nonspecific flulike symptoms, including fever and headache.
- Acute neurologic period: lasts 2 to 10 days. CNS symptoms dominate; generally 1 of 2 forms: (i) furious rabies: brief (~5 minute) episodes of hyperactivity with hydrophobia, aerophobia, hyperventilation, hypersalivation, and autonomic instability; (ii) paralytic rabies: Paralysis dominates; may be ascending (as in Guillain-Barré syndrome) or may affect 1 limbs differentially
- Coma: lasts hours to days; may evolve over several days following acute neurologic period; may be sudden, with respiratory arrest
- Death: usually occurs within 3 weeks of onset as result of complications

## **PHYSICAL EXAM**

Findings range from normal exam to severe neurologic findings, including paralysis and coma, depending on the stage of rabies at the time of presentation.

## **DIFFERENTIAL DIAGNOSIS**

- Any rapidly progressive encephalitis; important to exclude treatable causes of encephalitis, especially herpes
- Transverse myelitis

## **DIAGNOSTIC TESTS & INTERPRETATION**

### ***Initial Tests (lab, imaging)***

- Lumbar puncture. WBC count is normal or shows moderate pleocytosis; protein normal or moderately elevated
- Skin biopsy to detect rabies antigen in hair follicles
  - Available through state and federal reference labs
- Rabies antibody titer of serum and CSF
- Skin biopsy from nape of neck for direct fluorescent antibody examination
- Viral isolation from saliva or CSF
- Corneal smear stains are positive by immunofluorescence in 50% of patients.

- Hyponatremia is common.
- Head CT scan: normal or nonspecific findings consistent with encephalitis
- MRI can help rule out other forms of encephalitis.

## *Follow-Up Tests & Special Considerations*

Submit brain of the biting animal for testing if possible.

## *Test Interpretation*

Encephalitis may be found on brain biopsy. Other abnormal findings (e.g., brainstem, midbrain, cerebellum) often found only postmortem.

## **TREATMENT**

Thorough wound cleansing with soap and water is first line of treatment. Irrigate wound with virucidal agent, such as povidone-iodine, if available.

## **GENERAL MEASURES**

- Evaluate risk based on exposure and consult public health officials about the need for rabies prophylaxis.
- In the United States, raccoons, skunks, bats, foxes, and coyotes are the animals most likely to be infected. Any carnivore can carry the disease.
- Before initiating antirabies treatment, consider:
  - Type of exposure (bite or nonbite)
  - Epidemiology of rabies in species involved
  - Circumstances surrounding exposure (provoked vs. unprovoked bite)
  - Vaccination status of offending animal

## **MEDICATION**

### **ALERT**

- Immunosuppression alters immunity after vaccination. Immunosuppressive drugs should be avoided during postexposure prophylaxis if possible. If postexposure prophylaxis is given to an immunosuppressed patient, check serum samples for the presence of rabies virus-neutralizing antibody to assess response to vaccination (1)[C].

- Clean wounds thoroughly, regardless of postexposure prophylaxis status.
- Assess need for postexposure prophylaxis based on circumstances of possible exposure.
- Increased risk:
  - Bites involving skin puncture are high risk; saliva exposure is a risk only if it comes in contact with an open wound or mucous membranes.
  - Wild or domestic animals unavailable for quarantine
  - Bat exposure
  - Hybrid animals of wild and domestic species (e.g., wolf-dog)
  - Unprovoked attack (Feeding a wild animal is considered a provoked attack.)

P.893

- Management:
  - Bites from cats, dogs, and ferrets that can be watched for 10 days do not require prophylaxis unless animal shows signs of illness.
  - Skunks, foxes, bats, raccoons, and most carnivores are high risk, and prophylaxis should begin promptly unless animal can be captured and euthanized for pathologic evaluation.
  - For rodents or livestock, consult local public health authorities before initiating prophylaxis.
- Postexposure prophylaxis (2)[B]
  - Passive vaccination: rabies immunoglobulin (RIG, HyperRAB) 20 IU/kg administered once. Infiltrate RIG around the wound if possible. Administer remaining RIG IM. Do not administer RIG using the same syringe or into the same anatomic site as vaccine.
  - Active vaccination: rabies vaccine, human diploid cell vaccine (HDCV) or rabies vaccine adsorbed (RVA) or purified chick embryo cell vaccine IM in the deltoid. Give the first dose, 1 mL, as soon as possible after exposure. The day of the first dose is designated day 0. Give additional 1-mL doses on days 3, 7, and 14. If immunocompromised, give fifth dose on day 28. For children, use the anterolateral aspect of the thigh and avoid the gluteal area.
- For previously vaccinated patients, administer an initial 1-mL IM dose of vaccine immediately and an additional 1-mL dose 3 days later. RIG is not necessary in these patients (2)[B].
- Preexposure vaccination: for people in high-risk groups, such as

veterinarians, animal handlers, certain laboratory workers, and those spending time in foreign countries where rabies is enzootic (3)[B]:

- Primary preexposure: three IM 1-mL injections of HDCV or RVA in deltoid area on days 0, 7, and 21, or 28
- Preexposure boosters: For people at risk of exposure to rabies, test serum every 2 years. Administer preexposure booster of 1-mL IM if immunity is waning. If titer cannot be obtained, a booster can be administered instead.
- Contraindications: none for postexposure treatment

## *Pregnancy Considerations*

- Pregnancy is not a contraindication to postexposure prophylaxis.
- Rabies vaccination is not associated with a higher incidence of spontaneous abortion, premature births, or fetal abnormalities.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Clinical rabies

- Comfort care and sedation for all patients.
- Milwaukee protocol: experimental treatment using ketamine, midazolam, and amantadine (originally included ribavirin but no longer recommended) (1,4)[C]. One patient who did not receive pre- or postexposure prophylaxis recovered from clinical rabies in 2004 after being treated with medically induced coma and amantadine I (1)[C].
- Control cerebral artery vasospasm (with an agent such as nimodipine) (4,5)[C].
- Fludrocortisone and hypertonic saline if needed to maintain normal sodium level (5)[C]

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

After primary vaccination, serologic testing is necessary only if the patient has a disease or takes immunosuppressive medication.

### *PATIENT EDUCATION*

Use screens over ventilation areas in the roof to secure from bats. Avoid exposure to wild

mammalian species known to carry rabies and report potential exposures immediately.

## PROGNOSIS

- No postexposure failures in the United States since the 1970s.
- If untreated, rabies has the highest case fatality rate of any infectious disease; generally considered to be 100% fatal once symptoms develop.
- There have only been a small number of cases of successful recovery from rabies. Almost all received some form of pre- or postexposure immunization.

## COMPLICATIONS

0.6% of people develop mild serum sickness reaction following HDCV boosters. Mild local and systemic reactions are common following vaccination. Do not interrupt immunization series with mild reactions.

Bites, Animal and Human

## Codes

&NA;

### ICD10

- A82.9 Rabies, unspecified
- Z20.3 Contact with and (suspected) exposure to rabies

## Clinical Pearls

&NA;

- Rabies is rare in the United States but more common in other areas of the world.
- Seek immediate treatment if exposed to scratch, bite, or saliva of potentially infected animal (e.g., feral dog, bat, fox, raccoon, or other wild mammals).
- Postexposure prophylaxis consists of three steps: local wound cleansing, passive immunization

with rabies immunoglobulin, and active immunization with HDCV.

- Consider postexposure prophylaxis for those reporting direct contact with bats, unless it can be verified that an exposure did not occur.

# Rape Crisis Syndrome

Ravin V. Patel, MD

Dustin Creech, MD

## BASICS

### DESCRIPTION

- Definitions (legal definitions may vary from state to state)
  - Sexual contact: intentional touching of a person's intimate parts (including thighs) or the clothing covering such areas, if it is construed as being for the purpose of sexual gratification
  - Sexual conduct: vaginal intercourse between a male and female, or anal intercourse, fellatio, or cunnilingus between persons, regardless of sex
  - Rape (which is a legal term, physician should use the phrase alleged sexual assault): any sexual penetration, however slight, using force or coercion against the person's will
  - Sexual imposition: similar to rape but without penetration or the use of force (i.e., nonconsensual sexual contact, stalking)
  - Gross sexual imposition: nonconsensual sexual contact with the use of force
  - Corruption of a minor: sexual conduct by an individual age <sup>3</sup>18 years with an individual < 16 years of age
- Most states have expanded rape statutes to include marital rape, date rape, and shield laws.
- System(s) affected: nervous; reproductive; GI

### EPIDEMIOLOGY

- In the United States, 25% of women and 7.6% of men report being target of the definition of rape crisis syndrome listed above. The cost of this are estimated to exceed \$5.8 billion annually.
- Anyone can be sexually assaulted, but some populations are especially vulnerable.
  - Adolescents and young children
  - People with disabilities

- Elderly
- Low socio-economic status and homeless people
- Sex workers
- Those living in institutions/areas of conflict
- Predominant age
  - The incidence of sexual assault peaks in those 16 to 19 years of age, with the mean occurring at 20 years of age
    - Adolescent sexual assault has a greater frequency of anogenital injuries.
- Predominant sex: female > male
  - For males
    - 69% of male victims were first raped before age 18 years.
    - 41% of male victims were raped before age 12 years.

## *INCIDENCE*

- In the United States, approximately 1.5 million women and 834,700 men are sexually assaulted annually (1).
- Estimated that only a fraction of sexual assaults are reported to law enforcement.
- 18% of American women will be sexually assaulted during their lifetime (2).
  - Between 20% and 25% of females will experience rape/attempted rape during their college years.
- 2-3% of American men will be sexually assaulted during their lifetime.
- Most rape victims either know or have some acquaintance with their attacker.

## *RISK FACTORS*

- Chronologic age of adolescent and young adults 16 to 24 years incur sexual assault. Children living in household of sexual assault are increase risk of maltreatment and lifelong poor health.
- Previous history of victimization (sexually or physically)
- Alcohol consumption is estimated to be involved in 1/2 of sexual assault.
- Illicit drug may also contribute to sexual assault.

## GENERAL PREVENTION

- The public health approach should include both prevention and avoidance of vulnerability factors and implementation of protective factors.
- Females may benefit from assertiveness training and self-defense training.
- U.S. Preventive Services Task Force found insufficient evidence to support general screening in all their patient (no evidence of harm in screening), but physician should discuss sexual assault and family violence with their patient in nonjudgement manner.

## DIAGNOSIS

- In adults
  - History of sexual penetration
  - Sexual contact/conduct without consent and/or with the use of force
- In children
  - Actual observation/suspicion of sexual penetration, sexual contact, or sexual conduct
  - Signs include evidence of the use of force and/or evidence of sexual contact (e.g., presence of semen and/or blood).

## HISTORY

- Avoid questioning that implies the patient is at fault.
- Record answers in patient's own words insofar as possible. Include date, approximate time, and general location as best as possible. Document physical abuse other than sexual. Describe all types of sexual contact, whether actual/attempted. Take history of alcohol and/or drug use before or after alleged incident; note that some states require specific forms for documenting history.
- Document time of last activity that could possibly alter specimens (e.g., bath, shower, douche).
- Thorough gynecologic history is mandatory, including last menstrual period, last consenting sexual contact, contraceptive practice, and prior gynecologic surgery (3)[C].

## PHYSICAL EXAM

- Use of drawings and/or photographs is encouraged; note that some states require specific

forms for documenting physical exam.

- Document all signs of trauma/unusual marks.
- Document mental status/emotional state.
- Use UV light (Wood lamp) to detect seminal stains on clothing/skin.
- Obtaining the patient's consent at each step of examination helps the patient regain a sense of control.

## **ALERT**

- A forensic kit or "rape kit" contains swabs that are collected from the vagina and rectum, and instructions are given with the kit regarding proper collection.
- Many states and emergency departments across the country are using a Sexual Assault Nurse Examiner (SANE) when available. This has led to more consistent and more accurate collection of evidence in alleged rape cases.
- Complete genital-rectal exam, including evidence of trauma, secretions, or discharge.
  - Use of a nonlubricated, water-moistened speculum is mandatory because commonly used lubricants may destroy evidence.
  - Testing and/or specimen collection, as indicated, and in compliance with state requirements (4)

## **DIFFERENTIAL DIAGNOSIS**

Consenting sex among adults

## **DIAGNOSTIC TESTS & INTERPRETATION**

- In females, obtain a serum or urine pregnancy test.
- Record results of wet mount, screening for vaginitis, but also note the presence/absence of sperm and, if present, whether it is motile/immotile.
- Drug/alcohol testing as indicated by history and/or physical findings

## **TREATMENT**

## **GENERAL MEASURES**

- Providing health care to victims of sexual assault/abuse requires special sensitivity and privacy.

- All such cases *must* be reported immediately to the appropriate law enforcement agency.
- With the victim's permission, enlist the help of personnel from local support agencies (e.g., rape crisis center). When available, use of in-house social services is extremely helpful to victim and family.
- SANE programs have been shown to be beneficial, especially in large cities and metropolitan areas with multiple emergency departments of varying capability and staff training/experience.
- Give sedation and tetanus prophylaxis when indicated.
- Discuss possible pregnancy and pregnancy termination with the victim. If hospital policy precludes such as discussion, then information about this option should be offered to the victim via follow-up mechanisms.
- Discuss suspected HIV and hepatitis B exposure and testing with the victim in accordance with hospital, regional, and state policies/protocols. The initial HIV test should be completed within 7 days of the suspected exposure.

## MEDICATION

### *First Line*

- Controversy exists regarding empiric antibiotic prophylaxis for victims of sexual assault. However, the Centers for Disease Control and Prevention (CDC) recommends empiric antibiotic prophylaxis of potential sexually transmitted infections (specifically, gonorrhea, chlamydia, trichomoniasis, and potentially syphilis), as many patients will not return for a follow-up visit and many patients prefer immediate treatment (5)[C].
- Cultures are *not* required before initiating treatment but can be considered as part of routine evidence collection.
- Gonorrhea: ceftriaxone 250 mg IM once. Note: Be aware that drug resistance is on the rise in several major cities. Quinolones are no longer recommended for treatment of gonorrhea.
- Chlamydia: azithromycin 1 g PO single dose, or doxycycline 100 mg PO BID for 7 days, *or* erythromycin base 500 mg PO QID for 7 days, *or* erythromycin ethylsuccinate 800 mg PO QID for 7 days
- Syphilis: benzathine penicillin G 2 to 4 million units IM once, or doxycycline 100 mg PO BID for 14 days.

P.895

Some suggest ceftriaxone 1 g/day, either IM/IV, for 8 to 10 days, but treatment failures have been reported in several geographic areas.

- Trichomoniasis and bacterial vaginosis, if present (if cultures/wet mount were collected): metronidazole 2 g PO once, *or* metronidazole 500 mg PO BID for 7 days (consider single dose

to maximize compliance), *or* metronidazole gel 0.75% 1 full applicator (5 g) intravaginally every day for 5 days; *or* clindamycin cream 2% 1 full applicator (5 g) intravaginally at bedtime for 7 days (considered less efficacious than PO metronidazole)

- If pregnancy prophylaxis is indicated, use levonorgestrel 1.5 mg once (Plan B, progestin-only), efficacious for up to 5 days after the incident.
  - Levonorgestrel alone has proved more effective than the Yuzpe regimen, a method of emergency contraception.
  - *Alternatively*, ethinyl estradiol/levonorgestrel (Yuzpe) 100 &mgr;g/0.5 mg once and repeated in 12 hours can be used.
  - *Alternatively*, ulipristal acetate (Ella) 30 &mgr;g once can be used.
  - *Alternatively*, a copper intrauterine device can be inserted up to 5 days after the earliest predicted date of ovulation in that cycle (6)[C].
- HIV: Currently, there is a low likelihood of HIV transmittance, but the CDC still recommends postexposure prophylaxis (PEP) for victims of sexual assault. Regimen is PEP for 3 to 7 days, with short-term follow-up for further counseling, with a specialist familiar with PEP regimens.
  - Most effective if started within 4 hours and could reduce transmission by as much as 80%; unlikely to be beneficial if started after 72 hours.
- Hepatitis B: if prevalent in area or assailant known to be high risk: hepatitis B immunoglobulin 0.06 mL/kg IM, single dose, and initiate 3-dose hepatitis B virus immunization series. No treatment if the victim has had a complete hepatitis B vaccine series, with documented levels of immunity (7)[C].

## *Second Line*

### *Pregnancy Considerations*

Conduct baseline pregnancy test; discuss pregnancy prevention and termination with patient.

### *Pediatric Considerations*

Assure the child that she or he is a good person and was not the cause of the incident.

## **INPATIENT CONSIDERATIONS**

### *Admission Criteria/Initial Stabilization*

- Contact appropriate social services agency.
- Most adult victims can be treated as outpatients, unless associated trauma (physical/mental)

requires admission.

- Most pediatric sexual assault/abuse victims will require admission/outside placement until appropriate social agency can evaluate home environment (8)[C].

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Patient should be seen in 7 to 10 days for follow-up care, including pregnancy testing and counseling.
- Close exam for vaginitis and treatment if necessary
- Follow-up test for gonorrhea should occur in 1 to 2 weeks.
- Follow-up testing for syphilis, HIV, and hepatitis B should occur at 6 weeks, 3 months, and 6 months.
- Provide telephone numbers of counseling agency(ies) that can provide counseling/legal services to the patient.
- Strongly consider SANE, if available (9)[C].

### *PATIENT EDUCATION*

- Local rape crisis support organizations
- National Sexual Violence Resource Center, 123 Enola Drive, Enola, PA 17025; (877) 739-3895; [www.nsvrc.org](http://www.nsvrc.org)
- National Domestic Violence Hotline at (800) 799-SAFE(7233) or TTY (800) 787-3224 or [www.thehotline.org](http://www.thehotline.org)

### *PROGNOSIS*

- Acute phase (usually 1 to 3 weeks following rape): shaking, pain, wound healing, mood swings, appetite loss, crying. Also feelings of grief, shame, anger, fear, revenge, or guilt
- Late/chronic phase (also called Reorganization): Female victim may develop fear of intercourse, fear of men, anxiety or increase discomfort during Pap smears, nightmares, sleep disorders, daytime flashbacks, fear of being alone, loss of self-esteem, anxiety, depression, posttraumatic stress syndrome, and somatic complaints (e.g., nonspecific abdominal pain).
- Recovery may be prolonged. Patients who are able to talk about their feelings seem to have a

faster recovery. It is unclear if pharmacologic or psychotherapy results in better outcomes.

## COMPLICATIONS

Sequelae include the following:

- Trauma (physical and or mental)
- STIs, including HIV
- Unwanted pregnancy (with the possibility of abortion)
  - The rape-related pregnancy rate in the United States is 5% per rape among victims of reproductive age, resulting in >32,000 unwanted pregnancies each year.
  - Adolescents are at highest risk of pregnancy.
- Medical: chronic pain, fibromyalgia, headaches, irritable bowel syndrome, sexual dysfunction
- Psychological: anxiety, depression, posttraumatic stress disorder, eating disorder, substance abuse

## Codes

&NA;

### ICD10

- T74.21XA Adult sexual abuse, confirmed, initial encounter
- T74.22XA Child sexual abuse, confirmed, initial encounter
- Z04.41 Encounter for exam and obs following alleged adult rape

# Clinical Pearls

## &NA;

- *Rape* is a legal term, and the examining physician is encouraged to use terminology such as *alleged rape* or *alleged sexual conduct*.
- Marital rape is a federal offense in all 50 states and the District of Columbia; in some states, also applies to unmarried cohabiting couples.
- Because "consent defense" is common, documentation of evidence supporting the use of force or the administration of drugs/alcohol is imperative.
- Use of a protocol is encouraged to assure every victim a uniform, comprehensive evaluation, regardless of the expertise of the examiner. The protocol must ensure that all evidence is properly collected and labeled, chain of custody is maintained, and the evidence is sent to the most appropriate forensic laboratory.
- All medical records must be well documented and legible.
- All medical personnel must be willing and able to testify on behalf of the patient.

Opinions, interpretations, conclusions, and recommendations herein are those of the author and are not necessarily endorsed by the U.S. Army.*

# Raynaud Phenomenon

Herbert L. Muncie Jr., MD

Kelsey E. Phelps, MD

## BASICS

### DESCRIPTION

- Idiopathic intermittent episodes of vasoconstriction of digital arteries, precapillary arterioles, and cutaneous arteriovenous shunts in response to cold, emotional stress, or blunt trauma
  - A triphasic color change of the fingers (occasionally the toes, rarely nipples) is the principal physical manifestation.
    - The initial color is *white* from extreme pallor, then *blue* from cyanosis, and finally with warming and vasodilatation the skin appears *red*.
    - Thumbs are rarely involved.
  - Swelling, throbbing, and paresthesias are associated symptoms.
  - Primary
    - 80% of patients have primary disease.
    - Episodes are bilateral and nonprogressive.
    - Diagnosis confirmed if after 2 years of symptoms, no underlying connective tissue disease develops.
  - Secondary
    - Progressive and asymmetric
    - Vascular spasm is more frequent and more severe over time. Ulceration is rare; gangrene does not develop; 13% progress to digital fat pad atrophy and ischemic changes of the fingertips.
    - Typically associated with an underlying connective tissue disorder
- System(s) affected: hematologic, lymphatic, immunologic, musculoskeletal, dermatologic, exocrine

## *Pregnancy Considerations*

- Raynaud phenomenon can appear as breast pain in lactating women (1).
- Positive breast milk bacterial culture distinguishes mastitis from Raynaud phenomenon.

## *Geriatric Considerations*

Initial appearance of Raynaud phenomenon after age 40 years often indicates underlying connective tissue disease.

## *Pediatric Considerations*

Associated with systemic lupus erythematosus (SLE) and scleroderma

## **EPIDEMIOLOGY**

### *Incidence*

- Primary
  - Predominant age: 14 years; ÷1/4 begin >40 years
  - Predominant sex: female > male (4:1)
- Secondary
  - Predominant age: >40 years
  - Predominant sex: no gender predilection

### *Prevalence*

- Primary: 3-12.5% of men; 6-20% of women (based on clinical history)
- Secondary: ÷1% of population

## **ETIOLOGY AND PATHOPHYSIOLOGY**

Unknown. Dysregulation of vascular control mechanisms leads to imbalance between vasodilation and vasoconstriction. There is a reduced endothelin-dependent vasodilation activity and an increased vasoconstriction in peripheral vessels by overproduction of endothelin-1. 5-HT<sub>2</sub> serotonin receptors may be involved in secondary Raynaud phenomenon. Platelet and blood viscosity abnormalities in secondary contribute to ischemic pathology.

### *Genetics*

Some studies suggest dominant inheritance pattern. ÷1/4 of primary patients have a first-degree

relative with Raynaud phenomenon.

## **RISK FACTORS**

- Existing autoimmune or connective tissue disorder
- End-stage renal disease with hemodialysis may increase risk if a steal phenomenon associated with the arterial-venous shunt develops.
- Primary and secondary disease associated with elevated homocysteine levels.
- Smoking is not associated with increased risk of Raynaud phenomenon but may worsen symptoms.

## **GENERAL PREVENTION**

- Avoid cold exposure.
- Tobacco cessation
- No relationship has been established between Raynaud phenomenon and vibratory tool use.

## **COMMONLY ASSOCIATED CONDITIONS**

Secondary Raynaud

- Scleroderma; SLE; polymyositis
- Sjögren syndrome; occlusive vascular disease
- Cryoglobulinemia

## **DIAGNOSIS**

### **HISTORY**

- Primary
  - Symmetric attacks involving fingers
  - Family history of connective tissue disorder
  - Absence of tissue necrosis, ulceration, or gangrene
  - If after 2 years of symptoms, no abnormal clinical or laboratory signs have developed, secondary disease is highly unlikely.
- Secondary
  - Onset typically after 40 years of age
  - Asymmetric episodes more intense and painful

- Arthritis, myalgias, fever, dry eyes and/or mouth, rash, or cardiopulmonary symptoms
- History of medication and/or recreational drug use
- Exposure to toxic agents
- Repetitive trauma

## *PHYSICAL EXAM*

Pallor (whiteness) of fingertips with cold exposure, then cyanosis (blue), then redness and pain with warming

- Ischemic attacks evidenced by demarcated or cyanotic skin limited to digits; usually starts on one digit and spreads symmetrically to remaining fingers of both hands. The thumb is typically spared.
- May rarely involve other peripheral tissues (e.g., tongue) (2).
- Beau lines: transverse linear depressions in nail plate on most or all fingernails that occurs after exposure to cold or any insult that disrupts normal nail growth.
- Livedo reticularis: mottling of the skin of the arms and legs; benign and reverses with warming
- Primary
  - Normal physical exam
  - Nail bed capillaries have normal appearance: Place 1 drop of grade B immersion oil on skin at base of fingernail and view capillaries with hand-held ophthalmoscope at 10 to 40 diopters.
- Secondary
  - Skin changes, arthritis, and abnormal lung findings suggest connective tissue disease,
  - Ischemic skin lesions: ulceration of finger pads (autoamputation in severe, prolonged cases)
  - Nail bed capillary distortion including giant loops, avascular areas, and increased tortuosity
  - Abnormal Allen test: conducted by having the patient open and close his or her hand several times and then squeezing his or her hand tightly into a fist. The examiner sequentially occludes the ulnar and radial arteries while the patient opens his or her hand to reveal the return of color as a measure of circulation.

## *DIFFERENTIAL DIAGNOSIS*

- Thromboangiitis obliterans (Buerger disease): primarily affects men; smoking-related

- Rheumatoid arthritis (RA)
- Progressive systemic sclerosis (scleroderma): Raynaud phenomenon precedes other symptoms.
- SLE
- Carpal tunnel syndrome; thoracic outlet syndrome
- Hypothyroidism
- CREST syndrome (calcinosis cutis, Raynaud phenomenon, esophageal dysmotility, sclerodactyly, and telangiectasias)
- Cryoglobulinemia; Waldenström macroglobulinemia
- Acrocyanosis
- Polycythemia
- Occupational (e.g., especially from vibrating tools, masonry work, exposure to polyvinyl chloride)
- Drug-induced (e.g., clonidine, ergotamine, methysergide, amphetamines, bromocriptine, bleomycin, vinblastine, cisplatin, cyclosporine)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Provocative test (e.g., ice water immersion) unnecessary

- Primary
  - Antinuclear antibody: negative
  - ESR: normal
- Secondary
  - Tests for secondary causes (e.g., CBC, ESR)
  - Positive autoantibody has low positive predictive value for connective tissue disease (30%).
  - Antibodies to specific autoantigens (e.g., scleroderma with anticentromere or antitopoisomerase antibodies)
  - Videocapillaroscopy is gold standard (200 times magnification).

## **Follow-Up Tests & Special Considerations**

Periodic assessments for a connective tissue disorder

## *Diagnostic Procedures/Other*

Diagnosis is determined by history and physical exam.

## **TREATMENT**

Assess using a Raynaud Condition Score.

## **GENERAL MEASURES**

- Dress warmly, wear gloves, and avoid cold temperatures.
- During attacks, rotate the arms in a windmill pattern or placing the hands under warm water or in a warm body fold to alleviate symptoms.
- Tobacco cessation
- Avoid  $\beta$ -blockers, amphetamines, ergot alkaloids, and sumatriptan.
- Temperature-related biofeedback may help patients increase hand temperature. 1-year follow-up is no better than control.
- Finger guards to protect ulcerated fingertips

## **MEDICATION**

### *First Line*

- Calcium channel blockers (CCBs). Nifedipine is the best studied and most frequently used.
- Nifedipine: 30 to 180 mg/day (sustained-release form); seasonal (winter) use is effective with up to 75% of patients experiencing improvement.
- Is compatible with breastfeeding
- Contraindications: allergy to drug, pregnancy, CHF
- Precautions: may cause headache, dizziness, lightheadedness, edema, or hypotension
- Significant possible interactions
  - Increases serum level of digoxin

### *Second Line*

- Amlodipine (5 to 10 mg/day) and nifedipine are effective and may have fewer adverse effects.

No data exist to support switching CCB if initial drug is ineffective.

- Small studies support benefit from losartan and fluoxetine.
- Phosphodiesterase type-5 inhibitors (sildenafil, vardenafil) may reduce symptoms without increasing blood flow.
- Parenteral iloprost, a prostacyclin, in low doses (0.5 ng/kg/min over 6 hours), has improved ulcerations with severe Raynaud phenomenon when CCBs failed. Oral prostacyclin has not proven useful.
- Nitroglycerin patches may be helpful, but use is limited by the incidence of severe headache. Nitroglycerin gel has shown promise as a topical therapy.
- Prazosin (1 to 2 mg TID) is the only well-studied  $\alpha_1$ -adrenergic receptor blocker with modest effect, but adverse effects may outweigh any benefit.
- ACE inhibitors are no longer recommended.

## ISSUES FOR REFERRAL

If an underlying disease is suspected, consider rheumatology consultation for evaluation and treatment.

## ADDITIONAL THERAPIES

- Botulinum toxin has shown some effect in reducing vasospastic episodes, frequency of attacks, rest pain, and helping to promote digital ulcer healing (3)[C].
- Aspirin
- Digital or wrist block with lidocaine or bupivacaine (without epinephrine) for pain control
- Short-term anticoagulation with heparin if persistent critical ischemia, evidence of large-artery occlusive disease, or both

## SURGERY/OTHER PROCEDURES

Surgical intervention is rarely indicated or used for Raynaud phenomenon. Effect of cervical sympathectomy is transient; symptoms return in 1 to 2 years. Digital fat grafting is a novel modality that has shown improved symptomatology and evidence of measurably increased perfusion in several cases; further study is needed (4)[C].

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- *Ginkgo biloba* may reduce the frequency of attacks.
- Well-designed studies have not been done yet (5)[B].

- Fish oil supplements may increase digital systolic pressure and time to onset of symptoms after exposure to cold; not proven in controlled trials
- Vitamin D supplementation led to improvement in self-reported symptoms in vitamin D-deficient patients with Raynaud phenomenon (6)[B].
- Evening primrose oil reduced severity of attacks in one study.
- Oral arginine is no better than placebo.
- Biofeedback is not helpful.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Avoid exposure to cold; reassess for secondary causes.

### *Patient Monitoring*

Manage fingertip ulcers and rapidly treat infection.

### *DIET*

No special diet.

### *PATIENT EDUCATION*

- Tobacco cessation.
- Avoid triggers (e.g., trauma, vibration, cold).
- Dress warmly; wear gloves.
- Warm hands when experiencing vasospasm.

### *PROGNOSIS*

- Attacks may last from several minutes to a few hours.
- 2/3 of attacks resolve spontaneously.
- ÷13% of Raynaud patients develop a secondary disorder, typically connective tissue diseases.

### **COMPLICATIONS**

- Primary: very rare
- Secondary: gangrene, autoamputation of fingertips

Algorithm: Raynaud Phenomenon

## Codes

&NA;

### ICD10

- I73.00 Raynaud's syndrome without gangrene
- I73.01 Raynaud's syndrome with gangrene

## Clinical Pearls

&NA;

- The diagnosis of Raynaud phenomenon is based on clinical symptoms.
- Provocative testing is not recommended.
- Initial presentation of Raynaud phenomenon after age 40 years suggests underlying (secondary) disease.
- Raynaud phenomenon is a cause of breast pain in lactating women.
- Primary Raynaud phenomenon is symmetric; secondary Raynaud phenomenon is asymmetric.
- Primary Raynaud phenomenon is treated with handwarming and avoiding cold exposure.
- Digital ulcers are not normal and always merit a workup for secondary disease.

# Reactive Arthritis (Reiter Syndrome)

Douglas W. MacPherson, MD, MSc-CTM, FRCPC

## BASICS

Reiter syndrome is a seronegative, multisystem, inflammatory disorder classically involving joints, the eye, and the lower genitourinary (GU) tract. Axial joint (e.g., spine, sacroiliac joints) and dermatologic manifestations are common (1)[C].

## DESCRIPTION

The classic triad include arthritis, conjunctivitis/iritis, and either urethritis or cervicitis (Can't see; can't pee; can't bend my knee).

- The epidemiology is similar to other reactive arthritides, characterized by sterile joint inflammation associated with infections originating at nonarticular sites. A fourth feature (dermatologic involvement) may include buccal ulceration, balanitis, or a psoriaform skin eruption. (Having only two features does not rule out the diagnosis.)
- Two forms of Reiter syndrome:
  - Sexually transmitted: Symptoms emerge 7 to 14 days after exposure to *Chlamydia trachomatis* and other sexually acquired pathogens.
  - Postenteric infection (including traveler's diarrhea)
- In individuals with new or frequent sexual partners, the triggering infection is likely sexually transmitted (rather than enteric).
- In individuals with a history of recent enteric illness, the triggering event is more likely to be a bacterial enteric infection than sexually transmitted.
- System(s) affected: musculoskeletal, renal/urologic, dermatologic/exocrine
- Synonym(s): idiopathic blennorrhoeal arthritis; arthritis urethritica; urethro-oculosynovial syndrome; Fiessinger-Leroy-Reiter disease; reactive arthritis

## Pediatric Considerations

Juvenile rheumatoid arthritis has many of the same clinical features as Reiter syndrome.

## Pregnancy Considerations

No special considerations; usual drug precautions

## **EPIDEMIOLOGY**

### ***Incidence***

- Predominant age: 20 to 40 years
- Predominant sex: male > female
- 0.24-1.5% incidence after epidemics of bacterial dysentery
- Complicates 1-2% of nongonococcal urethritis cases

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- The pathophysiology of all the seronegative reactive arthritis syndromes and the immunologic role of infectious diseases as precipitants for clinical illness are incompletely understood.
- Avoiding precipitant infections and early management of multiorgan inflammation is important. Antibiotic treatment following onset of syndrome does not appear to benefit inflammatory joint, eye, or urinary tract symptoms.
- *C. trachomatis* is the most common sexually transmitted infection associated with Reiter syndrome.
- Dysentery-associated Reiter syndrome follows infection with *Shigella*, *Salmonella*, *Yersinia*, and *Campylobacter* spp. Enteric-associated Reiter syndrome is more common in women, children, and the elderly than the postvenereal form.

### ***Genetics***

HLA-B27 tissue antigen present in 60-80% of patients, suggesting a genetic predisposition.

## **RISK FACTORS**

- New or high-risk sexual contacts 7 to 14 days before the onset of clinical presentation; the primary infection may be subclinical and undiagnosed.
- Food poisoning or bacterial dysentery

## **GENERAL PREVENTION**

- The immune-response characteristics of this syndrome make specific avoidance of infectious precipitants the most important general precaution (and potentially the most difficult to achieve).
- Safe sexual practices; proper food and water hygiene

## COMMONLY ASSOCIATED CONDITIONS

- Enteric disease
  - Shigellosis; Salmonellosis; Campylobacteriosis
  - Enteric infection with *Yersinia* spp.
- Urogenital infection
  - *Chlamydia* urethritis/cervicitis (2)[C]
  - *Mycoplasma* or *Ureaplasma* spp.
- HIV/AIDS

## DIAGNOSIS

- Based on clinical presentation with joint, eye, and GU inflammation (Òclassic triadÓ) and negative serologic testing for rheumatoid factor
- Classic symptoms not always present at the same time
- HLA-B27 testing is not required for diagnosis.

## HISTORY

The presence of the clinical syndrome plus

- Diarrhea, dysentery, urethritis, or genital discharge and appropriate exposure history
- Exposure risks, including travel or migration history and potential infectious exposure
- Arthritis associated with urethritis for >1 month (84% sensitive; 98% specific for diagnosis)
- Urethritis occurs 1 to 15 days after sexual exposure.
- Reiter syndrome onset within 10 to 30 days of either enteric infection or STI
- Mean duration of symptoms is 19 weeks.

## PHYSICAL EXAM

- Musculoskeletal
  - Asymmetric arthritis (especially knees, ankles, and metatarsophalangeal joints)

Enthesopathy (inflammation at tendinous insertion into bone, such as plantar fasciitis, digital periostitis, and Achilles tendinitis)

- Spondyloarthropathy (spine and sacroiliac joint involvement)
- Urogenital tract
  - Urethritis; prostatitis; cystitis (rare)
  - Balanitis
  - Cervicitis: usually asymptomatic
- Eye
  - Conjunctivitis of one or both eyes
  - Occasionally, scleritis, keratitis, and corneal ulceration
  - Rarely, uveitis and iritis
- Skin
  - Mucocutaneous lesions (small, painless superficial ulcers on oral mucosa, tongue, or glans penis)
  - Keratoderma blennorrhagica (hyperkeratotic skin lesions of palms and soles and around nails—can be mistaken for psoriasis)
- Cardiovascular: occasionally, pericarditis, murmur, conduction defects, and aortic incompetence
- Nervous system: rarely, peripheral neuropathy, cranial neuropathy, meningoencephalitis, and neuropsychiatric changes
- Constitutional
  - Fever, malaise, anorexia, and weight loss
  - Patient can appear seriously ill (e.g., fever, rigors, tachycardia, and exquisitely tender joints).

## *DIFFERENTIAL DIAGNOSIS*

- Rheumatoid arthritis (RA)
- Ankylosing spondylitis
- Arthritis associated with inflammatory bowel disease
- Psoriatic arthritis

- Juvenile RA
- Bacterial arthritis, including gonococcal

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Blood
  - Negative rheumatoid factor
  - Leukocyte count: 10,000 to 20,000 cells/mm<sup>3</sup>
  - Neutrophil predominance
  - Elevated ESR and/or CRP
  - Moderate normochromic anemia
  - Hypergammaglobulinemia
- Synovial fluid
  - Leukocyte count: 1,000 to 8,000 cells/mm<sup>3</sup>
  - Bacterial culture negative
- Supportive tests
  - Cultures, antigens, or PCR positive for *Chlamydia trachomatis* or stool test positive for *Salmonella*, *Shigella*, *Yersinia*, or *Campylobacter* species
  - HIV serology positive (acute retroviral syndrome)
  - HLA-B27-positive (*not required for diagnosis*)
  - Drugs that may alter lab results: Antibiotics may affect isolation of the bacterial pathogens.
- X-ray
  - Periosteal proliferation, thickening
  - Articular bony spurs; erosions at articular margins
  - Residual joint destruction
  - Syndesmophytes (spine); sacroiliitis

### ***Diagnostic Procedures/Other***

HLA-B27 histocompatibility antigen: positive result in 60-80% of cases in non-HIV-related Reiter syndrome; HLA testing is not required or recommended for diagnosis. Rheumatoid factor is

negative.

- Screen for STI if clinically indicated.
- Screening for enteric infections is rarely useful and generally not indicated.

### *Test Interpretation*

- Seronegative spondyloarthritis (similar to ankylosing spondylitis, enteric arthritis, and psoriatic arthritis)
- Villous formation within joints; hyperemia, and inflammation
- Prostatitis and seminal vesiculitis
- Skin biopsy similar to psoriasis

---

P.899

## **TREATMENT**

### *GENERAL MEASURES*

Treatment is determined by symptoms.

- Conjunctivitis does not require specific treatment.
- Iritis requires treatment.
- Mucocutaneous lesions do not require treatment.
- Physical therapy (PT) aids recovery.
- Arthritis may become prominent and disabling during the acute phase.

### *MEDICATION*

#### *First Line*

- Symptomatic management: NSAIDs, including indomethacin, naproxen, and others; intra-articular or systemic corticosteroids for refractory arthritis and enteritis
  - Contraindications
    - GI bleeding
    - Peptic ulcer, gastritis, or ulcerative colitis
    - Renal insufficiency

- Specific treatment of isolated microorganism (3)[A]:
  - *C. trachomatis*: doxycycline 100 mg PO BID for 7 to 14 days (*Note*: All STIs should be treated whether associated with Reiter syndrome or not.)
  - *Salmonella*, *Shigella*, *Yersinia*, and *Campylobacter* infections: ciprofloxacin 500 mg PO BID for 5 to 10 days (*Note*: Emerging antimicrobial resistance may limit the effectiveness of ciprofloxacin. Antibiotic treatment does not reduce GI symptoms or duration of infection or prevent carrier state.)
  - Trials of antibiotic treatment for reactive arthritis have produced mixed results, rendering the efficacy of antibiotics uncertain.
- GI upset: antacids
- Iritis: intraocular steroids
- Keratitis: topical steroids

## *Second Line*

- Aspirin or other NSAIDs
- Sulfasalazine is promising but not approved by the FDA for this indication.
- Methotrexate or azathioprine in severe cases (experimental, not approved or known to be effective); immunosuppressive therapy is relatively contraindicated in HIV-related Reiter syndrome.
- Consultation with specialist is recommended, particularly when considering immunomodulatory agents such as sulfasalazine, methotrexate, or azathioprine or for treatment with anti-TNF medications (etanercept and infliximab) which have shown benefit in isolated case reports.
- Role of antibiotics under investigation—currently unproven effectiveness in seronegative arthritides.
- No published evidence supports the beneficial effect of antibiotics on the long-term outcome in patients with Reiter syndrome.

## *ISSUES FOR REFERRAL*

Joint and eye complications; complex cases—consider reconsultation with rheumatology; ophthalmology

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Based on severity of disease and associated complications
- Inpatient care may be needed during acute phase.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Activity modification until joint inflammation subsides

### *Patient Monitoring*

Monitor clinical response to anti-inflammatory drugs. Observe for complications, particularly with sulfasalazine and immunosuppressive drugs.

### *PATIENT EDUCATION*

- Educate on risk factors for exposure and recurrence.
- Home physical therapy
- Arthritis Foundation, 1314 Spring Street NW, Atlanta, GA 30309, 404-872-7100
- National Institute of Arthritis and Musculoskeletal and Skin Diseases:  
<http://www.niams.nih.gov/>

### *PROGNOSIS*

Prognosis is poor in cases involving the heel, eye, or heart.

### **COMPLICATIONS**

- Chronic or recurrent disease in 5-50% of patients
- Ankylosing spondylitis develops in 30-50% of patients who test positive for HLA-B27 antigen.
- Urethral strictures
- Cataracts and blindness
- Aortic root necrosis

### &NA;

Ankylosing Spondylitis; Arthritis, Psoriatic; Behçet Syndrome

**&NA;**

## **ICD10**

- M02.30 Reiter's disease, unspecified site
- M02.39 Reiter's disease, multiple sites

## **Clinical Pearls**

**&NA;**

- Diagnosis of Reiter syndrome is based on the clinical presentation of the classic triad of joint, eye, and GU inflammation and negative serologic testing for rheumatoid factor (signs and symptoms may not all be present at the same time).
- Screen for STI (including HIV) if sexually acquired. Enteric studies are rarely clinically indicated.
- Refer patients with a chronic or recurrent course or those who have clinical complications.

# Refractive Errors

Robert M. Kershner, MD, MS, FACS

## BASICS

### DESCRIPTION

- Refraction is the bending of a wave of light as it passes through the optical system of the eye. The degree of bending is dependent on the index of refraction through the air, cornea, and lens and is described quantitatively by Snell law. A refractive error refers to the inability of the eye to produce a focused image on the fovea or central part of the retina.
- Emmetropia: When light rays are in perfect focus, the image being viewed is seen clearly.
- Ametropia: any refractive error of the eye that prevents normal focusing of the image
- Hyperopia: When the cornea of the eye is too flat or the eye is too short, light rays fall in focus behind the retina, and the individual is Òfarsighted.Ó
- Myopia: When the cornea is too steep or the length of the eyeball is too long, the focal point for light rays lies short of the retina, and the individual is Ònearsighted.Ó
- Presbyopia: The natural tendency of the crystalline lens to harden/become sclerotic with age, limiting the focusing of the eye on near objects (accommodation). By the age of 40 years, most people do not have enough room within the eye to allow normal excursion of the lens and accommodation; viewing of near objects is blurred, and reading glasses are required.
- Astigmatism: When the cornea is steeper in one meridian more than the other or the globe is not round (i.e., is oval or almond shaped), visual blurriness occurs due to the absence of a single point of focus.
- Anisometropia: an unequal refractive error between the two eyes
- System(s) affected: nervous

### *Geriatric Considerations*

Presbyopia occurs after the age of 40 years.

### *Pediatric Considerations*

Refractive errors can be detected early in life.

## EPIDEMIOLOGY

- Predominant age: Refractive errors may be present at birth and can increase in magnitude with age until the eye is fully developed. Often they are not detected until puberty.
- Predominant gender: male = female
- Individuals >40 years of age are more likely to experience presbyopia/the normal loss of accommodation that occurs with age, necessitating the use of reading glasses for close work.

## Prevalence

Of the general U.S. population, 70% have some form of ametropia.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Developmental (most common)
- Ocular trauma
- Iatrogenic (e.g., post refractive surgery or cataract removal)

## Genetics

Inherited

## GENERAL PREVENTION

No exercises; optical lenses can correct the refractive error.

## COMMONLY ASSOCIATED CONDITIONS

- Patients with diabetes mellitus have fluctuating myopia as a result of poorly controlled blood glucose and concomitant swelling of the crystalline lens.
- Those who have a pathologic steepening of the cornea due to structural weakness (keratoconus) may have increasing myopia and astigmatism throughout life.

## DIAGNOSIS

### HISTORY

- Difficulty seeing objects at a distance
- Difficulty focusing on near objects
- Difficulty reading
- Squinting

- Headaches (from squinting)
- In children:
  - Rubbing of the eyes
  - Sitting close to TV/computer screen
  - Problems in sports, particularly declining performance
  - Declining grades
  - Preference for front-row seating
  - Covering of an eye while reading

## *PHYSICAL EXAM*

Snellen eye chart (developed by Dr. Hermann Snellen in 1862)

- Test each eye separately.
- The smallest row of letters that the patient can read determines visual acuity in the uncovered eye.
- The standard convention is visual acuity measured at 20 feet with a Snellen chart. A person with "normal" acuity will see letters clearly at 20 feet as recorded 20/20 (6/6 in meters). A person with 20/200 vision would be considered legally blind and able only to see a letter at 20 feet that a person with normal vision could see clearly at 200 feet.

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Pinhole vision test: To distinguish a refractive error from an organic cause of visual blurring, have the patient look through a pinhole in a card without a corrective lens.
- Patients with a pure refractive error have improved vision because the pinhole blocks nonparallel and unfocused rays of light.
- There are no lab tests for measuring visual acuity.
- A number of digital imaging systems exist for measuring refractive error.
  - Ultrasound or Laser Interferometry can determine the length of the eye (A-Scan or Laser Biometry).
  - Autorefractors can measure myopia, hyperopia, and astigmatism using a projected light into the eye and measuring the quality of its image upon its return.
  - Corneal topography or Orbscan quantitatively and qualitatively measures the amount of curvature on the surface of the cornea that affects the bending and focusing of light on the retina.

- Wavefront corneal analysis measures the reflected rays of light as they pass into and out of the entire optical system (cornea, lens, and retina).
- Most corneal and refractive imaging techniques are reserved for individuals who are contemplating refractive surgical correction (intraocular lenses or excimer laser surgery LASIK).

## Follow-Up Tests & Special Considerations

Corneal and refractive imaging are used to monitor changing refractive errors postsurgically and to follow pathologic changes such as in keratoconus.

### *Diagnostic Procedures/Other*

- Methods
  - Objective streak retinoscopy may be used to measure the degree of refractive error in spherocylinder correction for the proper spectacle/contact lens.
  - Antimuscarinic agents, such as cyclopentolate (Cyclogyl) or tropicamide (Mydracyl), applied topically paralyze the ciliary body, preventing accommodation. Cycloplegic refraction can then be performed.
  - *&agr;*-Adrenergic agents, such as phenylephrine (Neo-Synephrine), can be used concomitantly to stimulate and dilate the pupillary dilator muscle, making measurements easier. They have no effect on cycloplegia.
- Age-related testing
  - Newborns should be examined for general eye health; ophthalmologic evaluation is indicated for any problems discovered.
  - Vision screening should occur at each well-child visit.
  - Visual acuity testing and motility testing should be performed at  $\pm$  3 to 5 years of age or at any time that a malposition of the eyes, squinting, or difficulty following objects is observed.
  - Visual acuity must be performed by age 5 years or prior to the child entering school to screen for and pick up refractive errors early before they lead to amblyopia.
  - Visual acuity should be retested prior to obtaining a driver's license, at age 40 years, and every 2 to 4 years until age 65 years, after which age evaluations are recommended every 1 to 2 years.

## DIFFERENTIAL DIAGNOSIS

- Corneal disease

- Cataract
- Retinal abnormalities
- Diseases of the optic nerve
- Neuromuscular disorders
- Neurologic impairment

## TREATMENT

### GENERAL MEASURES

- Spectacle lenses (glasses)
- Soft/hard contact lenses
- Surgery

### MEDICATION

Precaution: Antimuscarinic agents may induce acute glaucoma via acute-angle closure in susceptible individuals. The elderly and those with high hyperopia or a history of angle closure should not be tested with these agents.

#### *First Line*

No medical treatment for refractive error exists.

#### *Second Line*

Cycloplegia is sometimes used to "fog/blur" the better seeing eye in cases of amblyopia.

### ISSUES FOR REFERRAL

Any individual who fails a basic screening visual acuity test should be promptly referred to an eye care professional for evaluation. Children do not outgrow refractive errors. Left untreated, refractive errors can lead to permanent visual loss.

---

P.901

### ADDITIONAL THERAPIES

Eye exercises and visual training may improve hand-to-eye coordination and visual awareness but do not treat refractive error.

## *SURGERY/OTHER PROCEDURES*

- Astigmatic keratotomy with a surgical diamond blade has been performed either as an isolated procedure or as a part of the cataract surgical procedure to effectively flatten the steep corneal meridian (1,2)[C].
- Manual astigmatic keratotomy is being superseded by the femtosecond laser whereby the surgeon applies the laser to perform the limbal corneal relaxing incisions (LRIs) instead of the surgical diamond blade (3)[C].
- Laser-assisted in-situ keratomileusis (LASIK) was approved by the FDA in 1997. A superficial corneal flap is created with a mechanical keratome/femtosecond laser, under which the excimer laser removes a small amount of tissue corresponding to the correction of refractive error, thus reshaping the cornea. LASIK can be used for all refractive errors but not in all patients. Healing is rapid because reepithelialization is not required. Surgery is reserved for those with a stable refractive error and a cornea that is thick enough to allow safe removal of tissue. The procedure is permanent.
- Implantable contact lens (ICL): A thin plastic lens is permanently implanted either in the anterior chamber and anchored to the iris (FDA approved in 2005, VERISYSE) or in the posterior chamber (Visian ICL, FDA approved in 2006) between the iris and the human crystalline lens. All refractive errors can be corrected. Risks include damage to the natural lens during surgery, cataract formation, and intraocular inflammation/infection.
- Excimer laser photorefractive keratectomy: The laser photoablates corneal tissue from the central visual axis, flattening it. Following the procedure, the cornea must reepithelialize. Healing takes several months, during which there is a mild haze and blurring of vision; FDA approved in October 1995.
- Other modifications:
  - LASIK (laser in-situ keratomileusis), which involves removing of the superficial epithelium before laser application (Epi-LASIK).
  - IntraLASIK is a femtosecond laser that is used to create the flap as an alternative to a mechanical keratome.
  - Custom ablation: uses the information from a wavefront map of the cornea and eye to tailor the ablation to remove higher orders of refractive errors
- Older methods now superseded by LASIK:
  - Radial keratotomy: With topical anesthesia, a surgical keratome is used to incise multiple (4 to 8) radial incisions into the peripheral cornea to a depth of <sup>3</sup>85%. The incisions cause gaping and thus flatten the central, optical zone of the cornea. Radial keratotomy is safe and effective, corrects nearsightedness and astigmatism, but has been replaced by excimer

laser surgery for its improved accuracy and stability of correction.

- Photorefractive keratectomy: Surface corneal tissue is removed with the excimer laser to reshape the cornea, correcting nearsightedness, farsightedness, or astigmatism. Risks and disadvantages include pain, keratitis, and potential scarring. Healing requires 3 months with topical antibiotics and steroids, with associated risks of glaucoma, cataract, chronic inflammation, and scarring.
- Several scleral expansion procedures have been under investigation to attempt to increase the space within the ciliary body by surgical means to restore lens movement and accommodation. The results have been unsatisfactory.
- Bifocal intraocular lenses (several types have been approved by the FDA: AcrySof IQ ReSTOR, ReZOOM-AMO, TECNIS-AMO) are implanted in the posterior chamber. They increase the depth of field to allow viewing objects both at near and at distance. Side effects include decreased contrast, glare, ghosting of images, and problems with night vision.
- Accommodative intraocular lenses (Crystalens): first FDA-approved intraocular lens; several others under clinical investigation. The accommodative intraocular lens moves in response to ciliary body movement to allow focusing at different focal lengths. Side effects are minimal. Present lenses have limited range of focus.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Exams recommended when starting school, entering college, with any change in vision quality, and at the age of onset of presbyopia (the need for reading glasses)
- Individuals with any of the known risks of eye disease or conditions that could affect the eyes (e.g., diabetes, thyroid disease, hypertension, macular degeneration) need annual ocular examinations.
- Family history of eye diseases/refractive errors necessitates annual reexam.

#### *DIET*

Although refractive error is unaffected by diet, diet has been shown to be important for retinal health. Diets high in fats, cholesterol, along with cigarette smoking or diabetes can lead to an increased risk of age-related macular degeneration (AMD), a potentially blinding disease of the retina. Diets high in vegetables, low in meats, and high in antioxidants (e.g., lutein, & bgr;- carotene, vitamins A, C, and E, zinc, and omega-3 fatty acids) have been shown to be protective

for retinal degeneration. The age-related eye disease study (AREDS) formulation, which has been proven effective in numerous clinical trials, includes a specific daily amount of 500-mg vitamin C, 400 IU of vitamin E, 15 mg of  $\beta$ -carotene (often labeled as the equivalent of 25,000-IU vitamin A), 80 mg of zinc as zinc oxide, and 2 mg of copper as cupric oxide to prevent copper deficiency anemia and is taken with meals in two equally divided doses in the morning and evening. This therapy has been superseded by the AREDS2 formulation, which eliminated vitamin E due to its associated increased risk of lung cancer in smokers and replacing  $\beta$ -carotene with lutein and zeaxanthin.

## **PATIENT EDUCATION**

- All patients should have their eyes examined when starting school and periodically thereafter.
- The options of eyeglasses, contact lenses, and permanent surgical correction of refractive errors can be considered.
- Encourage aggressive control of diabetes mellitus and annual exams by an ophthalmologist. These individuals are at increased risk of blindness from their disease and should not undergo refractive corrective surgery.

## **PROGNOSIS**

- Good, if discovered early and corrected appropriately.
- It is not unusual for refractive errors to be temporarily worsened during pregnancy because of hormonal changes in tear function and corneal swelling.
- It is common that refractive errors worsen as a child ages until complete adult growth has been achieved (this is around age 18 to 20 years for girls and 20 to 25 years for boys). This is a common source of concern for parents. Reassurance that refractive change is often seen with growth spurts, especially at puberty, is advised.
- Any refractive change that is increasing/worsening each year should prompt further investigation by an ophthalmologist.

## **COMPLICATIONS**

- Amblyopia or permanent loss of vision that is not correctable with glasses or contact lenses
- Poor school performance
- Inability to pass a drivers license examination

- National Eye Institute. *Facts About Refractive Errors*. Bethesda, MD: National Eye Institute; 2009. <http://www.nei.nih.gov/health/errors/errors/.asp>.

## Codes

&NA;

### ICD10

- H52.7 Unspecified disorder of refraction
- H52.00 Hypermetropia, unspecified eye
- H52.10 Myopia, unspecified eye

## Clinical Pearls

&NA;

- Vision screening should occur at each well-child visit.
- Visual acuity testing should be performed at  $\pm$  3.5 years of age or at any time that the physician or parent is concerned about the child's eye movements, ability to see, or track objects.
- Children *never* grow out of a refractive error. All suspected refractive errors should be referred to the appropriate eye care professional for evaluation to prevent permanent loss of vision from amblyopia.

# Renal Tubular Acidosis

Jason Kurland, MD

## BASICS

### DESCRIPTION

- Renal tubular acidosis (RTA) is composed of a group of disorders characterized by an inability of the kidney to resorb bicarbonate/secrete hydrogen ions, resulting in normal anion gap metabolic acidosis. Renal function (glomerular filtration rate [GFR]) must be normal or near normal.
- Several types have been identified:
  - Type I (distal) RTA: inability of the distal tubule to acidify the urine due to impaired hydrogen ion secretion, increased back leak of secreted hydrogen ions, or impaired sodium reabsorption (interfering with the generation of negative luminal charge required for hydrogen/potassium secretion). Urine pH >5.5.
  - Type II (proximal) RTA: defect of the proximal tubule in bicarbonate ( $\text{HCO}_3$ ) reabsorption. Proximal tubular  $\text{HCO}_3$  reabsorption is absent; plasma  $\text{HCO}_3$  concentration stabilizes at 12 to 18 mEq/L due to compensatory distal  $\text{HCO}_3$  reabsorption. Urine pH <5.5 unless plasma  $\text{HCO}_3$  brought above reabsorptive threshold.
  - Type III RTA: extremely rare autosomal recessive syndrome due to carbonic anhydrase II deficiency; causes mixed type I and type II RTA, osteopetrosis, cerebral calcification, mental retardation
  - Type IV RTA (hypoaldosteronism): due to aldosterone resistance/deficiency that results in hyperkalemia. Urine pH usually is <5.5.

### EPIDEMIOLOGY

#### Incidence

- Predominant age: all ages
- Predominant sex: male > female (with regard to type II RTA with isolated defect in bicarbonate reabsorption)

# ETIOLOGY AND PATHOPHYSIOLOGY

- Type I RTA
  - Genetic: autosomal dominant, autosomal recessive associated with sensorineural deafness
  - Sporadic
  - Other familial disorders: Ehlers-Danlos syndrome, glycogenosis type III, Fabry disease, Wilson disease
  - Autoimmune diseases: Sjögren syndrome, rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), thyroiditis (1)
  - Hematologic diseases: sickle cell disease (hyperkalemic), hereditary elliptocytosis
  - Medications: amphotericin B, lithium, ifosfamide, foscarnet, amiloride, triamterene, trimethoprim, pentamidine
  - Toxins: toluene, glue
  - Hypercalciuria, diseases causing nephrocalcinosis
  - Vitamin D intoxication
  - Medullary cystic disease
  - Obstructive uropathy (hyperkalemic)
  - Hypergammaglobulinemic syndrome
  - Chronic pyelonephritis
  - Chronic renal transplant rejection
  - Leprosy
  - Chronic active hepatitis, primary biliary cirrhosis
  - Malnutrition
- Type II RTA
  - Familial (cystinosis, tyrosinemia, hereditary fructose intolerance, galactosemia, glycogen storage disease type I, Wilson disease, Lowe syndrome, inherited carbonic anhydrase deficiency)
  - Sporadic
  - Multiple myeloma, other dysproteinemic states
  - Amyloidosis
  - Heavy metal poisoning (e.g., cadmium, lead, mercury, copper)

- Medications: acetazolamide, ifosfamide, tenofovir, sulfanilamide, outdated tetracycline, topiramate (2), aminoglycosides
- Interstitial renal disease
- Paroxysmal nocturnal hemoglobinuria
- Defects in calcium metabolism (hyperparathyroidism)
- Type IV RTA
  - Medications: NSAIDs, ACE inhibitors, ARBs, heparin/low-molecular-weight heparin, ketoconazole, calcineurin inhibitors (tacrolimus, cyclosporine) by decreasing expression of mineralocorticoid receptor [3])
  - Diabetic nephropathy
  - Tubulointerstitial nephropathies
  - Primary adrenal insufficiency
  - Markedly decreased distal Na<sup>+</sup> delivery
  - Pseudohypoaldosteronism (PHA) (end-organ resistance to aldosterone)
    - PHA type 1
    - PHA type 2 (Gordon syndrome)

## *Genetics*

- Type I RTA: Hereditary forms due to mutations affecting intercalated cells in collecting tubules (4). May occur in association with other genetic diseases (e.g., Ehlers-Danlos syndrome, hereditary elliptocytosis, or sickle cell nephropathy). The autosomal recessive form is associated with sensorineural deafness.
- Type II RTA: Autosomal dominant form is rare. Autosomal recessive form is associated with ophthalmologic abnormalities and mental retardation. Occurs in Fanconi syndrome, which is associated with several genetic diseases (e.g., cystinosis, Wilson disease, tyrosinemia, hereditary fructose intolerance, Lowe syndrome, galactosemia, glycogen storage disease, metachromatic leukodystrophy)
- Type IV RTA: Some cases are familial, such as PHA type I (autosomal dominant).

## **GENERAL PREVENTION**

Careful use/avoidance of causative agents

## COMMONLY ASSOCIATED CONDITIONS

- Type I RTA in children: hypercalciuria leading to rickets, nephrocalcinosis
- Type I RTA in adults: autoimmune diseases (Sjögren syndrome, RA, SLE), hypercalciuria
- Type II RTA: Fanconi syndrome (generalized proximal tubular dysfunction resulting in glycosuria, aminoaciduria, hyperuricosuria, phosphaturia, bicarbonaturia)
- Type II RTA in adults: multiple myeloma, carbonic anhydrase inhibitors (acetazolamide) (5)
- Type IV RTA: diabetic nephropathy

## DIAGNOSIS

### HISTORY

- Often asymptomatic (particularly type IV)
- In children: failure to thrive, rickets
- Anorexia, nausea/vomiting, constipation
- Weakness or polyuria (due to hypokalemia)
- Polydipsia
- Osteomalacia in adults

## DIFFERENTIAL DIAGNOSIS

- Plasma anion gap should be normal. If not, evaluate for causes of anion-gap metabolic acidosis. (MUDPILES: **m**ethanol, **u**remia, **d**iabetic ketoacidosis, **p**ropylene glycol/paraldehyde, **i**ron/isoniazid ingestion, **l**actic acidosis, **e**thylene glycol, **s**alicylates)
- Extrarenal HCO<sub>3</sub> losses
  - Diarrhea
  - Small bowel, pancreatic, or biliary fistulas
  - Urinary diversion (e.g., ureterosigmoidostomy, ileal conduit)
- Acidosis of chronic renal failure (develops when GFR <sup>2</sup>20 to 30 mL/min)
- Excessive administration of acid load via chloride salts (NaCl, HCl, NH<sub>4</sub>Cl, lysine HCl, CaCl<sub>2</sub>, MgCl<sub>2</sub>)

## DIAGNOSTIC TESTS & INTERPRETATION

Electrolytes reveal hyperchloremic metabolic acidosis.

- Plasma anion gap normal (anion gap =  $\text{Na} - [\text{Cl} + \text{HCO}_3]$ ). Normal values (in mEq/L) depend on analyzer used: infants/children 5 to 15; adolescents/adults 4 to 12) (6). Must increase calculated anion gap by 2.5 mEq/L for each 1 g/dL decrease in **albumin** below 4 g/dL
- Plasma  $\text{K}^+$ : Low in type I (if due to impaired distal  $\text{H}^+$  secretion/increased  $\text{H}^+$  back leak), type II; high in type IV, type I (if due to impaired distal  $\text{Na}^+$  reabsorption)
- Plasma  $\text{HCO}_3$  (in untreated RTA): type I: <10 to 20 mEq/L; type II: 12 to 18 mEq/L (1); type IV: >17 mEq/L
- BUN/Cr normal or near normal (rules out renal failure as cause of acidosis)
- Urinalysis: Urine pH inappropriately alkaline (>5.5) despite metabolic acidosis in type I; also in type II if  $\text{HCO}_3$  above reabsorptive threshold (12 to 18 mEq/L)
- Urine culture: Rule out UTI with urea-splitting organism (may elevate pH) and chronic infection.
- Urine anion gap (UAG; urine  $[\text{Na}^+ + \text{K}^+] - \text{Cl}^-$  on a random specimen): reflects unmeasured urine anions, so inversely related to urine  $\text{NH}_4^+$  (or acid) excretion. Positive UAG in an acidemic patient indicates impaired renal acid excretion. Urine  $\text{Na}^+ >25$  mEq/L required for accurate interpretation of UAG. Results tend to be
  - Negative in  $\text{HCO}_3$  losses due to diarrhea, UTI caused by urea-splitting organisms, and other extrarenal causes of nonanion gap metabolic acidosis
  - Variable in type II RTA
  - Positive in type I RTA (7), type IV RTA
  - Positive in impaired acid excretion due to renal failure

---

P.903

- Urine calcium
  - High in type I
  - Typically normal in type II
- Drugs that may alter lab results
  - Diuretics
  - Sodium bicarbonate (and other alkali)
  - Cholestyramine

## *Initial Tests (lab, imaging)*

Serum electrolytes; consider urinalysis, urine culture.

## *Diagnostic Procedures/Other*

- Helpful to measure urine pH on fresh sample with pH meter for increased accuracy instead of dipstick. Pour film of oil over urine to avoid loss of CO<sub>2</sub> if pH cannot be measured quickly.
- Urine NH<sub>4</sub><sup>+</sup> excretion (anion gap only provides a qualitative estimate)
- Urinary acidification (impaired in type I RTA) can be assessed by oral administration of furosemide and fludrocortisone; patients with type I RTA unable to reduce urine pH to <5.3 (8)
- Fractional excretion of HCO<sub>3</sub> > 15% during HCO<sub>3</sub> infusion (type II RTA) (1)

## *Test Interpretation*

- Nephrocalcinosis
- Nephrolithiasis
- Rickets
- Osteomalacia, osteopenia
- Findings of an underlying disease causing RTA

## **TREATMENT**

### *MEDICATION*

#### *First Line*

- Provide oral alkali to raise serum HCO<sub>3</sub> to normal. Start at a low dose and increase until HCO<sub>3</sub> is normal. Give as sodium bicarbonate (7.7 mEq NaHCO<sub>3</sub>/650 mg tab), sodium citrate (oral solution, 1 mEq HCO<sub>3</sub> equivalent/mL), sodium/potassium citrate (oral solution), or potassium citrate (tablet, powder, or oral solution: 2 mEq K/mL, 2 mEq HCO<sub>3</sub>/mL), depending on need for potassium.
- Type I RTA: Typical doses 1 to 2 mEq/kg/day (in adults), 3 to 4 mEq/kg/day (in children) PO alkali divided 3 to 4 times per day (require much higher doses if HCO<sub>3</sub> wasting is present). May

require  $K^+$  supplementation

- Type II RTA: Typical doses 10 to 15 mEq/kg/day alkali, divided 4 to 6 times per day. Very difficult to restore plasma  $HCO_3^-$  to normal, as renal  $HCO_3^-$  losses increase once plasma  $HCO_3^-$  is corrected above resorptive threshold. Exogenous  $HCO_3^-$  increases  $K^+$  losses, requiring supplemental  $K^+$ . Often need supplemental  $PO_4$  and vitamin D due to proximal  $PO_4$  losses. May add thiazide diuretic to induce mild hypovolemia, which increases proximal  $Na^+/HCO_3^-$  reabsorption
- Type IV RTA: Avoid inciting medications; restrict dietary  $K^+$ . May augment  $K^+$  excretion with loop diuretic, thiazide diuretic, or Kayexalate. Correcting hyperkalemia increases activity of the urea cycle, augmenting renal ammoniogenesis and adding substrate for renal acid excretion. If necessary, 1 to 5 mEq/kg/day alkali divided 2 to 3 times per day. If mineralocorticoid deficiency, fludrocortisone: 0.1 to 0.3 mg/day
- Precautions
  - Sodium-containing compounds will increase urinary calcium excretion, potentially increasing the risk of nephrolithiasis.
  - Mineralocorticoids and sodium-based alkali may lead to hypertension and/or edema.
  - Aluminum-containing medications (antacids, sucralfate) should be avoided if solutions containing citric acid are prescribed because citric acid increases aluminum absorption.
  - Sodium bicarbonate may cause flatulence because  $CO_2$  is formed, whereas citrate is metabolized to  $HCO_3^-$  in the liver, avoiding gas production.

## *Second Line*

Thiazide diuretics may be used as adjunctive therapy in type II RTA (after maximal alkali replacement) but are likely to further increase urinary  $K^+$  losses.

## ***SURGERY/OTHER PROCEDURES***

If distal RTA is due to obstructive uropathy, surgical intervention may be required.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Generally managed as outpatient; inpatient if acidosis severe, patient unreliable, emesis persistent, or infant with severe failure to thrive

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- Electrolytes 1 to 2 weeks following initiation of therapy, monthly until serum  $\text{HCO}_3$  corrected to desired range, then as clinically indicated
- Monitor underlying disease as indicated.
- Poor compliance common due to 3 to 6 times per day alkali dosing schedule

#### *DIET*

Varies based on serum  $\text{K}^+$  level and volume status

### PATIENT EDUCATION

- National Kidney & Urologic Diseases Information Clearinghouse, Box NKUDIC, Bethesda, MD 20893, 301-468-6345: <http://www.kidney.niddk.nih.gov/>
- National Kidney Foundation: <https://www.kidney.org/>

### PROGNOSIS

- Depends on associated disease; otherwise, good with therapy
- Transient forms of all types of RTA may occur.

### COMPLICATIONS

- Nephrocalcinosis, nephrolithiasis (type I)
- Hypercalciuria (type I)
- Hypokalemia (type I, type II if given bicarbonate)
- Hyperkalemia (type IV, some causes of type I)
- Osteomalacia (type II due to phosphate wasting), osteopenia (due to buffering of acid in bone)

## Codes

&NA;

### ICD10

N25.89 Oth disorders resulting from impaired renal tubular function

## Clinical Pearls

&NA;

- Consider RTA in cases of normal anion gap metabolic acidosis with normal/near-normal renal function.

- Type I RTA: urine pH  $>5.5$  in setting of acidemia; positive urine anion gap; acidemia can be severe.
- Type II RTA: urine pH  $<5.5$  unless  $\text{HCO}_3^-$  raised above reabsorptive threshold (12 to 18 mEq/L)
- Type IV RTA: most common subtype; hyperkalemia; urine pH  $< 5.5$ ; acidemia usually mild
- Treatment includes avoidance of inciting causes, provision of oral alkali ( $\text{HCO}_3^-$  or citrate), and measures to supplement (type II, many type I) or restrict (type IV) potassium.

# Respiratory Distress Syndrome, Acute (ARDS)

Muhammad Imran Khan, MD

Najm Hasan Siddiqui, MD

## BASICS

### DESCRIPTION

- ARDS is an acute, diffuse, inflammatory lung injury that leads to increased pulmonary vascular permeability, increased lung weight, and a loss of aerated tissue (1) with clinical hallmarks of severe hypoxemia and bilateral pulmonary infiltrates.
  - Absence of left atrial hypertension (HTN)
  - By consensus,  $\text{PaO}_2/\text{FiO}_2 < 200$
  - Most severe form of acute lung injury
- System(s) affected: pulmonary; cardiovascular
- Synonym(s): shock lung; wet lung; noncardiac pulmonary edema

### EPIDEMIOLOGY

#### Incidence

ARDS: 10.1 to 86.2 cases/100,000 annually (2)

### ETIOLOGY AND PATHOPHYSIOLOGY

Three phases

- Acute exudative phase: characterized by profound hypoxia and associated with inflammation with infiltration of inflammatory and proinflammatory mediators and diffuse alveolar damage
- Fibrosing alveolitis phase: coincides with recovery or after  $\div 1$  to 2 weeks; patients continue to be hypoxic and have increased dead space and decreased compliance
- Resolution may require 6 to 12 months.
- Several mediators are involved in the initiation and perpetuation of ARDS.
  - Cytokines

- Complement activation
- Coagulation activation
- Platelet-activating factor
- Oxygen free radicals
- Lipoxygenase pathways
- Neutrophil proteases
- Nitric oxide
- Endotoxin
- Cyclooxygenase pathway products
- Systemic inflammatory response with activation of the previous mediators can occur with direct or indirect injury to the lung.
  - Direct
    - Aspiration
    - Pulmonary infections
    - Air, fat, or amniotic fluid emboli
    - Near-drowning
    - Pulmonary contusion
    - Inhalation of toxic gases and dusts
  - Indirect
    - Sepsis
    - Shock
    - Transfusion
    - Trauma
    - Overdose
    - Pancreatitis, severe
    - Eclampsia

## *RISK FACTORS*

- Severe infection (localized or systemic) most common

- Aspiration of gastric contents
- Shock
- Infection
- Trauma with or without lung contusion
- Pneumonia
- Toxic inhalation
- Pancreatitis
- Fat embolism
- Near drowning
- Multiple blood transfusions

## **GENERAL PREVENTION**

No effective measures have been identified.

## **COMMONLY ASSOCIATED CONDITIONS**

- Severe sepsis
- Trauma
- Shock

## **DIAGNOSIS**

### **HISTORY**

- No history of heart disease
- Precipitating event (see “Commonly Associated Conditions”): abrupt onset of respiratory distress

## **PHYSICAL EXAM**

- Tachypnea and tachycardia during the first 12 to 24 hours; respiratory distress
- Lethargy, obtundation
- Flat neck veins
- Hyperdynamic pulses

- Physiologic gallop
- Absence of edema
- Moist, cyanotic skin
- Manifestations of underlying disease

## ***DIFFERENTIAL DIAGNOSIS***

- Left ventricular failure
- Interstitial and airway diseases
- Hypersensitivity pneumonitis
- Veno-occlusive disease
- Mitral stenosis: intravascular volume overload
- Toxic shock syndrome

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Arterial blood gases (ABGs) show evidence of severe hypoxemia.
- $\text{PaO}_2/\text{FiO}_2 < 200$
- ECG: sinus tachycardia; nonspecific ST-T-wave changes
- Pulmonary artery wedge pressure (PAWP)  $< 15$  mm Hg
- Cardiac index  $> 3.5$  L/min/m<sup>2</sup>
- Chest x-ray (CXR): normal heart size; fluffy, bilateral infiltrates; air bronchograms common
- Chest CT scan: diffuse interstitial opacities and bullae

### ***Follow-Up Tests & Special Considerations***

- Serial blood gases
- Monitor for and treat multisystem organ failure when it occurs.
- Serial CXRs

### ***Diagnostic Procedures/Other***

Invasive monitoring of vital signs, cardiac output, and PAWP has been questioned by large clinical

trials.

## *Test Interpretation*

- Lungs show exudative, early proliferative or late proliferative phases.
- Interstitial and alveolar edema is present.
- Inflammatory cells and erythrocytes spill into the interstitium and the alveolus.
- Type 1 cells are destroyed, leaving a denuded basement membrane.
- Protein-rich fluid fills the alveoli.
- Type 2 alveolar cells initially appear unaltered.
- Type 2 cells begin to proliferate within 72 hours of initial insult and cover the denuded basement membrane.
- Aggregates of plasma proteins, cellular debris, fibrin, and surfactant remnants form hyaline membranes.
- Over the next 3 to 10 days, alveolar septum thickens by proliferating fibroblasts, leukocytes, and plasma cells.
- Capillary injury begins to occur.
- Hyaline membranes begin to reorganize.
- Fibrosis becomes apparent in respiratory ducts and bronchioles.

## **TREATMENT**

### *GENERAL MEASURES*

- Ensure adequate oxygenation.
- Ventilatory support generally requires endotracheal intubation and use of positive end-expiratory pressure (PEEP) (3)[A].
- Provide appropriate cardiorespiratory monitoring.
- Fluid management

### *MEDICATION*

- No single drug or combination of drugs prevents or treats full-blown ARDS. Treatment is supportive while addressing the underlying cause.

Supplemental oxygen

- Ventilatory support
  - Most often requires endotracheal intubation with emphasis on lower tidal volumes per weight and optimization of PEEP
  - High-frequency oscillation ventilation seems not to increase the risk of barotrauma or hypotension and reduces the risk of oxygenation failure, it does not improve survival in adult ARDS patients (4)[A].

## ISSUES FOR REFERRAL

- All patients with ARDS should be cared for in an ICU with appropriately trained staff.
- Pregnant patients with ARDS also should be followed by a high-risk perinatologist or obstetrician.

## ADDITIONAL THERAPIES

- Inotropic agents: dobutamine to maintain adequate cardiac output after appropriate fluid resuscitation fails to restore perfusion
- Corticosteroids: Short-term use during the acute phase has not been shown to be effective. However, prolonged methylprednisolone treatment accelerates the resolution of ARDS, improving a broad spectrum of interrelated clinical outcomes and decreasing hospital mortality and healthcare utilization (5)[A].
- Vasodilators: Inhaled nitric oxide (INO) is not recommended for patients with ARDS. INO results in a transient improvement in oxygenation but does not reduce mortality and may be harmful (6)[A].
- Pulmonary surfactant: successful in neonatal respiratory distress syndrome; investigational outside this age group
- Inhaled  $\beta_2$ -agonists may be helpful during the resolution phase.

---

P.905

- There is no current evidence to support or refute the routine use of aerosolized prostacyclin for patients with ARDS (7)[A].
- There is no effect on mortality with granulocytemacrophage colony-stimulating factor, neutrophil elastase inhibitors, intravenous salbutamol, surfactant, or N-acetylcysteine (8)[A].
- Early use of neuromuscular-blocking agent treatment of patients with severe sepsis and severe ARDS cannot only improve the severity but also reduce 21-day mortality (9)[A].
- Antioxidants (e.g., Procyteine) have produced conflicting results.

- Activated protein-C may be helpful in patients with sepsis.
- Deep vein thrombosis (DVT) prophylaxis
- Ulcer prophylaxis

### *Pregnancy Considerations*

Supportive care while identifying the underlying cause of ARDS continues to be important in the management of pregnant women with ARDS. However, fetal well-being, possible need for delivery, and physiologic changes associated with pregnancy must be considered.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

All patients with ARDS should be managed in an ICU setting.

- Consider prone positioning.
- Identify and treat underlying condition.
- Circulatory support, adequate fluid volume, and nutritional support
- Supplemental oxygen
- Monitoring blood gases, pulse oximetry, bedside pulmonary function test
- Support ventilation using lung-protective strategies and PEEP.
- Monitor for systemic hypotension and hypovolemia without fluid overload.
- BP support, if necessary
- Vasopressor agents
- Fluid management with IV crystalloid solutions while monitoring pulmonary status
- Pulmonary catheter pressure monitoring
- Treat underlying disease process.
- Prevent complications.

### *IV Fluids*

- Maintain the intravascular volume at the lowest level consistent with adequate perfusion (assessed by metabolic acid-base balance and renal function).
- If perfusion is inadequate after restoration of intravascular volume (e.g., septic shock), vasopressor therapy is indicated.

- Increase oxygen content with packed erythrocyte transfusions as necessary.
- Provide appropriate nutritional support with enteral or parenteral nutrition.
- Steroid therapy

## *Nursing*

May include any or all of the following:

- Skin, eye, and mouth care
- DVT prophylaxis
- GI prophylaxis
- Suctioning
- Ensure adequate level of sedation and/or paralysis while on mechanical ventilation.
- Oxygen supplementation
- Nebulizer therapy
- Chest physiotherapy
- Tracheostomy care
- Explain all procedures to patient and family; reduce anxiety.

## *Discharge Criteria*

- Supplemental oxygen
- Nutrition counseling
- Family monitoring of signs and symptoms of respiratory distress

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- Vital capacity and static lung compliance are important measures of lung mechanics.
- Daily labs are needed until the patient is no longer critical.
- CXRs to assess endotracheal tube placement, the presence of progressing infiltrates, catheter placement, and complications of mechanical ventilation (e.g., air leaks)

- A Swan-Ganz catheter to assess oxygen delivery, oxygen consumption, and cardiac output may be helpful but has not been shown to improve survival.

## DIET

- Nutritional support
- Conservative fluid management shortens ventilator and ICU time but does not affect survival.

## PATIENT EDUCATION

ARDS support center and brochure titled "Learn About ARDS": [www.ards.org](http://www.ards.org)

## PROGNOSIS

- Mortality rate is 43% (10).
- Survivors may have pulmonary sequelae with mild abnormalities in oxygenation, diffusion, and lung mechanics, as well as some pulmonary symptoms of cough and dyspnea.
- The prognosis worsens with elevated cardiac troponin-T levels in ARDS patients (11).

## COMPLICATIONS

- Permanent lung disease
- Oxygen toxicity
- Barotrauma
- Superinfection
- Multiple organ dysfunction syndrome
- Death

## BASICS

### DESCRIPTION

- Neonatal respiratory distress syndrome (NRDS) is a serious disorder of prematurity with a clinical manifestation of respiratory distress.
- Pulmonary surfactants that are deficient at birth and an overly compliant chest wall cause diffuse lung atelectasis.
- System(s) affected: pulmonary
- Synonym(s): hyaline membrane disease; surfactant deficiency

### ALERT

A disorder of the neonatal period

### EPIDEMIOLOGY

#### *Incidence*

- Predominant age: 93% incidence in infants born at or before 28 weeks gestational age
- Inversely proportional to gestational age and birth weight
- Predominant sex: slight male predominance
- Eighth leading cause of infant death in United States in 2013: 13.3 infant deaths per 100,000 live births (1)
- Despite advances, survival of infants born before 25 weeks gestation is rare (2).

#### *Prevalence*

Common disorder in premature infants, especially those born <28 weeks gestation

### ETIOLOGY AND PATHOPHYSIOLOGY

- Structurally immature lungs and surfactant deficiency lead to diffuse atelectasis.

- Exposure to high  $\text{FiO}_2$  and barotrauma associated with mechanical ventilation trigger proinflammatory cytokines that further damage alveolar epithelium.
- Decreased lung compliance leads to alveolar hypoventilation and ventilation-perfusion mismatch.
- Impaired surfactant synthesis and secretion

## *Genetics*

No known genetic pattern

## ***RISK FACTORS***

- Premature birth
- Infants of diabetic mothers
- Perinatal asphyxia
- History of RDS in a sibling

## ***GENERAL PREVENTION***

- Prevention of premature birth with education and regular prenatal care
- Antenatal corticosteroids
- Manage any medical issues appropriately.
- Healthy behaviors including diet and exercise
- Avoid exposure to tobacco smoke, alcohol, and illegal drugs.

## **DIAGNOSIS**

### **HISTORY**

Preterm neonates with worsening respiratory distress beginning shortly after birth and progressing over first few hours of life.

## ***PHYSICAL EXAM***

- Tachypnea
- Grunting
- Nasal flaring

- Subcostal and intercostal retractions
- Decreased breath sounds
- Cyanosis

## ***DIFFERENTIAL DIAGNOSIS***

- Early-onset group B streptococcal pneumonia and/or sepsis
- Transient tachypnea of newborn
- Meconium aspiration pneumonia

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- CBC and blood culture to rule out sepsis and pneumonia
- Electrolytes: Monitor for hypoglycemia and hypocalcemia.
- Arterial blood gases (ABGs)
  - Hypoxemia (which responds to supplemental oxygen)
  - Features of respiratory and metabolic acidosis
- Chest x-ray (CXR):
  - Diffuse reticulogranular pattern (ground-glass appearance)
  - Air bronchograms
  - Low lung volumes

## ***Diagnostic Procedures/Other***

Echocardiogram: Consider if murmur is present to evaluate for patent ductus arteriosus (PDA) and contribution to lung disease due to L → R shunting.

## ***Test Interpretation***

- Macroscopically: uniformly ruddy, airless appearance of lungs
- Microscopically: diffuse atelectasis and hyaline membranes (eosinophilic and fibrinous membrane lining air spaces)

## **TREATMENT**

- Along with antenatal steroids, surfactants improve survival for preterm infants.

- Surfactants are now recommended routinely as early in the course of RDS as possible.

## GENERAL MEASURES

- Warm, humidified, oxygen-enriched gases if the neonate is ventilating effectively
- Continuous positive airway pressure (CPAP) if infant is active and breathing spontaneously (3) [A]
- Positive-pressure ventilation per ETT via conventional mechanical ventilator (CMV) or high-frequency oscillation ventilator (HFOV) if respiratory failure occurs (i.e., respiratory acidosis, apnea, or hypoxia despite nasal CPAP) (3)[A]
- Transcutaneous monitors to measure CO<sub>2</sub> tension as necessary
- Pulse oximetry
- Umbilical artery catheter placement for continuous BP monitoring and sampling ABGs

## MEDICATION

- Pulmonary surfactant (3)[A]
- Side effects: Bradycardia, hypotension, airway obstruction/endotracheal tube blockage with administration; rapid changes in tidal volume due to increased compliance can cause a pneumothorax and small risk of pulmonary hemorrhage.

P.907

- Precautions: Transient adverse effects seen with the administration of surfactant may require stopping administration and alleviating situation; may proceed with dosing when stable
- Contraindications: presence of congenital anomalies incompatible with life beyond neonatal period; infant with laboratory evidence of lung maturity
- Perform frequent clinical and laboratory checks so that oxygen and ventilatory support can be modified to respond to respiratory changes (3)[A].

## ISSUES FOR REFERRAL

Comorbid conditions associated with prematurity may require consultation during the course of the infant's NICU admission, including PDA (cardiology consult), necrotizing enterocolitis (NEC) (gastroenterology), retinopathy of prematurity (ROP) (ophthalmology), etc.

## ADDITIONAL THERAPIES

Treat associated problems of prematurity.

# *INPATIENT CONSIDERATIONS*

## *Admission Criteria/Initial Stabilization*

All neonates with respiratory distress require evaluation, monitoring, and treatment in a NICU; treatment may be required in the delivery room.

## *IV Fluids*

- To maintain blood pressure and perfusion, when necessary
- To provide optimal fluid balance, provide nutritional support.

## *Nursing*

- Supportive care
- Thermoneutral environment
- Respiratory monitoring
- Establish relationship with family to provide education and emotional support.

## *Discharge Criteria*

- Should have stable vital signs and pulse oximetry before discharge
- Medical home and support services should be in place.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

Following discharge, infants should be followed closely by their physicians to monitor growth and respiratory symptomatology.

## *DIET*

As clinically indicated

## *PATIENT EDUCATION*

- Educate parents regarding the risks in subsequent pregnancies.
- Advise parents regarding potential issues with chronic lung disease.
- For patient education materials favorably reviewed on this topic, go to Boston Children's Hospital Web site (<http://www.childrenshospital.org>) and search for respiratory distress

syndrome in the ÖMy Child HasÓ window.

## PROGNOSIS

Prognosis and outcome are highly dependent on gestational age and birth weight. Almost half of the infants in Jarjour study who were born at or <25 weeksÖ gestation had significant neurodevelopmental disabilities on short- and long-term follow-up.

## COMPLICATIONS

- Complications specific to NRDS
  - Pneumothorax
  - Chronic lung disease, bronchopulmonary dysplasia (BPD)
  - Pulmonary interstitial edema (PIE)
- Additional complications may occur related to therapeutic interventions and comorbid conditions.

## Codes

**&NA;**

### ICD10

P22.0 Respiratory distress syndrome of newborn

## Clinical Pearls

**&NA;**

- Surfactants are used routinely as early in the course of RDS as possible.
- If an infant has a murmur, consider an echocardiogram to rule out PDA and shunting.
- Prognosis and outcome are highly dependent on gestational age and birth weight.

# Respiratory Syncytial Virus Infection

Elizabeth C. McKeen, MD

## BASICS

Respiratory syncytial virus (RSV) is a medium-sized, membrane-bound ribonucleic acid (RNA) virus that causes acute respiratory tract illness in all ages, with the most clinically significant disease occurring in infants and young children.

## DESCRIPTION

A major cause of respiratory illness, either of the upper respiratory tract (URT) or of the lower respiratory tract (LRT/bronchiolitis)

- In adults, RSV causes URT infections (URTIs).
- In infants and children, RSV causes URTIs and LRT infections (bronchiolitis and pneumonia).

## Pediatric Considerations

- 90-95% of children are infected at least once by the age of 24 months; reinfection is common.
- Leading cause of pediatric bronchiolitis (50-90%)
- Premature infants are at increased risk for severe acute RSV infection.

## EPIDEMIOLOGY

- Seasonality: Highest incidence of RSV in the United States occurs between December and March.
- Morbidity: RSV infection leads to over 100,000 annual hospitalizations.
- Mortality: Deaths associated with RSV are uncommon. Children with complex chronic conditions account for the majority of deaths, and the relative contribution of RSV infection to their deaths is unclear (1)[B].

## ETIOLOGY AND PATHOPHYSIOLOGY

- RSV-induced bronchiolitis causes acute inflammation, edema, and necrosis of small airway epithelium, air trapping, bronchospasm, and increased mucus production.
- RSV develops in the cytoplasm of infected cells and matures by budding from the plasma

membrane.

- Infection spreads through droplets, either airborne or personal contact, that inoculate the nose of a susceptible individual

## *Genetics*

- A genetic predisposition to severe RSV infections may be associated with polymorphisms in cytokine and chemokine-related genes, including *CCR5*, *IL4*, and affiliated receptors, *IL8*, *IL10*, and *IL13*.
- Infants with transplacentally acquired antibody against RSV are not protected against infection but may have milder symptoms.

## *RISK FACTORS*

- Risk factors for severe disease
  - Prematurity
  - Age <12 weeks
  - Underlying cardiopulmonary disease
  - Immunodeficiency
- Other risk factors
  - Low socioeconomic status
  - Exposure to environmental air pollutants
  - Child care attendance
  - Severe neuromuscular disease
  - Adults: occupational exposure to young children, hospital staff, teachers, and daycare workers

## *GENERAL PREVENTION*

- Hand hygiene is the most important step to prevent the spread of RSV.
  - Alcohol-based rubs are preferred; an alternative is hand washing with soap and water (2) [B].
- Avoid exposure to passive tobacco smoke, especially in infants and children (3)[A].
- Isolate patients with proven or suspected RSV.

- Palivizumab (Synagis), a monoclonal antibody directed against the fusion (F) protein of RSV, is indicated as prophylaxis for:
  - Infants and children <24 months of age with
    - Chronic lung disease of prematurity requiring medical therapy within 6 months of the start of RSV season
    - Hemodynamically significant congenital heart disease
    - Congenital abnormalities of the airway or neuromuscular disease that compromises handling airway secretions
  - Infants born at  $\geq 28$  weeks gestation if they are <12 months of age at the start of the RSV season; prophylaxis should be maintained through the end of the RSV season.
  - Infants born at 29 to 32 weeks gestation if they are <6 months of age at the start of the RSV season; prophylaxis should be maintained through the end of the RSV season.
  - Infants born at 32 to 35 weeks gestation who are <3 months of age at the start of the RSV season or who are born during the RSV season if they have one of the following two risk factors:
    - Infant attends child care
    - $\geq 1$  more siblings or other children <5 years of age living permanently in the child's household
- Dosage: maximum of 5 monthly doses beginning in November or December at 15 mg/kg per dose IM
- Current palivizumab guidelines in the *Red Book*.

## COMMONLY ASSOCIATED CONDITIONS

- Asthma
- Otitis media
- Serious bacterial infection (SBI) in infants and children with concurrent RSV infection is rare.

## DIAGNOSIS

### ALERT

In most cases, diagnosis is clinical. Laboratory and radiologic studies are not routinely necessary (2)[B].

## HISTORY

- Rhinorrhea and upper respiratory congestion
- Difficulty feeding in infants (due to respiratory effort)
- Increased respiratory rate or signs of increased work of breathing (grunting, flaring, retracting)
- Wheezing
- Cough
- Fever
- History of prematurity, secondhand tobacco exposure, daycare, number and age of siblings
- Immunization history
- Family history of respiratory disease

## PHYSICAL EXAM

- Vital signs: fever, signs of increased work of breathing (tachypnea, grunting, flaring, retracting), pulse rate; pulse oximetry (fifth vital sign) to assess oxygenation
- Ear, nose, throat: rhinorrhea, dry mucous membranes (dehydration)
- Serous otitis or acute otitis; pulmonary: wheezing, crackles
- Skin turgor
- Serial examinations to assess status

## Pediatric Considerations

Young infants with bronchiolitis may develop apnea with increased risk of prolonged hospitalization, ICU admission, and mechanical ventilation.

## DIFFERENTIAL DIAGNOSIS

- Mild illness/URTI
  - Other respiratory viral infections rhinovirus, human metapneumovirus, influenza virus, human bocavirus
  - Allergic rhinitis
  - Sinusitis
- Severe illness/LRTI

Bronchiolitis

- Asthma
- Pneumonia
- Foreign body aspiration

## **DIAGNOSTIC TESTS & INTERPRETATION**

### **Initial Tests (lab, imaging)**

- Routine laboratory testing is not necessary.
  - If obtained, WBC count may be normal or elevated.
  - Virologic tests for RSV, despite high predictive value, rarely change management decisions or outcomes for patients with clinical bronchiolitis.
- Given the low risk of SBI, full septic workups are not necessary unless child appears toxic.
- Chest x-ray (CXR) does not predict disease severity or change patient outcomes but may be helpful if a patient does not improve as expected, if the severity of the disease requires further investigation, or if another diagnosis is suspected.
- When obtained, typical CXR findings include:
  - Hyperinflation and peribronchiolar thickening
  - Atelectasis
  - Interstitial infiltrates
  - Segmental or lobar consolidation

## **TREATMENT**

### **GENERAL MEASURES**

- Assess hydration status and ability to take fluids orally. Treat dehydration adequately with an oral or IV fluid, particularly in infants.
- Supplemental oxygen is indicated if pulse oximetry falls persistently <90% in previously healthy patients.

### **MEDICATION**

## First Line

No first-line medication for RSV infections; treatment is usually supportive; oxygen as needed

---

P.909

## Second Line

- Bronchodilators show small, short-term improvements in clinical scores, but this small benefit should be weighed against costs and adverse effects.
  - Bronchodilators do not improve oxygen saturation, reduce hospital admission after outpatient treatment, shorten the duration of hospitalization, or reduce the time to resolution of illness at home.
  - Routine use not recommended
- Nebulized epinephrine is superior to placebo for short-term outcomes for outpatients, particularly in the first 24 hours of care.
  - Epinephrine superior for outpatient clinical outcomes in acute bronchiolitis (4)[A].
- Glucocorticoids do not alter admissions or length of hospitalization (5)[A].
  - Some data suggest that the combination of dexamethasone and epinephrine may reduce outpatient admissions (5)[A].
- A recent study found that montelukast (Singulair) has no effect on the clinical course of acute bronchiolitis (6)[C].
- Ribavirin, a nucleoside analogue and antiviral agent, has not been shown to be efficacious, particularly in immunocompromised patients (7)[A].
- There is no current evidence that nebulized rhDNase changes clinical outcomes in children <24 months of age hospitalized with acute RSV bronchiolitis (8)[B].
- Reserve use of antibacterial agents for patients who have specific findings that suggest a coexisting SBI (9)[B].
- Nebulized 3% saline may reduce the length of stay and improve the clinical severity score in infants hospitalized with acute viral bronchiolitis (10)[A].

## ADDITIONAL THERAPIES

- Bulb suctioning of the nares may provide some comfort to infants and allow for easier feeding.
- Efforts are underway to develop a RSV vaccine (11)[C].

## Pediatric Considerations

Over-the-counter (OTC) cough and cold medications should not be used in children <6 years due to lack of efficacy and the risk of life-threatening side effects.

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

No complementary, alternative, or integrative therapies are of proven benefit in the prevention or treatment of RSV bronchiolitis.

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

- Clinical judgment of the patient's degree of respiratory distress is the most important consideration. Ill-appearing infants should be hospitalized.
- Significant respiratory distress, an oxygen requirement to keep SpO<sub>2</sub> >90%, and the inability to hydrate orally are indications for admission.
- Mechanical ventilation is required in about 5% of infants hospitalized with RSV and 20% of children with underlying congenital heart disease, chronic lung disease, or immunosuppression.

### ***IV Fluids***

See Treatment.

### ***Discharge Criteria***

No set criteria for discharge, patients should be recovering and demonstrate:

- Stable respiratory status with no oxygen requirement
- Ability to maintain oral intake and sustain hydration
- Home resources adequate to support necessary home therapies, including caretaker ability to clear the infant's airway with bulb suctioning if needed
- Adequate follow-up and patient education

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Primary care follow-up to ensure resolution

### ***PATIENT EDUCATION***

*Bronchiolitis and Your Child*, available at <http://familydoctor.org/familydoctor/en/diseases->

## PROGNOSIS

Most patients with RSV infection recover fully within 7 to 10 days. Reinfection is common.

### COMPLICATIONS

- Infants hospitalized for RSV may be at increased risk for recurrent wheezing and reduced pulmonary function, particularly during the 1st decade of life.
- Overall mortality for infants and children <24 months of age is <1%.
- Although the relationship between RSV and asthma is unclear, RSV bronchiolitis in infancy has been linked to subsequent asthma.

## Codes

&NA;

### ICD10

- B97.4 Respiratory syncytial virus causing diseases classd elswhr
- J06.9 Acute upper respiratory infection, unspecified
- J21.0 Acute bronchiolitis due to respiratory syncytial virus

## Clinical Pearls

&NA;

- RSV causes 50-90% of pediatric bronchiolitis.
- Hand sanitation is the primary step for preventing RSV in the general population.

- The diagnosis of RSV is clinical in most cases. Routine lab testing is not necessary.
- Treatment of RSV is usually supportive.
- Palivizumab should be used to prevent RSV in high-risk patients.

# Restless Legs Syndrome

Donald E. Watenpaugh, PhD

John R. Burk, MD

## BASICS

### DESCRIPTION

- Sensorimotor disorder consisting of a strong urge to move the legs, usually with paresthesia (1)[A]
- Symptoms emerge during inactivity.
- Movement relieves symptoms, but they soon recur with inactivity.
- Symptoms occur preferentially in the evening/night.
- Symptoms may involve the arms or be more generalized.
- Patient may also report involuntary leg jerks (1)[A].
- Associated with insomnia and/or functional impairment(s)
- Not solely accounted for by another disorder
- System(s) affected: musculoskeletal; nervous
- Synonym(s): Willis-Ekbom disease

### EPIDEMIOLOGY

#### *Incidence*

- Onset at any age; increases with age
- Predominant sex: male = female (nulliparous); female (parous) two times > male (2)[B]
- May increase in summer (warm) months

#### *Prevalence*

- 4-15% of Caucasian adults; underdiagnosed
- 1-3% in children and adolescents

- Increases with age
- Lower in non-Caucasians

## *Pregnancy Considerations*

10-30% prevalence; exacerbates existing restless legs syndrome (RLS)

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Primary (early-onset) RLS: subcortical dopamine deficiency/dysmetabolism
- Late-onset (often secondary) RLS:
  - Iron deficiency and associated conditions
  - Chronic extremity tissue pathology/inflammation
  - Medications
    - Most antidepressants (exceptions: bupropion and desipramine)
    - Dopamine-blocking antiemetics (e.g., metoclopramide, prochlorperazine)
    - Some antiepileptic agents (e.g., phenytoin)
    - Phenothiazine antipsychotics; donepezil
    - Theophylline and other xanthines
    - Antihistamines/over-the-counter (OTC) cold preparations (e.g., pseudoephedrine)
    - Adrenergics, stimulants

## *Genetics*

- Early-onset RLS heritability: ~50%
- Genetically heterogeneous
  - Susceptibility loci: 2p14, 2q, 6p21.2, 9p, 12q, 14q, 15q23, and 20p
  - Genes: *MEIS1*, *MAP2K5/LBXCOR1*, and *BTBD9*

## *RISK FACTORS*

- Family history (3,4)
- Aging
- Chronic inactivity

- Inadequate sleep
- Associated conditions (see "Commonly Associated Conditions")
- Certain medications (see "Etiology")

## GENERAL PREVENTION

- Regular physical activity/exercise
- Adequate sleep
- Avoid evening caffeine, alcohol, tobacco.
- Avoid late-day use of medications that cause RLS.

## COMMONLY ASSOCIATED CONDITIONS

- Periodic limb movements of sleep, insomnia, sleep walking, other parasomnias, delayed sleep phase
- Iron deficiency, renal disease/uremia/dialysis, gastric surgery, liver disease
- Parkinson disease, multiple sclerosis, peripheral neuropathy, migraine
- Orthopedic problems, arthritis, fibromyalgia
- Venous insufficiency/peripheral vascular disease, erectile dysfunction
- Pulmonary hypertension, lung transplantation, chronic obstructive pulmonary disease (COPD)
- ADHD, anxiety/depression, "sundowning"
- Pregnancy (especially if Fe- or folate-deficient)

## DIAGNOSIS

- Depends on history, yet often "difficult to describe"
- May go undiagnosed for years by multiple doctors

## HISTORY

- Signs/symptoms (see also "Description") (1)[A]
  - Limited to evening, night
  - Example descriptions: burning, achy, itching, antsy, "can't get comfortable"
  - Painful in ~35% of patients
  - Discomfort associated with overwhelming urge to move and relieved by

movement

- Urge to move may be the only “discomfort.”
- Movement frequency every 10 to 90 seconds (mean ~25 seconds)
- Some patients must get up and walk.
- May involve arms or, rarely, whole body
- Periodic movements in sleep in ~80% of patients.
- Insomnia, fatigue, anxiety
- Severity range: from rare, minor problem to daily severe impact on quality of life
- Early-onset RLS (before age 45 years) progresses slowly.
- Late-onset RLS (1)[A]
  - Sometimes secondary to other factors
  - Tends to progress more rapidly
  - May resolve to extent that cause(s) resolve

### ***Pediatric Considerations***

Consider child’s own words in describing symptoms and these additional supportive findings (1)[A]:

- Insomnia or sleep disturbance
- RLS in immediate biologic relative
- Periodic limb movements during sleep

### ***Geriatric Considerations***

For diagnosis in the cognitively impaired

- Rubbing or kneading the legs in evening
- Evening hyperactivity (foot tapping, pacing, fidgeting, tossing/turning in bed)

## ***DIFFERENTIAL DIAGNOSIS***

- Claudication: Movement does not relieve pain and may worsen it.
- Motor neuron disease fasciculation/tremor: no discomfort or circadian pattern
- Peripheral neuropathy: usually no circadian pattern; unresponsive to dopamine agonists
- Dermatitis/pruritus: movement only to scratch; no circadian pattern
- Sleep-related leg cramps: isolated and very painful muscle contracture
- Periodic limb movement disorder: no wakeful movements

- Sleep starts: isolated involuntary events
- Rhythmic movement sleep disorder: movement periodicity faster than RLS
- Growing pains: no urge to move or relief by movement; circadian pattern opposite RLS
- ADHD: no sleep disorders or complaints in diagnostic criteria

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Serum ferritin to assess for iron deficiency

### ***Diagnostic Procedures/Other***

- Sleep study helpful but not required
  - Frequent, periodic movements during wake
- Suggested immobilization test
  - Conducted before nocturnal polysomnography
  - Patient attempts to sit still in bed for 1 hour
  - >40 movements per hour suggests RLS.
- Ankle actigraphy for in-home use
- Electromyography, nerve conduction studies for peripheral neuropathy, radiculopathy

### ***Test Interpretation***

- Serum ferritin should be >75 ng/mL.
- Transferrin saturation should be >16%.

## **TREATMENT**

First-line treatments

- Prescribed daily exercise (3)[B]; adequate sleep
- Correct iron deficiency.
- Dopaminergic medications
- For secondary RLS, treat cause(s).
- Multiple possible causes are *not* mutually exclusive.

## GENERAL MEASURES

- If iron deficient, supplement:
  - 325 mg FeSO<sub>4</sub> TID
  - Repletion requires months.
- Daily exercise. However, avoid unusual activity that may exacerbate symptoms.
- Regular and replete sleep
- Hot bath and leg massage
- Warm the legs (long heavy socks, electric blanket).
- Intense mental activity (games, puzzles, etc.)
- Avoid exacerbating factors.

## MEDICATION

- Use minimum effective dose.
- Preferentially use longer-acting/extended-release options.
- Daytime sleepiness unusual with doses and timing for RLS
- Severe/refractory RLS may require combination therapy (4,5)[A].

---

P.911

### First Line

- Dopamine agonists (4,5)[A]; titrate every 3 days to minimum dose necessary to fully control symptoms:
  - Pramipexole (Mirapex): 0.125 to 0.5 mg 1 hour before symptoms; titrate by 0.125 mg
  - Ropinirole (Requip): 0.25 to 4 mg 1 hour before symptoms; titrate by 0.25 mg
  - Divide dose for evening and bedtime symptoms.
  - Transdermal rotigotine (Neupro): 1 to 3 mg/24 hours patch; initiate with 1 mg/day; titrate by 1 mg weekly
  - Avoid dopamine agonists in psychotic patients, particularly if taking dopamine antagonists.
  - Add a different class of medication before exceeding dopamine agonist recommended dose.
- Gabapentin enacarbil (Horizant): 600 mg every day ÷5:00 PM (4,5)[A]
- All other medications off-label

## *Second Line*

- Anticonvulsants (for comorbid neuropathy).
  - Pregabalin (Lyrica): 50 to 300 mg/day
  - Carbamazepine: 200 to 800 mg/day
- Opioids (low risk of tolerance/addiction at bedtime)
  - Hydrocodone: 5 to 20 mg/day
  - Tramadol: 50 mg/day
  - Oxycodone: 2.5 to 20 mg/day
- Benzodiazepines and agonists (for associated insomnia or anxiety)
  - Clonazepam (Klonopin): 0.5 to 3 mg/day
  - Temazepam, triazolam, alprazolam, zaleplon, zolpidem, and diazepam
- Dopamine agonists
  - Carbidopa-levodopa (Sinemet or Sinemet CR): 10/100 to 25/250; PRN for sporadic symptoms

## *Pregnancy Considerations*

- Initial approach: nonpharmacologic therapies, assess/correct iron deficiency
- Avoid medications class C or D.
- In 3rd trimester, may consider low-dose clonazepam or opioids (6)[B].

## *Pediatric Considerations*

- First-line treatment: nonpharmacologic therapies, assess/correct iron deficiency
- Low-dose clonidine or clonazepam may be considered.

## *Geriatric Considerations*

- Avoid medications that cause dizziness or unsteadiness.
- Many medications given to elderly cause/exacerbate RLS.

## *ISSUES FOR REFERRAL*

Severe, intractable symptoms

- Augmentation response to dopaminergic therapy
- Peripheral neuropathy; orthopedic problems
- Peripheral vascular disease; intransigent iron deficiency

## ***ADDITIONAL THERAPIES***

- Vitamin, mineral supplements: Ca, Mg, B<sub>12</sub>, folate
- Clonidine: 0.05 to 0.1 mg/day
- Baclofen: 20 to 80 mg/day
- Methadone: 5 to 10 mg/day
- Oxycodone PR-Naloxone PR: 10 or 5 mg/day
- Prescription or OTC hypnotics

## ***SURGERY/OTHER PROCEDURES***

For orthopedic, neuropathic, or leg vascular disease (laser ablation, sclerotherapy, etc.)

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Relaxis leg vibration device (FDA approved; see <http://www.sensorymedical.com>)
- Sequential pneumatic leg compression
- Enhanced external counterpulsation
- Compression stockings
- Acupuncture
- MicroVas therapy
- Near-infrared light (3)[B]

## ***INPATIENT CONSIDERATIONS***

- Control RLS after orthopedic procedures.
- Addition/withdrawal of medications affecting RLS (e.g., narcotics)
- Changes in medical status may require medication changes (e.g., Mirapex contraindicated in renal failure and Requip contraindicated in liver disease).

## *IV Fluids*

- Iron infusion when oral Fe fails or contraindicated.
- When NPO, consider IV opiates.

## *Nursing*

- Evening walks, hot baths, leg massage, and warming
- Sleep interruption risks prolonged wakefulness.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- At 2-week intervals until stable, then annually
- If taking iron, remeasure ferritin.
- If status changes, assess for associated conditions and medications.

#### *DIET*

Avoid evening caffeine and alcohol.

### *PATIENT EDUCATION*

- Willis-Ekbom Disease Foundation: [www.rls.org](http://www.rls.org)
- National Sleep Foundation: [sleepfoundation.org](http://sleepfoundation.org)
- American Academy of Sleep Medicine: <http://sleepeducation.com/>

### *PROGNOSIS*

- Early-onset: lifelong condition with no current cure
- Late-onset/secondary: may subside with resolution of precipitating factors
- Current therapies usually control symptoms

### **COMPLICATIONS**

- Vicious cycle between sleep loss from RLS and exacerbation of RLS by sleep loss

- Augmentation of symptoms from prolonged dopaminergic therapy
  - Symptoms increase in severity, occur earlier, and/or spread.
  - Higher doses increase risk.
  - Highest risk from daily levodopa or Sinemet
  - Iron deficiency increases risk.
  - Add alternative medication then slowly downtitrate dopamine agonist.
- Obsessive-compulsive or impulse-control disorders from dopamine agonists
- Iatrogenic RLS (from antidepressants, etc.)

## Codes

&NA;

### ICD10

G25.81 Restless legs syndrome

## Clinical Pearls

&NA;

- Insomnia with frequent tossing/turning and difficulty getting comfortable is often RLS.
- Many antidepressants, antipsychotics, antiemetics, and antihistamines cause or exacerbate RLS.
- Titrate medication for RLS, especially dopaminergics, only up to the minimum dose necessary to control symptoms.
- RLS may interfere with use of positive airway pressure to treat obstructive sleep apnea.
- RLS and other sleep disorders may cause ADHD.

# Retinal Detachment

Richard W. Allinson, MD

## BASICS

### DESCRIPTION

- Separation of the sensory retina from the underlying retinal pigment epithelium
- Rhegmatogenous retinal detachment (RRD): most common type; occurs when the fluid vitreous gains access to the subretinal space through a break in the retina (Greek *rhegma*, ῥεντός)
- Exudative or serous detachment: occurs in the absence of a retinal break, usually in association with inflammation or a tumor
- Traction detachment: Vitreoretinal adhesions mechanically pull the retina from the retinal pigment epithelium. The most common cause is proliferative diabetic retinopathy.
- System(s) affected: nervous

### EPIDEMIOLOGY

#### Incidence

- Predominant age: Incidence increases with age.
- Predominant sex: male > female (3:2)
- Per year: 1/10,000 in patients who have not had cataract surgery

#### Prevalence

After cataract surgery, 1-3% of patients will develop a retinal detachment.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Traction from a posterior vitreous detachment (PVD) causes most retinal tears. With aging, vitreous gel liquefies, leading to separation of the vitreous from the retina. The vitreous gel remains attached at the vitreous base, in the retinal periphery, resulting in vitreous traction that produces tears in the retinal periphery. There is an  $\div$ 15% chance of developing a retinal tear from a PVD.

- PVD associated with vitreous hemorrhage has a high incidence of retinal tears.
- Exudative detachment
  - Tumors
  - Inflammatory diseases (Vogt-Koyanagi-Harada disease, posterior scleritis)
  - Miscellaneous (central serous retinopathy, uveal effusion syndrome, malignant hypertension)
- Traction detachment
  - Proliferative diabetic retinopathy
  - Cicatricial retinopathy of prematurity
  - Proliferative sickle-cell retinopathy
- Penetrating trauma

## *Genetics*

- Most cases are sporadic.
- There is an increased risk of RRD if a sibling has been affected by this condition. The risk increases with higher levels of myopia in the family history.

## *RISK FACTORS*

- Myopia (>5 diopters)
- Aphakia or pseudophakia
  - In patients undergoing small-incision coaxial phacoemulsification with high myopia (axial length  $\geq 26$  mm), the incidence of retinal detachment is 2.7%.
- PVD and associated conditions (e.g., aphakia, inflammatory disease, and trauma)
- Trauma
- Retinal detachment in fellow eye
- Lattice degeneration: a vitreoretinal abnormality found in 6-10% of the general population
- Glaucoma: 4-7% of patients with retinal detachment have chronic open-angle glaucoma.
- Vitreoretinal tufts: Peripheral retinal tufts are caused by focal areas of vitreous traction.
- Meridional folds: Redundant retina usually is found in the supranasal quadrant.

## GENERAL PREVENTION

Patients at risk for retinal detachment should have regular ophthalmologic exams.

### *Geriatric Considerations*

- PVD
- Cataract surgery

### *Pediatric Considerations*

Usually associated with underlying vitreoretinal disorders and/or retinopathy of prematurity

## COMMONLY ASSOCIATED CONDITIONS

- Lattice degeneration
- High myopia
- Cataract surgery
- Glaucoma
- History of retinal detachment in the fellow eye
- Trauma

### *Pregnancy Considerations*

Preeclampsia/eclampsia may be associated with exudative retinal detachment. No intervention is indicated, provided hypertension is controlled. Prognosis is usually good.

## DIAGNOSIS

### HISTORY

- Sudden flashes (photopsia)
- Shower of floaters
- Visual field loss: "curtain coming across vision"
- Central vision will be preserved if the macula is not detached.
- Poor visual acuity (20/200 or worse), with loss of central vision when macula is detached.

## PHYSICAL EXAM

Slit-lamp exam

- Dilated fundus exam with binocular indirect ophthalmoscopy

## ***DIFFERENTIAL DIAGNOSIS***

Retinoschisis (splitting of the retina)

- Vitreous cells and vitreous hemorrhage are found rarely in the vitreous with retinoschisis, whereas they are seen commonly in RRD.
- Retinoschisis usually has a smooth surface and is dome-shaped, whereas RRD often has a corrugated, irregular surface.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Visual field testing: differentiates RRD from retinoschisis. An absolute scotoma is seen in retinoschisis, whereas RRD causes a relative scotoma.

### ***Initial Tests (lab, imaging)***

- US can demonstrate a detached retina and may be helpful when the retina cannot be visualized directly (e.g., with cataracts).
- Fluorescein dye leakage can be seen in exudative retinal detachment; caused by central serous retinopathy and other inflammatory conditions

### ***Test Interpretation***

- Elevation of the neurosensory retina from the underlying retinal pigment epithelium
- Elevation of retina associated with <sup>3</sup>1 retinal tears in RRD or elevation of the retina without tears in exudative detachment
- In 3-10% of patients with presumed RRD, no definite retinal break is found.
- Tenting of the retina without retinal tears in traction detachment
- Pigmented cells within the vitreous (Ötobacco dustÓ)

## **TREATMENT**

### ***GENERAL MEASURES***

- Not all retinal tears or breaks need to be treated:
  - Flap or horseshoe tears in symptomatic patients (e.g., patients with flashes or floaters) are

treated frequently.

- Operculated holes in symptomatic patients are treated sometimes.
- Atrophic holes in symptomatic patients are treated rarely.
- Lattice degeneration with or without holes within the lattice in an asymptomatic patient with prior retinal detachment in the fellow eye may be treated prophylactically.
- Flap retinal tears in asymptomatic patients frequently are treated prophylactically.
- Exudative detachments usually are managed by treating underlying disorder.
- Traction detachments usually are managed by observation. If the fovea is involved, a vitrectomy is needed.

## *MEDICATION*

### *First Line*

- Intraocular gases
  - Air
  - Perfluoropropane (C<sub>3</sub>F<sub>8</sub>)
  - Sulfur hexafluoride (SF<sub>6</sub>)
- Perfluorocarbon liquids
- Silicone oil
- Contraindications to intraocular gas: patients with poorly controlled glaucoma
- Precautions with intraocular gas: Expanding intraocular gas bubble increases intraocular pressure; therefore, avoid higher altitudes.
- Significant possible interactions with intraocular gas: Nitrous oxide used in general anesthesia can expand an intraocular gas bubble.

### *Second Line*

Steroids may cause worsening of central serous retinopathy.

## *SURGERY/OTHER PROCEDURES*

- Timing of repairs
  - Macula attached: within 24 hours. If the detachment is peripheral and does not have features suggestive of rapid progression (e.g., large and/or superior tears), repair can be

performed within a few days.

- Macula recently detached: within 10 days of development of a macula-off retinal detachment (1)[B]
  - Old macular detachment: elective repair within 2 weeks

---

P.913

- If a retinal break has led to the development of a retinal detachment, surgery is needed. Surgical options (and combinations) include the following:
  - Demarcation laser treatment
  - Pneumatic retinopexy: Head positioning is required postoperatively.
  - Scleral buckle
  - Vitrectomy
  - Perfluorocarbon liquids for giant tears (circumferential tears <sup>3</sup>90 degrees)
  - Silicone oil for complex repairs
- Anesthesia: local or general
- RRD may have >1 break. If any retinal break is not closed at the time of surgery, the surgery will fail.
- Additional surgery may be required if the retina redetaches secondary to a new retinal break or because of proliferative vitreoretinopathy (PVR).
- Adjuvant combination therapy using 5-fluorouracil (5-FU) and low-molecular-weight heparin (LMWH) may reduce the incidence of PVR in patients undergoing vitrectomy for RRD who are at a greater risk of developing PVR, such as patients with uveitis, but does not seem to be of benefit in cases of established PVR.
- If a vitreous hemorrhage is present, presumably from a retinal tear and the fundus cannot be well visualized, consideration can be given for early vitrectomy (2)[C].
- There is a trend toward primary vitrectomy in the management of RRD. Eyes undergoing pars plana vitrectomy (PPV) for primary RRD repair may not need the addition of a scleral buckle (3)[B].
- There is no statistical difference in the primary reattachment rate between eyes treated with PPV and scleral buckle for RRD in both phakic and pseudophakic/aphakic eyes (4)[A].
- Patients with RRD who are at high risk for PVR (retinal detachment in two or more quadrants, retinal tears >1 clock hour, preoperative PVR, or vitreous hemorrhage). PPV-scleral buckle was associated with higher rates of anatomical success compared to PPV alone (5)[B].

- There is a reduced incidence of intraoperative retinal tear formation using a transconjunctival cannulated PPV system compared to the standard 20-gauge system requiring suture closure.

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

- Recognition of condition is key (see "Diagnosis").
- Refer to an ophthalmologist for exam and treatment, if indicated.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Bed rest prior to surgery.
- Postoperatively, if intraocular gas has been used, the patient may need specific head positioning and should not travel to high altitudes.

### ***Patient Monitoring***

- Alert ophthalmologist if there is new onset of floaters or flashes, increase in floaters or flashes, sudden shower of floaters, curtain or shadow in the peripheral visual field, or reduced vision.
- Patients with acute symptomatic PVD should be reexamined by the ophthalmologist in 3 to 4 weeks. The development of a retinal detachment is unlikely if no retinal tears are present on reexamination in 3 to 4 weeks.
- If acute symptomatic PVD is associated with gross vitreous hemorrhage that interferes with complete visualization of the retinal periphery by indirect ophthalmoscopy, the patient should be reexamined at short intervals with indirect ophthalmoscopy until the entire retinal periphery can be observed.
- If the examiner is not certain whether the retina is detached in the presence of opaque medium, US should be performed.

### ***DIET***

NPO if surgery is imminent.

### ***PATIENT EDUCATION***

American Academy of Ophthalmology, 655 E. Beach Street, San Francisco, CA 94109-1336

# PROGNOSIS

- RRD
  - 90% of retinal detachments can be reattached successfully after 31 surgical procedures. Postoperative visual acuity depends primarily on the status of the macula preoperatively. Also important is the length of time between the detachment and the repair (75% of eyes with macular detachments of <1 week will obtain a final visual acuity of 20/70 or better).
  - 87% of eyes with a retinal detachment not involving the macula attain a visual acuity of 20/50 or better postoperatively. 37% of eyes with a detached macula preoperatively attain 20/50 or better vision postoperatively.
  - In 10-15% of successfully repaired retinal detachments not involving the macula preoperatively, visual acuity does not return to the preoperative level. This decrease is secondary to complications such as macular edema and macular pucker.
- Risk factors associated with primary RRD repair failure include choroidal detachment, significant hypotony, grade C-1 PVR, four detached quadrants, and large or giant retinal breaks (6)[B]. Additional risk factors associated with primary RRD repair failure include increased number of breaks and inferior location of retinal breaks (7)[B]. Tractional retinal detachment: When not involving the fovea, the patient usually can be observed because it is uncommon for these to extend into the fovea.
- Exudative retinal detachment
  - Management is usually nonsurgical.
  - The presence of shifting fluid is highly suggestive of an exudative retinal detachment. Fixed retinal folds, which are indicative of PVR, are seen rarely in exudative retinal detachment. If the underlying condition is treated, the prognosis generally is good.

## COMPLICATIONS

- PVR is the most common cause of failed retinal detachment repair; 10-15% of retinas that reattach initially after retinal surgery will redetach subsequently, usually within 6 weeks, as a result of cellular proliferation and contraction on the retinal surface.
- Partial or total loss of vision due to macular detachment and/or PVR
- Moderate to severe forms of PVR usually are treated with PPV and fluid-gas exchange. If a segmental scleral buckle was placed at the initial procedure, it may need to be revised.
- Primary retinectomy can be used in cases of PVR without a scleral buckle (8) [C].

Scleral buckles may erode the overlying conjunctiva and lead to an infection.

- Optic neuropathy after PPV for macula-sparing primary RRD

## See Also

&NA;

## Codes

**&NA;**

### ICD10

- H33.001 Unspecified retinal detachment with retinal break, right eye
- H33.019 Retinal detachment with single break, unspecified eye
- H33.20 Serous retinal detachment, unspecified eye

## Clinical Pearls

**&NA;**

- If a patient complains of the new onset of floaters or flashes of light, the patient should undergo a dilated eye exam to rule out a retinal tear or retinal detachment.
- There is an increased risk of retinal detachment after cataract surgery.
- PVR can result in redetachment of the retina after an initially successful repair.

# Retinopathy, Diabetic

Richard W. Allinson, MD

## BASICS

### DESCRIPTION

- Noninflammatory retinal disorder characterized by retinal capillary closure and microaneurysms. Retinal ischemia leads to release of a vasoproliferative factor, stimulating neovascularization on retina, optic nerve, or iris.
- Most patients with diabetes mellitus (DM) will develop diabetic retinopathy (DR). It is the leading cause of new cases of legal blindness among residents in the United States between the ages of 20 and 64 years.
- DR can be divided into three stages.
  - Nonproliferative (background)
  - Severe nonproliferative (preproliferative)
  - Proliferative
- System(s) affected: nervous

### *Geriatric Considerations*

Prevalence will increase, as population generally ages and patients with diabetes live longer.

### *Pregnancy Considerations*

- Pregnancy can exacerbate condition.
- Pregnant diabetic women should be examined in 1st trimester, then every 3 months until delivery.

### EPIDEMIOLOGY

#### *Incidence*

- Peak incidence of type 1, juvenile-onset DM is between the ages of 12 and 15 years.
- Peak incidence of type 2, adult-onset DM is between the ages of 50 and 70 years.

- Incidence of DR is directly related to the duration of diabetes.
- <10 years of age, it is unusual to see DR, regardless of DM duration

## *Prevalence*

- 6.6% of the U.S. population between ages of 20 and 74 years has DM.
- ÷25% of the diabetic population has some form of DR.
- Predominant age
  - Risk increases after puberty.
  - 2/3 of juvenile-onset diabetics who have had DM for at least 35 years will develop proliferative DR and will develop macular edema. Proportions are reversed for adult-onset diabetes.
- Predominant sex: male = female (type 1, juvenile-onset DM); female > male (type 2)

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Related to development of diabetic microaneurysms and microvascular abnormalities
- Reduction in perifoveal capillary blood flow velocity, perifoveal capillary occlusion, and increased retinal thickness at the central fovea in diabetic patients are associated with visual impairment in patients with diabetic macular edema.

## *RISK FACTORS*

- Duration of DM (usually >10 years)
- Poor glycemic control
- Pregnancy
- Renal disease
- Systemic hypertension (HTN)
- Smoking
- Elevated lipid levels associated with increased risk of retinal lipid deposits (hard exudates)
- Myopic eyes (eyes with longer axial length) have a lower risk of DR.

## *GENERAL PREVENTION*

- Monitor and control of blood glucose.

Schedule yearly ophthalmologic eye exams.

## COMMONLY ASSOCIATED CONDITIONS

- Glaucoma
- Cataracts
- Retinal detachment
- Vitreous hemorrhage
- Disc edema (diabetic papillopathy); may occur in type 1/type 2 DM

## DIAGNOSIS

### HISTORY

Diabetic patients should be encouraged to have an annual ophthalmologic exam because early changes are asymptomatic.

## PHYSICAL EXAM

- Eye exam: measurement of visual acuity and documentation of the status of the iris, lens, vitreous, and fundus
- Nonproliferative (background) DR
  - Microaneurysms
  - Intraretinal hemorrhage
  - Macular edema causing decrease in central vision
  - Lipid deposits
- Severe nonproliferative (preproliferative) DR
  - Nerve fiber layer infarctions (Cotton wool spots)
  - Venous beading
  - Venous dilatation
  - Intraretinal microvascular abnormalities
  - Extensive retinal hemorrhage
- Proliferative DR
  - New blood vessel proliferation (neovascularization) on the retinal surface, optic nerve, and

iris

- Visual loss caused by vitreous hemorrhage, traction retinal detachment

## GENERAL MEASURES

- The Diabetes Control and Complications Trial (DCCT) recommended that for most patients with insulin-dependent DM, blood glucose levels should be as close to the nondiabetic range as is safe to reduce the risk and rate of progression of DR.
  - In the DCCT, insulin-dependent DM patients were randomly assigned into either conventional or intensive insulin treatment. Conventional treatment consisted of one to two daily insulin injections, with daily self-monitoring of urine/blood glucose. Intensive treatment consisted of insulin administered <sup>33</sup> times daily by injection/an external pump, with self-monitored blood glucose levels measured at least 4 times per day.
  - The DCCT demonstrated that intensive insulin therapy reduced the risk of macular edema and retinal neovascularization. The benefit of intensive insulin therapy and the reduced risk of DR-associated microvascular complications persist for at least 10 years.
- In the DCCT, intensive insulin therapy was more effective in reducing the risk of progression of DR in the less advanced stages. However, advanced DR also benefited from the intensive insulin therapy. The Early Treatment Diabetic Retinopathy Study demonstrated that aspirin therapy did not prevent the development of proliferative DR or reduce the risk of visual loss associated with DR.
- Microvascular complications, including proliferative DR, are increased when blood sugar levels are <sup>3</sup>200 mg/dL.
- Poor glycemic control is associated with an increased risk both for development and progression of DR, regardless of the type of DM; that hyperglycemia itself is causative is not established, especially for type 2 DM.
- Cataracts are more common among those with DM. Try to delay cataract surgery in DM patients with retinopathy until the symptoms are severe. Cataract surgery can cause retinopathy to worsen and increase the risk for development of diabetic macular edema.
- HTN has a detrimental effect on DR and must be controlled.

## DIFFERENTIAL DIAGNOSIS

Other causes of retinopathy (e.g., radiation, retinal venous obstruction, HTN)

## DIAGNOSTIC TESTS & INTERPRETATION

## *Diagnostic Procedures/Other*

- Fluorescein angiography demonstrates retinal nonperfusion, retinal leakage, and proliferative DR.
- Optical coherence tomography (OCT) can be used to help detect diabetic macular edema by measuring retinal thickness.

## *Test Interpretation*

- Increased capillary permeability
- Microaneurysms
- Hemorrhages in retina
- Exudates in retina
- Capillary nonperfusion

## **TREATMENT**

### *MEDICATION*

- Treatment with the angiotensin-receptor blocker candesartan has been shown to result in regression of DR in some patients (1)[B].
- Nutritional antioxidant intake of vitamins C and E and of *β*-carotene has no protective effect on DR.
- Atorvastatin may reduce the severity of lipid deposits with clinically significant diabetic macular edema in type 2 DM and dyslipidemia.

### *SURGERY/OTHER PROCEDURES*

- Laser photocoagulation treatment: recommended for patients with proliferative DR and for those with clinically significant macular edema; destroys leaking blood vessels and areas of neovascularization
- The Diabetic Retinopathy Study demonstrated that panretinal photocoagulation reduced overall rate of severe visual loss from 15.9% in untreated eyes to 6.4% in treated eyes. In certain subgroups, the incidence of severe visual loss in untreated eyes was as high as 36.9% within 2 years.
- The Early Treatment Diabetic Retinopathy Study demonstrated that eyes with significant diabetic

macular edema benefited from focal laser treatment. Clinically significant diabetic macular edema (CSDME) is defined as the following:

- Thickening of the retina within 500  $\mu\text{m}$  of the center of the macula
  - Hard exudates within 500  $\mu\text{m}$  of the center of the macula associated with thickening of the adjacent retina
  - Zone of retinal thickening  $\geq 1$  disc area within 1 disc diameter of the center of the macula
- Patients with CSDME and high-risk proliferative disease can have simultaneous focal and panretinal photocoagulation without adversely affecting the visual outcome.
  - Vitrectomy may benefit some with diffuse macular edema. This may apply especially to eyes with vitreomacular traction found on OCT and with persistent CSDME.
  - Intravitreal triamcinolone may be used for DM-related macular edema that fails laser treatment. No long-term benefit of intravitreal triamcinolone relative to focal/grid photocoagulation in patients with CSDME. This is an off-label use (2)[C].
  - Ranibizumab, an antibody fragment that binds vascular endothelial growth factor (VEGF), can be used to treat CSDME when injected intravitreally. Ranibizumab 0.3 mg given monthly to treat CSDME resulted in improved vision and reduced central foveal thickness (3)[A]. It is indicated for diabetic macular edema (DME) and for DR in patients with DME.
    - Anti-VEGF therapy is the preferred method of treatment for visual impairment resulting from (DME). Anti-VEGF treatment results in superior clinical outcomes compared to laser photocoagulation for DME (4)[A].
    - The 5-year results suggest focal/grid laser treatment at the initiation of intravitreal ranibizumab injection (IRI) is no better than deferring laser treatment for  $\geq 24$  weeks in eyes with DME involving the central macula with vision impairment (5)[A].
    - Intravitreal ranibizumab treatment for diabetic macular edema may also improve DR severity and reduce the risk of DR progression (6)[A].
    - Monthly (IRI) can slow, but not completely prevent, retinal capillary closure in patients with DME (7)[B].
  - Bevacizumab, a full-length antibody that binds VEGF, can be used to treat CSDME when injected intravitreally. This is an off-label use.
    - Intravitreal bevacizumab and ranibizumab have comparable efficacy in treating DME (8)[C].
  - Aflibercept, a soluble decoy receptor for VEGF. Aflibercept 2 mg (0.05 mL) injected intravitreally every 4 weeks for the first 5 injections followed by 2 mg (0.05 mL) intravitreally once every 8 weeks. It is indicated for patients with DME and for DR in patients with DME.

- Intravitreal aflibercept injection (IAI) has demonstrated significant superiority in functional and anatomic endpoints over macular laser photocoagulation (9)[A].
- At worse levels of initial visual acuity (20/50 or worse) in patients with DME, IAI was more effective in improving vision than ranibizumab or bevacizumab (10)[A]. When the initial vision loss was mild (20/32 to 20/40) in patients with DME, there was no significant difference between aflibercept, ranibizumab, or bevacizumab (10)[A].
- Preoperative bevacizumab can be used as an adjuvant to vitrectomy for complications of proliferative DR. This is an off-label use:
  - At  $\pm$ 10 days after intravitreal injection of bevacizumab, the vascular component of proliferation is markedly reduced, and the contractile components are not yet very significant. Patients with dense fibrovascular proliferation need to be monitored closely for evidence of traction retinal detachment (11)[C].
- Intraocular steroid implants for DME. A dexamethasone implant and a fluocinolone acetonide implant. Complications of these implants include cataract and glaucoma.
- Vitrectomy: recommended for patients with severe proliferative DR, traction retinal detachment involving the macula, and nonclearing vitreous hemorrhage

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

Scheduled ophthalmologic eye exams

- Yearly follow-up if no retinopathy
- Every 6 months with background DR
- At least every 3 to 4 months with preproliferative DR
- Every 2 to 3 months with active proliferative DR

#### *DIET*

Follow prescribed diet for patients with diabetes.

### *PATIENT EDUCATION*

- Patient education should include regular ophthalmic exams.

- Stress importance of strict blood glucose control through diet, exercise, drugs/insulin, and monitoring of blood glucose.

## PROGNOSIS

If the condition is diagnosed and treated early in development, outlook is good. If treatment is delayed, blindness may result.

## COMPLICATIONS

- Repeated intravitreal injection of anti-VEGF therapy may increase the risk of sustained intraocular pressure elevation and the possible need for ocular hypotensive treatment (12)[A].
- Blindness

### ICD10

- E11.319 Type 2 diabetes mellitus with unspecified diabetic retinopathy without macular edema
- E10.319 Type 1 diabetes mellitus with unspecified diabetic retinopathy without macular edema
- E10.329 Type 1 diab w mild nonprlf diabetic rtnop w/o macular edema

# Clinical Pearls

**&NA;**

- Options for the treatment of diffuse macular edema include focal laser treatment, intravitreal triamcinolone, intravitreal ranibizumab, intravitreal bevacizumab, intravitreal aflibercept, intraocular steroid implants, and vitrectomy.
- High BP should be controlled to reduce the risk of diabetic eye complications.
- Blood glucose levels should be well controlled to help reduce the risk and rate of DR progression.
- Schedule yearly ophthalmologic eye exams.

# Reye Syndrome

Kattie Hoy, MD

## BASICS

### DESCRIPTION

- A serious, acute noninflammatory encephalopathy associated with cerebral edema and fatty infiltration of the liver classically noted in children taking aspirin during a viral infection (1,2)
- Occurs primarily in children and adolescents, with an average age of 6 years (2)
- Reye syndrome (RS) is typically biphasic, often initially presenting with symptoms of viral or bacterial infection (i.e., in order of association influenza A or B, varicella, parainfluenza, measles, adenovirus, coxsackieviruses, parechovirus, CMV, EBV, HIV, hepatitis A or B, *Mycoplasma*, and *Chlamydia*), 1 to 5 days without symptoms, followed by onset of severe vomiting, altered mental status, and signs of acute encephalopathy (2,3).
- RS is currently very rare since warning statements by the CDC and American Academy of Pediatrics in 1982 were issues for use of aspirin in children, followed by black box warning in 1986 against use of aspirin in children and teenagers with recent viral illness (4,5).
- System(s) affected: gastrointestinal, nervous, muscular, and cardiac (6)
- Synonym(s): white liver disease

### EPIDEMIOLOGY

#### Incidence

- Predominant age (1,2)
  - 3 months to 12 years, but can occur at any age
  - Peak incidence at 6 years of age
- Predominant sex: male = female (2)
- Currently very rare. In the United States, <0.1/100,000 annually since 1989 (Autret). Prior to issued warnings about aspirin use in children, the United States documented 555 case reports in 1980. Most recent U.S. statistics noted no >2 cases per year between 1994 and 1997 (1).
- Mortality rate 20-40%, male > female (5,7)

## ETIOLOGY AND PATHOPHYSIOLOGY

Specific etiology is unknown but appears to be secondary to multiple synergistic factors causing acute mitochondrial injury from significant inhibition of fatty acid oxidation limiting gluconeogenesis causing hypoglycemia, elevated ammonia, acute transaminitis, and hepatic fatty infiltration (1,8).

### Genetics

Possible genetic factors that lead to predisposition for development of RS but currently no known genetic pattern (3)

## RISK FACTORS

- Pediatric age group
- Prodromal illnesses
  - Viral: influenza A and B, varicella, parainfluenza, measles, adenovirus, coxsackievirus, parechovirus, EBV, CMV, HIV, hepatitis A and B, or rotavirus
  - Bacterial: *Mycoplasma*, *Chlamydia*, *Salmonella*, *Shigella* (3)
- Use of preparations containing aspirin, salicylates, and/or salicylamides (1).
- Other exogenous agents with less significant association: valproic acid, aflatoxin in Thailand, bongkredate in Indonesia, margosa oil in Southern Asia, unripe ackee fruit in Jamaica, hopentenate in Japan, and insecticides in Canada (1)

## GENERAL PREVENTION

- Avoid salicylates in children with viral illnesses because the drug appears to act as a cofactor in susceptible individuals (1).
- A physician should be consulted before giving any child aspirin or antinausea medicines (containing salicylates) during a viral illness, especially influenza A (5).
- Recognize early symptoms of the disease for prompt initiation of supportive treatment (7).

## DIAGNOSIS

RS is a diagnosis of exclusion (1).

- CDC diagnostic criteria (5)
  - Acute noninflammatory encephalopathy with an altered level of consciousness

- Hepatic dysfunction with liver biopsy showing fatty change or an over 3-fold increase in AST, ALT, and/or ammonia levels
- No other explanation for cerebral edema or hepatic abnormality
- Cerebral spinal fluid with white blood cells 8/mm<sup>3</sup> or fewer
- Brain biopsy showing cerebral edema without inflammation
- RS clinical staging system (5)
  - I: vomiting, somnolence, lethargy
  - II: confusion, delirium, combativeness, hyperreflexia, hyperventilation
  - III: obtundation, predominantly flexor motor responses, decorticate, intact pupillary reflex
  - IV: coma, seizures, predominant extensor motor responses, decerebrate posturing, fixed pupils
  - V: coma, flaccid paralysis, loss of deep tendon reflexes, seizures, respiratory arrest, isoelectric EEG, pupils unresponsive

## **HISTORY**

- Recent aspirin use
- Recent prodromal illness
- Sleepiness, lethargy, or confusion
- Sudden onset protracted vomiting

## **PHYSICAL EXAM**

- Hyperpnea, somnolence, altered mental status
- Various stages of neurologic deficits pending stage of syndrome
- Hepatomegaly usually present; icterus absent or only seen moderately; sometimes intracranial pressure elevation (3)[A]

## **DIFFERENTIAL DIAGNOSIS**

- Acute encephalopathy without hepatic abnormalities
  - Encephalitis
  - Meningitis
  - Drug overdose

- Poisoning
- Psychiatric illness
- Diabetes mellitus
- Reye-like syndrome: acute toxic encephalopathy with hepatic abnormalities due to either metabolic disorders or drug or toxin ingestions, including the following (3):
  - Inherited metabolic disorders: organic acidurias with defects in hepatic fatty acid oxidation; fatty acid metabolism defects
  - Acyl-CoA dehydrogenase, carnitine deficiency
    - Urea cycle defects
    - Carbamoyl phosphate synthetase, ornithine transcarbamylase
    - Fructosemia
  - The most commonly diagnosed metabolic disorder in association with RS is medium-chain acylcoenzyme A dehydrogenase deficiency.
  - Toxin ingestions

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Over 3-fold elevations of AST, ALT, and/or ammonia (5)
- Hypoglycemia (8)
- Possible coagulopathy with abnormal bleeding time, PT, PTT, and/or platelet count (7)
- Mixed respiratory alkalosis and metabolic acidosis (3)
- MRI findings of cerebral edema with signal alteration in many areas including brainstem, thalami, temporal lobe, parasagittal cortex, cerebellar, and subcortical white matter (9)[C]

## **Follow-Up Tests & Special Considerations**

Usually complete resolution of lesions on T2-weighted images except in areas of thalamus, which can take many months to resolve (9)[C]

### ***Diagnostic Procedures/Other***

- Lumbar puncture with CSF pressure measurement (5)
- Liver biopsy (5,7)
- Brain biopsy (5)

## Test Interpretation

- Liver biopsy notes variably sized multiple intracellular and extracellular vacuoles representing microvesicular steatosis. Hepatocytes also display nuclear pyknosis and fragmentation. The mitochondria are distorted with destroyed cristae (10).
- Brain biopsy with cerebral edema without inflammation (5)
- Increased CSF pressure without pleocytosis ( $<8$  leukocytes/mm<sup>3</sup>) (5)

## Pediatric Considerations

- It is essential to make the diagnosis as early as possible and start appropriate supportive measures immediately as progression to more severe stage is associated with higher mortality (7).
- Must investigate for inborn errors of metabolism in any patient suspected to have RS as well as other etiology due to RS being a diagnosis of exclusion (1).

P.917

## TREATMENT

### GENERAL MEASURES

- Supportive care dictated by the severity of illness (5)[A]
- IV glucose and frequent monitoring of serum glucose to treat hypoglycemia (7)[B].
- Hyperventilation, mannitol, glycerol, and corticosteroids to control intracranial pressure (7)[B]
- Vitamin K, fresh frozen plasma, and platelets as needed for treatment of coagulopathy (7)[B]
- Mechanical ventilation as needed
- Dialysis to remove toxins and toxic metabolites (7)[B]

### MEDICATION

- All treatment is supportive and may include the following (7)[B]:
  - Glucose 10-15% IV
  - Vitamin K
  - For increased intracranial pressure
    - Mannitol

- Dexamethasone
- Glycerol
- Contraindications: NSAIDs such as diclofenac and mefenamic acid may complicate clinical picture so should not be used (3)[A].
- Precautions: Mannitol and poor renal output may result in vascular overload and pulmonary edema.
- Resveratrol used in animals studies showed protection against the oxidative stress occurring in RS but has yet been researched in clinical practice (10).

## ***SURGERY/OTHER PROCEDURES***

Liver transplant (11)[C]

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Medical emergency requiring immediate hospitalization and frequent monitoring, often in an intensive care setting (3)[A]

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Complete bed rest until recovery is noted and able to return to normal activity as tolerated.

### ***Patient Monitoring***

Depends on specific residual effects. may require care of physicians; nurses; psychologists; and/or physical, occupational, and/or speech therapists (7)[B]

### ***DIET***

NPO during the acute phase

## ***PATIENT EDUCATION***

- National Reye Syndrome Foundation, P.O. Box 829, Byron, OH 43506-0829 (800) 233-7393; [www.reyessyndrome.org](http://www.reyessyndrome.org)
- National Institutes of Health: [http://www.ninds.nih.gov/disorders/reyes\\_syndrome/reyes\\_syndrome.htm](http://www.ninds.nih.gov/disorders/reyes_syndrome/reyes_syndrome.htm)

## PROGNOSIS

- Overall prognosis is related to degree of cerebral edema and ammonia level on admission, correlated with severity of stage (7)[B].
- Outcomes range from a mild illness without progression and complete resolution to a critical illness with significant lasting sequelae or death (7)[B].
- Possible neurologic sequelae include brain damage and disability, problems with attention, concentration, speech, language, and fine and gross motor skills.
- Sequelae are more common with higher stages.

## COMPLICATIONS

- Aspiration pneumonia
- Respiratory failure
- Cardiac dysrhythmia/arrest
- Inappropriate vasopressin excretion
- Diabetes insipidus
- Cerebral edema
- Seizures
- Death

## Codes

&NA;

### ICD10

G93.7 Reye's syndrome

## Clinical Pearls

&NA;

- RS is a rare, acute noninflammatory encephalopathy largely affecting children and adolescents.
- Associations include antecedent viral/bacterial infection and aspirin use.
- Most current cases of RS are actually Reye-like syndromes, caused by an inborn error of metabolism or a toxin exposure.
- All current treatment is supportive.
- Acetaminophen is first choice to treat fever followed by ibuprofen, in children.
- Prognosis is related to the degree of cerebral edema and ammonia level on admission and ranges from complete resolution to persistent neurologic sequelae or death.

# Rh Incompatibility

Kirsten A. Winnie, MD

Jennifer G. Chang, MD

## BASICS

### DESCRIPTION

- Antibody-mediated destruction of red blood cells (RBCs) that bear Rh surface antigens in individuals who lack the antigens and have become isoimmunized (sensitized) to them
- System(s) affected: hematologic/lymphatic/immunologic
- Synonym(s): Rh isoimmunization; Rh alloimmunization; Rh sensitization

### EPIDEMIOLOGY

#### *Incidence*

Predominant age and sex: affects fetuses/neonates of isoimmunized, childbearing females

### ETIOLOGY AND PATHOPHYSIOLOGY

- Circulating antibodies to Rh antigens (transplacentally transferred antibodies in the case of a fetus/newborn) attach to Rh antigens on RBCs.
- Immune-mediated destruction of RBCs leads to hemolysis, anemia, and increased bilirubin production.
- Transfusion of Rh-positive blood to Rh-negative recipient
- Maternal exposure to fetal Rh antigens, either antepartum or intrapartum
- Most commonly seen in the Rh-positive fetus or infant of an Rh-negative mother

#### *Genetics*

- Complex autosomal inheritance of polypeptide Rh antigens; three genetic loci with closely related genes carry an assortment of alleles: Dd, Cc, and Ee.
- Individuals who express the D antigen (also called *Rho* or *Rho[D]*) are considered Rh-positive. Individuals lacking the D antigen are Rh-negative.

- Variant D alleles (weak D and partial D) are heterogenous, altered forms of the D antigen. Some D variants are at risk of formation of anti-D antibodies, whereas others are not. With current blood typing procedures, certain D variants likely to produce alloimmunization are typed as D-negative, although this does not include all genetic subtypes at risk of isoimmunization (1).
- Another variant D antigen, DEL, has been identified in some individuals (predominantly Asians) who are classified as Rh-negative by the usual assays. Although testing Rh-negative, these individuals are not likely to be sensitized by exposure to Rh-D antigens through pregnancy or transfusion and should be considered clinically Rh-positive (2).
- Antibodies may be produced to C, c, D, E, or e in individuals lacking the specific antigen; only D is strongly immunogenic (3).
- Isoimmunization to Rh antigens in susceptible individuals is acquired, not inherited.

## **RISK FACTORS**

- ~15% of the white population and smaller fractions of other races are Rh-negative and susceptible to sensitization (4).
- Any Rh-positive pregnancy in an Rh-negative woman can result in sensitization.
- Weak D and partial D women are a heterogenous group. Although previously reported to be Rh positive and treated as such, alloimmunization has been reported and can result in HDFN or fatal hydrops fetalis (5).
- Native risk of isoimmunization after Rh-positive pregnancy had been estimated at ~15% but seems to be decreasing.
- The risk of isoimmunization antepartum is only 1-2%.
- The risk of isoimmunization is 1-2% after spontaneous abortion and 4-5% after induced abortion (6).
- Use of Rho(D) immunoglobulin prophylaxis has reduced incidence of isoimmunization to <1% of susceptible pregnancies (7)[A].

## **GENERAL PREVENTION**

- Blood typing (ABO and Rh) on all pregnant women and prior to blood transfusions
- Antibody screening early in pregnancy
- Rh immunoglobulin prevents only sensitization to the D antigen.
- For prophylaxis, Rho(D) immunoglobulin (RhIG, Rho-GAM, HyperRHO, Rhophylac) given to unsensitized, Rh-negative women after the following:

- Spontaneous abortion
  - Induced abortion
  - Ectopic pregnancy
  - Antepartum hemorrhage
  - Trauma to abdomen
  - Amniocentesis
  - Chorionic villus sampling
  - Within 72 hours of delivery of an Rh-positive infant
  - Given routinely at 28 weeks gestation
- Prophylaxis is to prevent sensitization affecting a subsequent pregnancy and has little effect on the current pregnancy.
  - Dose for prophylaxis
    - 50- $\mu$ g dose for events up to 12 weeks gestation
    - 300- $\mu$ g dose for events after 12 weeks gestation
    - Higher doses may be required in the event of a large fetal-maternal hemorrhage (>30 mL of whole blood).

## COMMONLY ASSOCIATED CONDITIONS

- Hemolytic disease of newborn
- Hydrops fetalis
- Neonatal jaundice
- Kernicterus
- See Erythroblastosis Fetalis topic.

## DIAGNOSIS

### PHYSICAL EXAM

- Jaundice of newborn
- Kernicterus
- Fetal hydrops or fetal death in utero if severe (see Erythroblastosis Fetalis topic)

## *DIFFERENTIAL DIAGNOSIS*

- ABO incompatibility
- Other blood group (non-Rh) isoimmunization
- Nonimmune fetal hydrops
- Hereditary spherocytosis
- RBC enzyme defects

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Positive indirect Coombs test (antibody screen) during pregnancy
- Paternal blood type
- Kleihauer-Betke (fetal hemoglobin acid elution, Hb F slide elution) test to quantify an acute fetal-maternal bleed
- Flow cytometry using antibody to hemoglobin F is emerging as an alternative to the Kleihauer-Betke test to detect or quantify fetal-maternal bleed (8).
- Congenital or fetal anemia
- Blood type, direct Coombs test in newborn
- Cell-free fetal DNA (Cff DNA) test (see *ÒClinical PearlsÓ*)

### *Follow-Up Tests & Special Considerations*

Prior administration of Rho(D) may lead to weakly (false-) positive indirect Coombs test in mother and direct Coombs test in infant.

## **TREATMENT**

### *GENERAL MEASURES*

- Depending on severity of involvement, treatment of fetus may include the following:
  - Intrauterine transfusion (9)[C]
  - Early delivery
- Treatment of newborn may include the following:

- Exchange transfusion
  - Transfusion after delivery
  - Phototherapy
- Inconclusive evidence on efficacy of IVIG to reduce need for exchange transfusion (10)[A]

## *ISSUES FOR REFERRAL*

Because of the specialized, somewhat hazardous treatment measures involved, pregnancies in Rh-sensitized women are usually managed at tertiary-care facilities with maternal fetal medicine specialists.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Initial monitoring of the newborn is inpatient or in special care nursery if treatment interventions are needed.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- In most cases, outpatient ambulatory management is appropriate during the antepartum period.
- Antibody titer measured at 20 weeks and every 4 weeks thereafter during pregnancy; a titer of  $\geq 1:16$  indicates the need for further testing (5).
- If the patient had a previously affected infant, an Rh-positive fetus in the current pregnancy should be considered at risk regardless of antibody titers (11).
  - Fetal heart rate testing/US to assess fetal status
  - Doppler US measurement of cerebral blood flow is now a suitable alternative to invasive tests (amniocentesis, cordocentesis) for diagnosing fetal anemia (11).
  - Umbilical blood sampling (cordocentesis) for fetal blood type, hematocrit, reticulocyte count, and presence of erythroblasts (5)
  - Amniocentesis for amniotic fluid bilirubin levels (5)

- Amniocentesis for fetal lung maturity if early delivery is a treatment option (5).

## PROGNOSIS

- With appropriate monitoring and treatment, infants born of severely affected pregnancies have a survival rate of >80% (11).
- Even with severe disease, the neurologic outcome of survivors is generally good (8)[C].
- Fetuses with hydrops have a higher mortality rate and higher risk of neurologic impairment (8) [C].
- Disease is likely to be more severe in affected subsequent pregnancies.

## COMPLICATIONS

- Pregnancy loss from umbilical blood sampling
- Pregnancy loss from intrauterine transfusion
- Fetal distress requiring emergent delivery (12)

## ICD10

- P55.0 Rh isoimmunization of newborn
- O36.0990 Maternal care for other rhesus isoimmunization, unspecified trimester, not applicable or unspecified
- T80.40XA Rh incompat react due to transf of bld/bld prod, unsp, init

## Clinical Pearls

**&NA;**

- If paternity is certain, determining that the father does not carry the Rh(D) blood group antigen eliminates the need to give RhIG prophylaxis during pregnancy or the need for special fetal surveillance if the mother is already sensitized.
- Cell-free fetal DNA (Cff DNA) testing has evolved as the standard practice in many European countries; it is available in the United States but is not a widely covered benefit. It allows detection of fetal Rh genotype with accuracy of 97.1%, sensitivity of 97.2%, and specificity of 96.8% (11).
- Cff DNA testing with selective administration of Rh immunoglobulin when the fetus tests Rh positive has been shown to be as effective at preventing new Rh sensitization when compared to routine administration of Rh-immunoglobulin to all Rh-negative women. Such an approach avoids unnecessary use of Rh immunoglobulin (13). Currently, routine administration of Rh immune globulin is more cost effective than use of Cff DNA testing in the United States (14).
- The dose of RhIG for prophylaxis is affected by gestational age. The fetal blood volume is only a few milliliters at 12 weeks gestation. Therefore, a 50-*mcg* dose of RhIG may be used for threatened, spontaneous, or induced abortions up to 12 weeks gestation, instead of the standard 300-*mcg* dose.

# Rhabdomyolysis

Caroline Tschibelu, MD

Chirag N. Shah, MD

## BASICS

### DESCRIPTION

- Breakdown of skeletal muscle cells and release of intracellular contents into the circulation
- Rhabdomyolysis typically manifests with muscle aches, pains and weakness, and reddish brown (tea-colored) urine, but up to 50% of patients are asymptomatic.

### EPIDEMIOLOGY

#### *Incidence*

Annually in the United States: 26,000 hospitalized cases

### ETIOLOGY AND PATHOPHYSIOLOGY

- Direct muscle trauma (most common cause)
  - Crush injuries
  - Extended periods of muscle pressure (during surgery, unconscious from alcohol ingestion)
  - Burns, electrocution, lightning strike
- Muscle exertion
  - Intense and/or prolonged physical exercise (marathon runners, athletes, contact sports)
  - Seizures
  - Delirium tremens
- Drugs and toxins
  - Alcohol
  - Cocaine (most common recreational drug), methamphetamine, phencyclidine
  - Antipsychotics (due to neuroleptic malignant syndrome, malignant hyperthermia, and severe

dystonia)

- Zidovudine
  - Antimalarials
  - Heroin
  - HMG-CoA reductase inhibitors (statins) (risk <0.01%), higher with high dose and in combination with fibrates
  - Fibrates
  - Colchicine
  - Corticosteroids
  - Carbon monoxide
  - Snake envenomation
  - Bath salts (1)[B]
  - Synthetic cannabinoid: Abuse of synthetic marijuana has been associated with severe rhabdomyolysis (2)[C].
- Muscle ischemia
    - Thrombosis, embolism, sickle cell disease
    - Compartment syndrome
    - Tourniquets
  - Infections
    - Viral: influenza A and B, coxsackievirus, HIV, varicella
    - Bacterial: *Streptococcus* or *Staphylococcus* sepsis, gas gangrene, necrotizing fasciitis, *Salmonella*, *Legionella*
    - Malaria
  - Hypothermia
  - Hyperthermia
  - Autoimmune and genetic disorders
    - Polymyositis, dermatomyositis
    - Muscular dystrophies
    - Disorders of lipid metabolism (e.g., carnitine palmitoyltransferase deficiency)

- Disorders of carbohydrate metabolism (i.e., phosphofructokinase deficiency, phosphoglycerate mutase, myophosphorylase deficiency, aka McArdle disease/deficiency)
- Glycogen storage diseases (e.g., phosphorylase B kinase deficiency) and others (e.g., lactate dehydrogenase A deficiency)
- Metabolic and endocrinologic:
  - Hypothyroidism or thyrotoxicosis
  - Electrolyte imbalances (e.g., hyponatremia, hypernatremia, hypokalemia, hypocalcemia, hypophosphatemia)
  - Diabetic ketoacidosis
  - Hyperosmolar state

## Genetics

- Hereditary causes of rhabdomyolysis are rare but should be suspected for children, patients with recurrent attacks, or patients who have attacks after minimal exertion, mild illness, or starvation.
- The main inherited disorders are described earlier in *Etiology and Pathophysiology*.

## RISK FACTORS

See *Etiology and Pathophysiology*.

## GENERAL PREVENTION

- Avoid excessive exertional muscle injury. Preventing hypovolemia is important to prevent renal hypoperfusion, acidemia, and subsequent renal failure.
- Avoid precipitating drugs, metabolic and electrolyte abnormalities.

## DIAGNOSIS

### HISTORY

- Crush injury: direct trauma, prolonged compression/immobility. Causes include motor vehicle accidents (MVA) and entrapment in collapsed buildings. The elderly are more susceptible to crush injury due to immobility and falls. Rhabdomyolysis usually occurs after 1 hour of immobilization, but cases reported with compression lasting <20 minutes.
- Possible history of overexertion or use of drug/toxin (e.g., cocaine,

amphetamine, statins)

- Patient may complain of muscle aches, cramps, or fatigue.
- Agitation while patients are in restraints

## *PHYSICAL EXAM*

- May have obvious muscle tenderness/injury and swelling on exam, or muscle exam may be completely normal
- Tea-colored urine is indicative of myoglobinuria.
- Decreased urine output may indicate renal failure.

## *DIFFERENTIAL DIAGNOSIS*

- For acute renal failure with rhabdomyolysis: Any disease that causes acute tubular necrosis may be confused with rhabdomyolysis.
- Renal pigment injury from hemoglobin resembles pigment injury from myoglobin.

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Creatine kinase (CK) is the most important diagnostic enzyme: Elevated  $>5$  times the upper limit of normal or  $>1,000$  U/L. CK levels  $>5,000$  U/L are causally related to acute renal failure (ARF) (3)[A] and should prompt aggressive fluid resuscitation.
- CK levels peak at  $\pm 24$  hours and return to normal after 3 to 5 days, making it a more sensitive marker than myoglobin. CK is also a cheaper and an easier surrogate than myoglobin. Myoglobin is the enzyme responsible for kidney failure (3)[A].
- Serum myoglobin levels peak within a few hours and return to normal after  $\pm 24$  hours, as it is cleared quickly from the circulation. Urine/serum myoglobin levels may be useful markers early on, but normal levels do not rule out rhabdomyolysis because of its rapid clearance.
- Urinalysis: Dipstick test positive for blood without erythrocytes in sediment is suggestive of injury from either hemoglobin or myoglobin. However, rhabdomyolysis often presents with hematuria, which is a limitation to using dipstick due to false-positive results.
- Marked elevations of potassium from the muscle injury sometimes are compounded by ARF.
- Initial hypocalcemia: Calcium enters the injured muscle cells and precipitates as calcium phosphate, leading to calcification of ischemic muscle cells. Only correct initial hypocalcemia if patient is symptomatic or has ECG changes; it will self-resolve during the renal recovery phase.

Hypercalcemia during renal recovery phase: Unique to rhabdomyolysis-induced ARF for 20-30% of patients (3)[A]. As renal function improves, there is mobilization of the precipitated calcium, increase in calcitriol, and hyperphosphatemia resolves.

- Extreme hyperuricemia may be present and can cause acute uric acid nephropathy in the setting of rhabdomyolysis.
- Elevations in BUN and creatinine are indicative of acute renal failure.
- Reversible hepatic dysfunction can occur. However, elevations in alanine aminotransferase (ALT), aspartate aminotransferase (AST), and lactic dehydrogenase may be due to muscle injury and may not indicate any hepatic injury.
- Disseminated intravascular coagulation (DIC) can occur, with increase in coagulation times, fibrin degradation products, and D-dimer; decreases in platelets and fibrinogen.
- Place patient on a 12-lead ECG if rhabdomyolysis is suspected because hyperkalemia can induce fatal arrhythmias.

### *Follow-Up Tests & Special Considerations*

- Delayed renal failure/electrolyte abnormalities despite normal initial levels
- Ongoing muscle injury is manifested by rising creatine phosphokinase (CPK).
- Any renal imaging is similar to other evaluations of acute renal failure.

### *Diagnostic Procedures/Other*

Muscle compartment pressures if compartment syndrome is suspected

### *Test Interpretation*

- Muscle necrosis
- Myoglobin-related renal injury may resemble acute tubular necrosis from other causes.

## **TREATMENT**

### *GENERAL MEASURES*

- Aggressive hydration is often necessary. With severe muscle trauma (crush injuries), up to 12 L of fluid may be sequestered in the muscles, leading to intravascular volume depletion and explaining the low urine output despite fluid resuscitation, which increase the risk for renal failure.

- Monitor CK levels to ensure that rhabdomyolysis has ended.
- Monitor renal function and electrolytes.
- Continuous monitoring of potassium levels to prevent hyperkalemic arrhythmias and potential hypokalemia and arrhythmias.
- If DIC/hepatic dysfunction occurs, patients will need treatment and monitoring appropriate to these conditions.

## MEDICATION

### *First Line*

- When rhabdomyolysis is identified, appropriate intervention may prevent renal failure.
- Aggressive fluid resuscitation is the most important intervention: normal saline (NS) and 5% glucose solution with a target urine output of 200 mL/hr. Alternating NS and 5% glucose is recommended to prevent volume overload. Infusion rate should be 500 mL/hr (4)[C].
- Alkalinization of the urine is thought to decrease myoglobin-induced nephrotoxicity in the tubules (sodium bicarbonate to increase urine pH >6.5):
  - Use is controversial without strong evidence of efficacy.
  - Side effects include worsening hypocalcemia.
  - Sodium bicarbonate may be of use in patients with very high CK levels, an acidotic state, or coexisting hyperkalemia.
  - Place 150 mEq (3 ampules) NaHCO<sub>3</sub> in 1 L of D5W and infuse at 200 mL/hr.

### *Second Line*

- IV mannitol as a bolus if urine output remains low, 1 to 2 g/kg, not to exceed 200 g in 24 hours and cumulative dose up to 800 g. It is used to prevent ARF (5)[C]. Plasma osmolality should be closely monitored and stopped if diuresis is not adequate (>20 mL/hr).
  - Increases prostaglandins production leading to renal vasodilation and diuresis, making the kidneys less susceptible to myoglobin injury. Also an osmotic agent, filtered but not reabsorbed by the tubules, it increases sodium delivery and diuresis. This may remove necrotic cell debris and fluids trapped in damaged muscle cells preventing rise in compartment pressure and compartment syndrome.
  - Use of mannitol is controversial in this setting because no good evidence indicates that it improves outcomes more than aggressive IV hydration. It is a free-radical scavenger and has renal protective effects when used early, before tubular occlusion.

- Consider adding furosemide to force diuresis if necessary (40 to 120 mg/day).
- Diuresis should not be used in anuric renal failure. Customize the regimen for elderly and patients with heart disease.
- Hyperkalemia can result from massive release of intracellular potassium stores or ARF. Severe hyperkalemia may be life-threatening. Treatment is warranted when ECG changes are present (tall, thin T waves; PR prolongation; QRS widening; P wave flattening).
- Treatments aiming at resolving hyperkalemia:
  - Calcium gluconate: to stabilize the cardiac membrane. IV 1 to 2 ampules (0.5 mL 10% Calcium gluconate = 4 mg elemental calcium; give 4 mg/kg/hr for 4 hours)
  - If acidosis is present: 1 to 2 ampules (2 to 3 mL/kg) sodium bicarbonate IV. Remember that sodium bicarbonate administration worsens hypocalcemia.
  - If tolerated: Oral sodium polystyrene sulfonate (Kayexalate) as much as 20 g (1 g/kg) can be given via enema.
  - Insulin and albuterol will transiently drive potassium into the cells. Administration of glucose can prevent the hypoglycemic effects of insulin.
  - Precautions: See Etiology and Pathophysiology, especially drug combinations. Continuous monitoring of potassium levels to prevent overcorrecting with potential hypokalemia and arrhythmias.
  - Indications for dialysis include resistant and symptomatic hyperkalemia (ECG), oliguria (<0.5 mL/kg over 12-hour period), anuria, volume overload, or persistent acidosis (pH <7.1).

## **ISSUES FOR REFERRAL**

- Usually managed as an inpatient
- Diagnosis of muscle entrapment/compartiment syndromes may require surgical intervention (fasciotomy) to stop rhabdomyolysis.
- Early escharotomy for compartment syndrome related to burn
- Renal dialysis may be indicated in ARF.

## **ADDITIONAL THERAPIES**

During the oliguric phase, symptomatic hypocalcemia is possible but rare and may benefit from IV calcium gluconate.

## **SURGERY/OTHER PROCEDURES**

For muscle entrapment/compartment syndrome

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Patients with significant elevations of CK should be admitted for IV hydration and serial laboratory monitoring.
- Usually required for symptomatic patients or other complications

### *IV Fluids*

Volume expansion with normal saline to increase urine output to at least 150 mL/hr

### *Nursing*

Monitoring of vital signs and urine output

### *Discharge Criteria*

CK usually peaks 24 to 36 hours after muscle injury, so monitoring should confirm that the CK is trending down. Renal function should be stable/improving. Electrolytes should be normal. Patients with mild CK elevation, trending down, and normal renal function may be discharged after observation phase.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Outpatient assessment within a few days to recheck CPK, electrolytes, and renal function

### *Patient Monitoring*

- Contingent on disease: essential for metabolic myopathies
- Myotoxic drugs should be discontinued/monitored closely.

### *DIET*

- With renal failure, restrict protein intake to lower BUN level.
- Limit potassium intake.
- With anuria, essential to restrict volume intake

## PROGNOSIS

Contingent on primary cause of rhabdomyolysis and on recovery from ARF without complications

## COMPLICATIONS

- Death, especially from hyperkalemia/renal failure
- With dialysis and supportive care, the prognosis is very good.

Algorithm: Acute Kidney Injury (Acute Renal Failure)

## Codes

**&NA;**

### ICD10

- M62.82 Rhabdomyolysis
- T79.6XXA Traumatic ischemia of muscle, initial encounter
- T79.6XXD Traumatic ischemia of muscle, subsequent encounter

## Clinical Pearls

**&NA;**

- Acute CPK elevation into the thousands (often tens of thousands) is necessary before one sees myoglobinuric renal failure.
- The cornerstone of treatment of rhabdomyolysis is aggressive fluid administration.
- Frequent monitoring of potassium, calcium, and creatinine is necessary in the acute period.

# Rhabdomyosarcoma

Olusola Fasusi, MD

E. James Kruse, DO

## BASICS

### DESCRIPTION

- Rhabdomyosarcoma (RMS) is the most common soft tissue sarcoma in children <20 years of age. (It is exceedingly rare in adults, representing 3% of all soft tissue sarcomas.)
  - 50% occur in the 1st decade of life.
- Overall, it is an uncommon malignancy that arises from myoblasts.
- Common anatomic sites
  - Head and neck (most common primary site in children)
  - Genitourinary
  - Musculoskeletal (Extremities are the most common primary sites in adults.)
- Subtypes
  - Alveolar (ARMS): 23% of cases
    - More common in the trunk and extremities; clinically more aggressive
  - Embryonal (ERMS): early onset; 57% of cases (most common subtype in children)
    - More likely to occur in the head, neck, and genitourinary areas
      - Classic: comprises 50% of cases
      - Botryoid: Sarcoma botryoids is typically seen in girls <4 years of age, 6% of cases.
      - Spindle cell: 3% of cases pleomorphic: usually occurs in adults, 1% of cases
- Sarcoma (not otherwise specified): comprises 11% of all cases of RMS (most common subtype in adults, reflects inability for pathologists to characterize tumor)
- Undifferentiated: comprises 8% of all cases of RMS
- Associated term(s): soft tissue sarcoma

Stage	Site	T	Tumor diameter	N	M
1	Orbit; head and neck (excluding parameningeal); genitourinary nonbladder and nonprostate; biliary tract	T1 or T2	a or b	N0 or N1 or NX	M0
2	Bladder or prostate; extremity; cranial parameningeal; other (includes trunk, retroperitoneum, etc.)	T1 or T2	a	N0 or NX	M0
3	Bladder or prostate; extremity; cranial parameningeal; other (includes trunk, retroperitoneum, etc.)	T1 or T2	a	N1	M0
			0 or N1 or NX	M0	
4	All sites	T1 or T2	a or b	N0 or N1	M1

Note: a,  $\leq 5$  cm in diameter; b,  $>5$  cm in diameter; T1, confined to site of origin; T2, extension and/or fixation to surrounding tissue; N0, regional nodes not clinically involved; N1, regional nodes clinically involved by neoplasm; Nx, clinical status of regional nodes unknown; M0, no distant metastasis present; M1, metastasis present.

## EPIDEMIOLOGY

### *Incidence*

- 4.5 cases of RMS per 1 million patients <20 years old per year – 50% occur within 1st decade of life.
- In adults, RMS represents 3% of all soft tissue sarcomas in adults.

### *Prevalence*

- RMS comprises 3% of all childhood cancers.
- Predominant sex: male > female (1.37:1)

## Genetics

- Alveolar: *PAX3-FOXO1* or *PAX7-FOXO1* fusion genes as a result of t(2;13) and t(1;13), respectively; found in 75% of ARMS
- Embryonal: Loss of alleles on chromosome 11 may be seen.

## RISK FACTORS

Smoking, advanced maternal age, in utero x-ray exposure, maternal recreational drug use, and history of stillbirths

## COMMONLY ASSOCIATED CONDITIONS

- Neurofibromatosis (NF1) 1: 20-fold increased risk of RMS in patients with NF1
- Li-Fraumeni syndrome: p53 mutations predispose to multiple tumors, including RMS.

## DIAGNOSIS

### HISTORY

- Presents as a progressive painless mass of the head and neck, genitourinary tissue, trunk, or extremities
- RMS of genitourinary tissue may present as vaginal bleeding in females.
- Other symptoms may be noted due to mass effect of the primary or metastatic lesions.
- Family history of genetic syndromes (i.e., NF1, Li-Fraumeni syndrome)

## PHYSICAL EXAM

- Painless, enlarging mass
- Polypoid mass protruding from vagina (botryoid)
- Exophthalmos and chemosis (orbital involvement)
- Abdominal pain
- Compression symptoms (i.e., seizures, visual field defects, nerve palsy, headaches)

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Ultrasound: used for differentiation of cystic versus solid mass

- MRI/CT: used to evaluate tumor
- Staging tests: chest x-ray, CT thorax, fluorodeoxyglucose (FDG)-PET
  - Most common site of metastasis is lung; evaluated by CT
  - FDG-PET scans may be useful to detect lymph node or distant metastases; not readily evident on CT or MRI scans

## *Diagnostic Procedures/Other*

- Core needle biopsy, incisional biopsy, or excisional biopsy (based on size of mass)
  - The presence of rhabdomyoblast indicates the diagnosis.
- Immunohistochemical markers
  - Myogenin: commonly expressed in ARMS
  - Desmin: associated with multiple subtypes of RMS
- Pathology
  - Alveolar: rhabdomyoblasts arranged in what grossly appears to mimic pulmonary alveoli
  - Embryonal
  - Classic: rhabdomyoblasts configured in sheets without alveolar pattern
  - Botryoid: "grape-like" appearance of rhabdomyoblasts with notable clustering in the subepithelium forming the cambium layer
  - Spindle cell: rhabdomyoblasts with a spindle-like appearance
- Undifferentiated: rhabdomyoblast arrangement that cannot be classified as any other subtype
- Staging
  - Based on site, size, regional nodal involvement, and distance spread
  - See table.

## **TREATMENT**

The three tenets of treatment for adults and children are composed of surgical resection, radiation therapy, and chemotherapy. Patients should be referred to a multidisciplinary treatment team with expertise in oncology for definitive treatment.

## ***SURGERY/OTHER PROCEDURES***

- Wide local resection of tumor. If possible, resect metastasis as well.
- However, wide resection may not be feasible in cases where grossly impaired functionality results.
  - All children receive chemotherapy (1)[B].
  - In North America, the three-drug combination of vincristine, dactinomycin, and cyclophosphamide (VAC) is the standard regimen:
    - Vincristine
      - Adverse reactions: alopecia, constipation, peripheral neuropathy
    - Actinomycin-D
      - Adverse reactions: pancytopenia, hepatotoxicity
    - Cyclophosphamide
      - Adverse reactions: hemorrhagic cystitis (mesna for prophylaxis), sterility, transitional cell carcinoma
- In addition, ifosfamide, topotecan, doxorubicin, etoposide, and irinotecan may also be used.
- Duration of chemotherapy depends on risk stratification and ranges from 6 to 12 months.
- Chemotherapy has been less commonly used in adults, who generally undergo treatment with resection and radiation therapy.
- Radiotherapy is currently used for those whose tumor cannot be completely resected.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Patients should follow up with their multidisciplinary treatment team. Long-term follow-up is necessary for detection of recurrence, metastatic disease, and development of secondary malignancies. Follow-up is composed of physical exam, chest x-ray, and imaging of the primary tumor site every 3 to 6 months for the first 3 years.

### ***PROGNOSIS***

- RMS (all cases): 62% 5-year survival

- ARMS: 48% 5-year survival
- ERMS: 73% 5-year survival
- Prognosis in adults is worse; it is unclear whether this is related to subtype of tumor or lack of clear guidelines for adults; this is a rare presentation in adults.

## COMPLICATIONS

- Recurrence
- Secondary neoplasm
- Growth abnormalities
- Treatment side effects

## Codes

&NA;

### ICD10

- C49.9 Malignant neoplasm of connective and soft tissue, unsp
- C49.0 Malignant neoplasm of connective and soft tissue of head, face and neck
- C49.5 Malignant neoplasm of connective and soft tissue of pelvis

### Clinical Pearls

&NA;

- RMS is the most common soft tissue sarcoma in children.
- They can arise at any site and in any tissue except bone.
- All persistent soft tissue masses should be evaluated with imaging (ultrasound to rule out cystic vs. solid, then MRI/CT).
- Fine-needle aspiration may be helpful but core needle versus incisional/excisional biopsy for confirmation.

# Rheumatic Fever

Jonathan Schimmel, MD

Achyut B. Kamat, MD

## BASICS

### DESCRIPTION

- Acute rheumatic fever (ARF) is a delayed inflammatory sequela of group A *Streptococcus* (GAS) tonsillopharyngitis that affects multiple organ systems.
- Can lead to rheumatic heart disease (RHD)
- Recurrence in adults and children is common if antibiotic prophylaxis is withheld.
- Systems affected: cardiovascular, nervous, hematologic/lymphatic/immunologic, skin/exocrine, musculoskeletal

### *Pediatric Considerations*

Can affect any age but most common ages 5 to 15 years

### EPIDEMIOLOGY

- ARF and RHD are now largely restricted to developing countries and some poor populations of wealthy countries.
- Male = female, but females more likely to develop chorea.
- Can occur as an epidemic

### *Incidence*

- Worldwide, incidence (new cases) has been declining for decades, attributed to increasing antibiotic use and improved living conditions. Most new cases are in developing countries.
- In early studies, ARF developed in 3% of children with untreated GAS pharyngitis.
- Incidence of ARF in the United States in the 1960s was 13.3/100,000 and is currently <1/100,000.
- 95% of cases currently occur in developing countries.

## Prevalence

Worldwide, more than 15 million people have RHD, and prevalence has been rising due to improved medical care and longer survival (despite decreasing incidence of ARF).

## ETIOLOGY AND PATHOPHYSIOLOGY

- Preceded by tonsillopharyngitis of GAS, also known as *Streptococcus pyogenes*, a gram-positive organism
- Molecular mimicry: Antibodies against M protein on GAS cross-reacts with cardiac and vessel endothelial proteins, leading to an inflammatory cascade.

## Genetics

- Susceptibility is associated with certain genetic polymorphisms, including toll-like receptors, cytokines, and human leukocyte antigen genes. Not fully understood
- Increased susceptibility in certain populations, including Australian aborigines, New Zealand Maori, and Pacific Islanders

## RISK FACTORS

Genetic susceptibility and possible increased risk with iron deficiency or low serum albumin.

## GENERAL PREVENTION

- Primary prevention: Antibiotics are effective at reducing incidence of ARF after known or suspected GAS pharyngitis. Number needed to treat is 100 (1)
- Secondary prevention: long-term antibiotic prophylaxis to prevent recurrence

## DIAGNOSIS

- Requires laboratory evidence of preceding GAS infection (see Initial Tests (lab, imaging)).
- Revised Jones criteria
- Initial ARF: 2 major OR 1 major + 2 minor
- Recurrent ARF: 2 major OR 1 major + 2 minor OR 3 minor

### Major Criteria

- Carditis/valvulitis

### Minor Criteria

- Low-risk: fever  $\geq 38.5^{\circ}\text{C}$
- Mod-high risk: fever  $\geq 38^{\circ}\text{C}$

- Low-risk: polyarthrititis
  - Mod-high risk: mono/polyarthrititis
  - Sydenham chorea
  - Erythema marginatum
  - Subcutaneous nodules
  - Low-risk: polyarthralgia
  - Mod-high risk: monoarthralgia
  - ↑PR interval
  - CRP  $\geq 3$  mg/dL, and/or
  - Low-risk: ESR  $\geq 60$  mm/hr
  - Mod-high risk: ESR  $\geq 30$  mm/hr
- The revised criteria distinguish between patients with low-risk versus moderate-high risk of having ARF. Patients can be considered low-risk if they are from and among a low incidence group (2)[C].

## HISTORY

- ARF presents 1 to 4 weeks following GAS tonsillopharyngitis.
- Polyarthrititis is often first, affecting the knees, ankles, elbows, and wrists. Each resolves in days, thus seems to “migrate.” Usually self-limited <1 month. Mod-high risk patients may develop monoarthrititis. Use of NSAID or aspirin may mask the arthritis.
- Fever
- Erythema marginatum rash
- Pancarditis or valvulitis (50-70%) can be subclinical (asymptomatic without auscultatory findings) or clinically apparent (symptomatic or auscultatory findings).
- Sydenham chorea (clinical diagnosis, in 10-30%)
  - 1 to 6 months after infection, so lab evidence of preceding infection may be absent.
  - More common in 5 to 15 years old, more common in females
  - Improves or ceases during sleep.
  - Psychiatric symptoms may have onset prior to chorea, with emotional lability and obsessive-compulsive symptoms.
  - Usually self-resolves over several months and can relapse

## PHYSICAL EXAM

- Neuro: Sydenham chorea: Involuntary movements may be general or unilateral and may involve the face. ÒMilkmaid gripÓ is intermittent hypotonia appreciated on test of grip

strength.

- Cardiac: pericardial friction rub, blowing holosystolic murmur, rarely diastolic, or new or changing murmur; rarely evidence of heart failure
- Skin
  - Subcutaneous nodules (<10%): firm, painless, up to 2 cm, over bony surfaces or tendons, usually extensor surfaces. More common in severe ARF, persists up to several weeks
  - Erythema marginatum (5-13%): nonpruritic, blanching, evanescent, pale pink macular transitions to central clearing, found on trunk and occasionally limbs, accentuated by warming the skin

## *DIFFERENTIAL DIAGNOSIS*

- Systemic lupus erythematosus
- Poststreptococcal reactive arthritis
- Juvenile rheumatoid arthritis
- Infectious arthritis
- Viral myocarditis
- Innocent cardiac murmur
- Tourette syndrome
- Kawasaki syndrome
- Pediatric autoimmune neuropsychiatric disorders associated with streptococcal infections (PANDAS)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Bacteriologic/serologic evidence of GAS infection (2)[B]:
  - Rapid streptococcal antigen test with high pretest probability
  - Throat culture (sensitivity 25% by time of ARF)
  - Elevated or rising antistreptolysin O (ASO) titer; peaks  $\div$  1 month postinfection.
- If ASO negative, check anti-DNAse B (peaks  $\div$  2.5 months, remains elevated up to 9 months), streptokinase, and antihyaluronidase (3).
- Bacteriologic/serologic evidence may be negative in chorea or chronic indolent rheumatic

carditis.

- ESR and CRP are acute-phase reactants that almost always increase in ARF.
- CBC with differential: leukocytosis, possible normocytic anemia
- Complement levels normal (do not need to check)
- ECG: PR prolongation, AV block, signs of pericarditis
- Arthrocentesis of affected joints shows sterile inflammatory fluid with 10 to 100,000 WBC/mm<sup>3</sup>.
- Chest x-ray: may have cardiomegaly from myocarditis
- Echocardiogram: Assess chamber size and function, pericardial effusion, and valve disease.
- All cases of confirmed or suspected ARF should have an echocardiogram (2)[B], due to the 18% prevalence of subclinical carditis.
- Antimyosin scintigraphy can detect carditis (nonspecific).

---

P.925

### *Follow-Up Tests & Special Considerations*

- ESR and CRP are useful to monitor rebound inflammation.
- Repeat echocardiograms to monitor evolution of carditis, even if not initially present (2)[C].
- Household contacts should be screened with throat culture even if asymptomatic and treated with antibiotics if positive.

### *Test Interpretation*

Prior treatment with aspirin or steroids may lead to falsely normal lab results.

## **TREATMENT**

### *GENERAL MEASURES*

- Antibiotic
- Anti-inflammatory agent (aspirin or naproxen)
- Manage cardiac manifestations as needed in addition to standard ARF treatment (e.g. dysrhythmia, pericarditis, myocarditis, valvular disease, or heart failure).

### *MEDICATION*

## *First Line*

- Eradication: Treat initially as if active GAS infection, then begin prophylaxis.
- If no penicillin allergy
  - Penicillin VK PO BID for 10 days, or benzathine penicillin G IM for 1, or amoxicillin PO for 10 days (preferred in children) (4)[A]
- If penicillin allergy
  - Cephalosporin 1st generation PO for 10 days (4)[A], azithromycin PO for 5 days, or clindamycin PO for 10 days, or clarithromycin PO for 10 days (4)[B]
- If there is heart failure, AV block third degree, or other severe manifestations of carditis, appropriate traditional management should be initiated.
- Aspirin high-dose is effective for treatment of arthritis and fever (5)[B], but has not been shown to reduce or improve cardiac manifestations (6)[B]. High-dose aspirin for prolonged periods risks salicylate toxicity and if used, consider following salicylate levels.
- If severe carditis is present, consider prednisone, although not shown to prevent or reduce cardiac manifestations (6)[B].
- Chorea generally self-resolves and does not require treatment, but if symptoms are severe, can use valproic acid, carbamazepine, or an antipsychotic if still resistant (3)[B]. If symptoms persist, consider prednisone, which unlike cardiac disease has been shown effective for Sydenham chorea (3)[B].

## *Second Line*

- If penicillin allergy is present, erythromycin is preferred by the New Zealand guidelines, but not by the Infectious Diseases Society of America.
- Naproxen is a reasonable alternative to aspirin (see "Pediatric Considerations").

## **ISSUES FOR REFERRAL**

A cardiologist should be involved in management of ARF.

## **SURGERY/OTHER PROCEDURES**

Valve stenosis is a late sequela that can result from fibrosis and calcification; it may require surgical correction (valve repair preferred over replacement) (7).

## **INPATIENT CONSIDERATIONS**

## *Admission Criteria/Initial Stabilization*

- Initial hospitalization may be helpful for diagnosis and to ensure stability.
- Heart failure requires prompt hospitalization.

## *IV Fluids*

Only if signs of dehydration or to augment preload; use caution if heart failure present.

## *Nursing*

Consider bedrest if severe symptoms, with gradual return to ambulation as tolerated (8)[C].

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- ARF patients should be on a prophylactic antibiotic throughout childhood until age 21 years and possibly indefinitely depending on cardiac damage because recurrence can worsen prognosis (9)[C].
  - First-line prophylaxis is **long-acting** benzathine penicillin G monthly IM injections (9)[A].
  - Penicillin V PO 250 mg BID is an alternative but has risk of nonadherence (9)[B].
  - If penicillin allergy, treat with sulfadiazine (9)[B].
  - If penicillin and sulfa drug allergy, treat with azithromycin (9)[C].
- If diagnostic uncertainty exists, consider 1 year of secondary antibiotic prophylaxis followed by reassessment and echocardiogram (2)[C].
- Routine antibiotic prophylaxis for dental procedures is no longer recommended by the American Heart Association for patients with RHD (7).
- Have low threshold to test and treat episodes of acute tonsillopharyngitis.

## *Patient Monitoring*

Initially weekly, then every 6 months

## *Pediatric Considerations*

- Use aspirin with caution in children given the risk of Reye syndrome.
- Naproxen (10 to 20 mg/kg/day) has been found noninferior to aspirin with fewer risks in ARF, in a small study (5)[B].

## *Pregnancy Considerations*

May exacerbate valve disease, particularly mitral stenosis. Refer pregnant patients to a cardiologist.

## *DIET*

Regular diet, or low-sodium if heart failure present.

## *PATIENT EDUCATION*

American Heart Association: <http://www.heart.org>

## *PROGNOSIS*

Sequelae are generally limited to the heart and depend on the severity of carditis during an acute attack.

## **COMPLICATIONS**

- Recurrence of ARF due to GAS reinfection
- RHD can occur 10 to 20 years after ARF, with mitral more common than aortic regurgitation, can lead to stenosis. Heart failure is worst complication.
- Jaccoud arthropathy is chronic and involves painless deformities of hands/feet.

## Codes

&NA;

### ICD10

- I00 Rheumatic fever without heart involvement
- I01.9 Acute rheumatic heart disease, unspecified
- I01.0 Acute rheumatic pericarditis

## Clinical Pearls

&NA;

- ARF is an inflammatory disease that affects multiple organ systems including the heart.
- Modified Jones criteria for diagnosis include 2 major or 1 major + 2 minor manifestation in the context of a preceding documented GAS infection.

- Treatment involves aspirin and antibiotic eradication followed immediately by long-term antibiotic prophylaxis.

# Rhinitis, Allergic

Naureen Bashir Rafiq, MBBS, MD

## BASICS

Allergic rhinitis is the collection of symptoms, involving mucous membranes of nose, eyes, ears, and throat after an exposure to allergens like pollen, dust, or dander.

## DESCRIPTION

- IgE-mediated inflammation of the nasal mucosa following exposure to an extrinsic protein; an immediate symptomatic response is characterized by sneezing, congestion, and rhinorrhea followed by a persistent late phase dominated by congestion and mucosal hyperreactivity.
- Allergic rhinitis can be classified into seasonal or perennial and can be intermittent or persistent.
- Seasonal responses are usually due to outdoor allergens like tree pollen, flowering shrubs in spring, grasses and flowering plants in summer, and ragweed and mold in fall.
- Perennial responses, or year-round symptoms, are usually associated with indoor allergens like dust mites, mold, and animal dander.
- Occupational allergic rhinitis is caused by allergens at the workplace and can be sporadic or year-round.
- Nonallergic rhinitis (e.g., vasomotor, rhinitis of pregnancy, and rhinitis medicamentosa) can occur.

## *Pediatric Considerations*

Chronic nasal obstruction can result in facial deformities, dental malocclusions, and sleep disorders.

## *Pregnancy Considerations*

Physiologic changes during pregnancy may aggravate all types of rhinitis, frequently in the 2nd trimester.

## EPIDEMIOLOGY

- Onset usually in first 2 decades, rarely before 6 months of age, with tendency declining with

advancing age.

- The mean age of onset is 8 to 11 years, and about 80% of cases have established allergic rhinitis by age 20 years.

## *Prevalence*

- ÷ 10-25% of the U.S. adult population and 9-42% of the U.S. pediatric population are affected.
- 44-87% of patients with allergic rhinitis have mixed allergic and nonallergic rhinitis, which is more common than either pure form (1).
- Scandinavian studies have demonstrated cumulative prevalence rate of 14% in men and 15% in women.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Aeroallergen-driven mucosal inflammation due to resident and infiltrating inflammatory cells, as well as vasoactive and proinflammatory mediators (e.g., cytokines)
- Inhalant allergens:
  - Perennial: house dust mites, indoor molds, animal dander, cockroach/insect detritus
  - Seasonal: tree, grass, and weed pollens; outdoor molds
  - Occupational: latex, plant products (e.g., baking flour), sensitizing chemicals, and certain animals for people working in farms and vet clinics

## *Genetics*

Complex but strong genetic predilection present (80% have family history of allergic disorders)

## *RISK FACTORS*

- Family history of atopy, with a greater risk if both parents have atopy
- Higher socioeconomic status
- Tobacco smoke can exacerbate symptoms and increase risk of developing asthma in patients with allergic rhinitis.
- Having other allergies like asthma
- Unclear evidence regarding risk due to early, repeated exposure to offending allergen and early introduction of solid food.
- Pets in house and houses infested with cockroaches can cause perennial allergic rhinitis.

## GENERAL PREVENTION

- Primary prevention of atopic disease has not been proven effective by maternal diet or maternal allergen avoidance (2).
- Exclusive breastfeeding to 6 months of age lowers risk of some atopic disorders
- Symptomatic control by environmental avoidance is the first-line treatment.
- No evidence to support use of acaricides with miteproof mattress and pillow covers, carpet and drape removal, removal of plants in the home, and pet control (2,3)[B].
- Air conditioning and limited outside exposure during allergy season (1)[B]
- HEPA air cleaners and vacuum bags of unclear efficacy
- Close doors and windows during allergy season.
- Use a dehumidifier to reduce indoor humidity.

## COMMONLY ASSOCIATED CONDITIONS

Other IgE-mediated conditions: asthma, atopic dermatitis, allergic conjunctivitis, food allergy

## DIAGNOSIS

Diagnosis is made primarily by history and physical exam.

### HISTORY

- Evaluation of nature, duration, and time course of symptoms
- History of atopic dermatitis and/or food allergies
- History of nasal congestion; rhinorrhea; pruritus of nose, eyes, ears, and/or palate; sneezing; itching; and watering eyes
- Family history of allergic diseases
- History of environmental and occupational exposure and various nasal stimuli can help differentiate between allergic and vasomotor rhinitis.

## PHYSICAL EXAM

Many findings are suggestive of but not specific for allergic rhinitis:

- Dark circles under eyes, allergic shiners (infraorbital venous congestion)
- Transverse nasal crease from rubbing nose upward; typically seen in children
- Rhinorrhea, usually with clear discharge

- Pale, boggy, blue-gray nasal mucosa
- Postnasal mucus discharge
- Oropharyngeal lymphoid tissue hypertrophy

## ***DIFFERENTIAL DIAGNOSIS***

- Infectious rhinitis: usually viral, commonly with secondary bacterial infection
  - Usually associated with sinusitis and is known as rhinosinusitis
  - Viral rhinitis averages 6 episodes/year from ages 2 to 6 years.
  - IgA deficiency with recurrent sinusitis
  - Rhinitis medicamentosa:
    - Rebound effect associated with continued use of topical decongestant drops and sprays
    - ACE inhibitors, reserpine, *&agr;*-blockers, oral contraceptive pills (OCPs), guanethidine, methyl dopa
    - Aspirin, NSAIDs
  - Vasomotor (idiopathic) rhinitis caused by numerous nasal stimuli like warm or cold air, scents and odors, light or particulate matter
  - Hormonal: pregnancy, thyroid, OCPs
  - Nonallergic rhinitis with eosinophilia syndrome (NARES)
  - Gustatory: watery rhinorrhea in response to alcohol or food
  - ØSkierØs noseØ: watery rhinorrhea in response to cold air
- Conditions associated with rhinitis:
  - Nasal polyps, tumor
  - Septal/anatomic obstruction
    - Adenoidal hypertrophy, particularly in children
    - Septal abnormality or deflected nasal septum (DNS) in adults

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Lab tests rarely needed
- Skin testing is done to identify the allergen for immunotherapy.

## *Initial Tests (lab, imaging)*

- Testing is rarely indicated.
- If diagnosis implies other causes, consider the following:
  - CBC with differential may show elevated eosinophils.
  - Increased total serum IgE level
  - Nasal probe smear may show elevated eosinophils.
- Medications that may alter lab results
  - Corticosteroids may decrease eosinophilia.
  - Antihistamines suppress reactivity to skin tests; stop antihistamines 7 days before testing.
- CT scan of sinuses is not routinely done but can be used to check for complete opacity, fluid level, and mucosal thickening.

## *Diagnostic Procedures/Other*

- Consider testing in only those cases where allergic symptoms do not respond to treatment and/or considering immunotherapy.
- Specific allergen sensitivity with allergen skin testing or radioallergosorbent testing (RAST); clinical correlation based on history is essential in interpreting results.
- Diagnostic allergen prick tests are used to select agent to determine appropriate environmental control measures, as well as to direct immunotherapy:
  - Prick or puncture: superficial injury to epidermis with application of test antigen
  - Intradermal
- RAST: more expensive and less sensitive than skin testing; typically used in patients in whom skin testing is not practical or a severe reaction is possible
- Rhinoscopy: useful to visualize intranasal anatomy and posterior pharyngeal structures, including adenoids, polyps, and larynx

---

P.927

## *Test Interpretation*

- Nasal washing/scraping: Eosinophils predominate but may see basophils, mast cells.
- Nasal mucosa: submucosal edema but without destruction; eosinophilic infiltration; congested mucous glands and goblet cells

## TREATMENT

There are three mainstays of treatment of allergic rhinitis:

- Allergen avoidance
- Medication
- Allergy immunotherapy

## GENERAL MEASURES

- Establish specific cause(s) by history and appropriate testing.
- Limit exposure to offending allergen.
- Allergen immunotherapy (desensitization)
  - Reserved when symptoms are uncontrollable with medical therapy or have a comorbidity (e.g., asthma)
  - Specific allergen extract is injected SC in increasing doses to induce patient tolerance.

## MEDICATION

Oral medication and intranasal sprays are commonly used.

### *First Line*

- Mild symptoms: 2nd-generation nonsedating antihistamines are the first-line therapy for mild to moderate allergic rhinitis (1,4).
- Adverse effects: mild sedation, mild anticholinergic effects
- Generic (cetirizine, fexofenadine, loratadine; most to least effective)
  - Levocetirizine is a new 2nd-generation nonsedating antihistamine that is effective but costly.
- Intranasal corticosteroids are the first-line therapy for moderate to severe allergic rhinitis (1,4) [A]:
  - Most effective drug class for symptoms of allergic rhinitis
  - Use nasal sprays after showering and direct spray away from septum to improve deposition on mucosal surface.
  - May be used as needed; however, less effective than regular use (1)

Adverse effects: nosebleed, nasal septal perforation, and systemic corticosteroid effects

- Systemic steroids should be considered only in urgent cases and only for short-term use.

## *Second Line*

1st-generation antihistamines, such as the following:

- Brompheniramine: 12 to 24 mg PO BID
- Chlorpheniramine: 4 mg PO q4-6h PRN
- Clemastine: 1 to 2 mg PO BID PRN
- Diphenhydramine: 25 to 50 mg PO q4-6h PRN:
  - May precipitate urinary retention in men with prostatism and/or hypertrophy
  - Adverse effects: sedation, prolonged QT interval, performance impairment, and anticholinergic effect
- Nasal antihistamines effective but may be systemically absorbed and thus cause sedation: azelastine, olopatadine
- Decongestants
  - Phenylephrine: 10 mg PO q4h PRN
  - Pseudoephedrine: 60 mg PO q4-6h PRN
  - Oxymetazoline nasal spray (Afrin): 2 to 3 sprays per nostril q10-12h PRN (max 3 days). Intranasal agents should not be used for >3 days due to rebound rhinitis. Discourage use in patients with hypertension (HTN) or cardiac arrhythmia.
- Intranasal anticholinergics such as ipratropium nasal spray 2 sprays per nostril BID to TID
  - Intranasal anticholinergics can increase efficacy in combination with steroid use.
- Leukotriene antagonists such as montelukast 10 mg/day PO
  - Should generally be used as an adjunct, not monotherapy
  - May be first line in those with concomitant asthma
- Mast cell stabilizers such as cromolyn nasal spray 1 spray per nostril TID to QID
  - May take 2 to 4 weeks of therapy for optimal efficacy
  - May be ineffective in patients with nonallergic rhinitis and nasal polyps

## ISSUES FOR REFERRAL

Refer to allergist for consideration of immunotherapy.

## ADDITIONAL THERAPIES

- Immunotherapy, either by injection (5)[A] or sublingually, which may be better tolerated by children (6)[A]
- Nasal saline use has evidence of efficacy as sole agent or as adjunctive treatment (1,7)[A].

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

No specific restrictions on activity; emphasize avoiding activity where exposure to the allergen is likely.

### Patient Monitoring

Initiation of patient education is critical.

### DIET

- No special diet unless concomitant food reactions are suspected and evaluated
- Some patients with severe sensitivity to seasonal pollens may have oral allergy syndrome, which is associated with itching in the mouth with the ingestion of fresh fruits that may cross-react with the allergens.

### PATIENT EDUCATION

- Asthma & Allergy Foundation of America, 1717 Massachusetts Ave., Suite 305, Washington, DC 20036; (800) 7-ASTHMA: <http://www.aafa.org/>
- Other helpful information available at <http://acaai.org/> and <http://www.aaaai.org/home.aspx>

### PROGNOSIS

- Acceptable control of symptoms is the goal.
- Treatment is helpful to reduce the risk of comorbidities, such as sinusitis and asthma.

### COMPLICATIONS

- Secondary infection such as otitis media or sinusitis
- Epistaxis

- Nasopharyngeal lymphoid hyperplasia
- Airway hyperreactivity with allergen exposure
- Asthma
- Facial changes, especially in children who are mouth breathers
- Sleep disturbance

Conjunctivitis, Acute

**&NA;**

## **ICD10**

- J30.9 Allergic rhinitis, unspecified
- J30.1 Allergic rhinitis due to pollen
- J30.2 Other seasonal allergic rhinitis

## **Clinical Pearls**

**&NA;**

- Nasal saline irrigation (flushing 6 to 8 oz) may be very helpful in clearing upper airway of secretions and may precede the use of nasal corticosteroids.
- 2nd-generation antihistamines and intranasal corticosteroids are first-line therapies for allergic rhinitis.
- Referral to allergist is appropriate for identification of offending allergens and consideration of immunotherapy for inadequate symptom control.

# Rocky Mountain Spotted Fever

Ginny H. Lee, MD

Alison Southern, MD, MS, FACEP

## BASICS

### DESCRIPTION

- Rocky Mountain spotted fever (RMSF) is a potentially fatal tick-borne systemic small vessel vasculitis caused by the bacterium *Rickettsia rickettsii*.
- RMSF is the most common and lethal rickettsial disease in the United States.
- Typically characterized by fever, headache, and myalgias followed by a centripetal (moving inward from the extremities toward the trunk) rash
- System(s) affected: cardiovascular, musculoskeletal, skin, CNS, renal, hepatic, and pulmonary

### EPIDEMIOLOGY

#### Incidence

- In the United States, the incidence of RMSF increased from <2 cases per million persons in 2000 to >8 per million in 2008 (1).
- Reported in all states except Hawaii, Alaska, and Maine
- North Carolina, Tennessee, Oklahoma, Arkansas, and Missouri account for ÷60% of cases. RMSF also found in areas of Canada and in Central and South America (2).
- Predominant age: All ages are susceptible; highest prevalence in children 5 to 9 years of age (2,3).
- Predominant sex: male > female, likely due to increased outdoor exposures (3,4).
- Peak incidence occurs with tick exposure, typically in late spring and summer (3).

#### Prevalence

In the United States, about 2,000 cases are reported annually (2).

- <0.1% of ticks carry virulent Rickettsial species.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Infected ticks include the American dog tick, *Dermacentor variabilis* in the eastern United States; the Rocky Mountain wood tick, *Dermacentor andersoni* in the western United States; and the Brown dog tick, *Rhipicephalus sanguineus* in the southwest (1,2).
- An adult tick releases *Rickettsia rickettsii* from its salivary glands after 6 to 10 hours of feeding (1).
- Rickettsiae proliferate inside endothelial cells by binary fission and invade contiguous vascular endothelial cells, causing a small-vessel vasculitis and the characteristic rash.
- Increased vascular permeability leads to edema, hypovolemia, and hypoalbuminemia, with subsequent end-organ injury.
- Platelets are consumed locally due to vascular injury, but coagulopathy or disseminated intravascular coagulation (DIC) is rare (4).
- Incubation time: 2 to 14 days; median 4 to 7 days
- Transplacental transmission of infection has not been demonstrated.
- RMSF can rarely be caused by direct inoculation of tick blood into open wounds or conjunctivae.

## RISK FACTORS

- Known tick bite, engorged tick, or presence of tick for >20 hours; *likelihood of infection increases with duration of tick attachment*
- Crushed tick during its removal
- Accumulated outdoor exposure or residence in a wooded area
- Contact with outdoor pets or wild animals

## GENERAL PREVENTION

In known tick-prone areas (2,4,5)

- Limit time spent in tall grasses, open areas of low bushy vegetation, and wooded areas.
- Cover exposed skin; wear a hat, long sleeves, pants and closed-toed shoes.
- Use DEET-containing insect repellents on exposed skin. Permethrin can be used on clothing.
- Tick checks: Carefully inspect the entire body after possible exposure, especially the scalp, neck, and axillae. Ticks are commonly hidden by hair. Closely inspect legs, groin, external genitalia, and waistlines.

Remove attached ticks in their entirety with finetipped tweezers. Grasp the tick close to the skin and gently pull upward. If mouth-parts separate, try to remove gently. Nail polish, petrolatum jelly, and heating do not aid in tick removal. Wear gloves if possible.

- Wash hands and site of bite thoroughly after tick removal to avoid potential mucosal inoculation.
- Prophylactic antibiotic treatment is not recommended.

## DIAGNOSIS

Delay in presentation and initiation of therapy increases risk of long-term sequelae and mortality.

### HISTORY

Consider RMSF in acute febrile illness, especially with history of potential tick exposure within previous 14 days, travels to an endemic area, and presentation in the late spring or summer. *The painless tick bite goes unnoticed 30-50% of the time. Many patients do not report a bite (2,4).*

- Early disease (days 1 to 3) presents like a viral illness with frontal headache, fever, malaise, body aches, nausea, and vomiting. RMSF is easily mistaken for gastroenteritis, pharyngitis, or mononucleosis.
- Signs and symptoms associated with RMSF with frequency of occurrence
  - Fever, usually  $>102^{\circ}\text{F}$  (99-100%)
  - Rash, macular/maculopapular/petechial, blanching (88-90%)
  - Headache (79-91%)
  - "Classic triad" of headache, fever, and rash (50-60%)
  - Myalgias (72-83%)
  - Nausea/vomiting (56-60%)
  - Abdominal pain, particularly in children (35-52%)
  - Cough, nonproductive (33%)
  - CNS dysfunction, stupor/confusion/coma/focal abnormalities (10-30%)
  - Patients may also have malaise, restlessness, arthralgia, conjunctivitis, and peripheral or periorbital edema.

### PHYSICAL EXAM

On days 3 to 4, a centripetal rash usually forms (80% of adults), involving the palms and soles, spreading centrally to arms, legs, and trunk. The rash typically starts as an erythematous, macular, or maculopapular exanthem; 50% become petechial or purpuric; blanchable.

- 20% never develop the classic rash, delaying diagnosis and resulting in a more severe outcome. Rash can be difficult to visualize on dark-skinned patients.
- Rash may be variable in appearance. *Do not rely solely on the presence or absence of the typical rash for diagnosis.*
- In severe cases, the rash can involve the entire body and mucosal membranes and may progress to necrotic or gangrenous lesions.
- The rash is not associated with pruritus or urticaria; when present, this makes RMSF less likely.
- Hepatosplenomegaly (12-16%)
- Lymphadenopathy (27%)

## ***DIFFERENTIAL DIAGNOSIS***

- Viral exanthems (e.g., measles, rubella, roseola)
- Meningoencephalitis (viral meningitis or encephalitis, bacterial meningitis)
- Meningococemia
- Typhus
- Ehrlichiosis
- Lyme disease
- Leptospirosis
- Toxic shock syndrome
- Adenovirus infection
- Drug reaction or serum sickness
- Mononucleosis
- Kawasaki disease

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Diagnosis is often clinical in patients with exposure history in an endemic area. Retrospective confirmation by serology. Do not delay treatment awaiting serology.

### ***Initial Tests (lab, imaging)***

- Specific laboratory diagnosis
  - Serum indirect fluorescent antibody (IFA): Titer of >1:64 is diagnostic. A 4-fold increase of

acute and convalescent titers confirms an active case of RMSF (1).

- Antibodies usually develop 7 to 10 days after onset of symptoms; optimal time for testing, therefore, is 14 to 21 days after symptom onset. *Do not delay treatment.*
  - Early treatment may limit antibody formation.
  - Seropositivity increases with age in endemic states. Positive spotted fever group *Rickettsia* antibody does not necessarily signify an acute infection.
- Nonspecific laboratory changes (incidence) (4)
    - WBC count: variable and frequently normal
    - Thrombocytopenia (32-52%)
    - Hyponatremia, mild (19-56%)
- 
- Anemia, mild (5-24%)
  - Azotemia (12-14%)
  - Elevated AST (36-62%)
  - Coagulation derangements are uncommon, despite vascular damage.
  - CSF is usually normal; some patients may have mononuclear pleocytosis, elevated protein, and normal glucose.
- Other than occasional nonspecific pneumonic infiltrates on chest radiograph, imaging procedures are rarely helpful.

P.929

### *Diagnostic Procedures/Other*

Skin biopsy can offer definitive diagnosis. A 3-mm punch biopsy is sufficient to perform a rapid direct fluorescent antibody (DFA) test (sensitivity 70%, specificity 100%). Electron microscopy (EM) can also identify rickettsiae within endothelial cells. Western immunoblotting confirms the specific spotted fever group species (1,2,4).

### *Test Interpretation*

- Rickettsiae can be demonstrated within endothelial cells by DFA or EM.
- Petechiae due to the vasculitis may be seen on various organ surfaces (e.g., liver, brain, or epicardium).
- Secondary thromboses and tissue necrosis may be seen.

# TREATMENT

## MEDICATION

### *First Line*

Doxycycline is the treatment of choice in both adults and children (1,2,3,4).

- Untreated rickettsial infections have a high rate of morbidity and mortality. Other antibiotics are considerably less effective.
- The ONLY contraindication to doxycycline is severe allergy.
- For adults: 100 mg PO or IV q12h for 7 to 10 days, treat for at least 3 days after the fever resolves.
- For children weighing <45 kg (100 lbs): 2.2 mg/kg/dose (max 200 mg) q12h for 7 to 10 days, treating for at least 3 days after fever resolves; those <sup>3</sup>45 kg, refer to adult dosing (4)
- Fever should subside within 24 to 72 hours with early treatment; may take longer if patient is severely ill.
- If patient has no response to doxycycline, consider an alternate diagnosis. Rickettsial resistance to doxycycline has NOT been documented.
- Side effects of doxycycline
  - Dyspepsia. Take medication with food and water. Avoid dairy products, iron preparations, or antacids, as they may inhibit drug absorption.
  - Photosensitivity may occur. Minimize sun exposure and use sunscreen.
  - Risk of dental staining in children <8 years old is minimal if short courses are administered.

### *Second Line*

- Chloramphenicol: 50 mg/kg/day IV divided q6h (4 g/day max); same dose in renal failure
  - Associated with aplastic anemia and an increased case mortality
- Fluoroquinolones have not been evaluated clinically in RMSF, but they have shown in vitro activity against *R. rickettsii*.
- Sulfa-containing drugs may worsen tick-borne infections and are contraindicated.

### *Pregnancy Considerations*

- Doxycycline is appropriate for this life-threatening infection in pregnancy if suspicion is high,

despite the potential risk to fetal bones/teeth.

- Chloramphenicol may be considered during the first 2 trimesters but should be avoided in the 3rd trimester due to potential for gray baby syndrome.

## ***ISSUES FOR REFERRAL***

- Consider infectious disease consult.
- Report cases of RMSF to public health authorities.

## ***ADDITIONAL THERAPIES***

Patients with neurologic injury or loss of limbs caused by gangrene may require prolonged physical and cognitive therapy.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- CNS dysfunction
- Nausea/vomiting preventing oral antibiotic therapy
- Immunocompromised patients
- Specific acute organ failure
- Failure of oral pain management
- ICU placement for acutely ill patients with shock

### ***IV Fluids***

Aggressive fluid resuscitation and electrolyte management may be required in critically ill patients.

### ***Discharge Criteria***

- Resolution of fever
- Ability to take oral therapy and nutrition

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Hospitalize patients with moderate to severe disease

- Patients with mild disease may be treated as outpatients. Close follow-up is important to identify complications.
- Infection does not confer lifelong immunity.

## *Patient Monitoring*

- Outpatients should be seen every 2 to 3 days until symptoms resolve.
- Follow up CBC, electrolytes, LFTs if clinically indicated.

## *DIET*

Consider nutritional supplementation if intake is poor.

## *PROGNOSIS*

- Prognosis is closely related to timely administration of appropriate antibiotics. Treatment before day 5 of illness can prevent morbidity and mortality (6).
- When treated promptly, prognosis is usually excellent with resolution of symptoms over several days and no sequelae.
- If complications develop, course may be more severe and long-term sequelae (especially neurologic sequelae) more likely (6).
- Children aged 5 to 9 years and elderly >70 years are at higher risk of morbidity and/or mortality (4,6).
  - Black males with G6PD deficiency are at highest risk for fulminant RMSF, in which death can occur within 5 days (4).

## **COMPLICATIONS**

- Encephalopathy (30-40%); most commonly transient impaired level of consciousness or meningismus
- Seizures, focal neurologic deficit (10%)
- Renal injury (10%)
- Hepatitis (10%)
- Congestive heart failure (CHF) (5%)
- Respiratory failure (5%)
- Proximal muscle weakness, changes in personality, paresthesias, distal necrosis, and deafness

## Codes

&NA;

### ICD10

A77.0 Spotted fever due to *Rickettsia rickettsii*

## Clinical Pearls

&NA;

- Diagnosis of RMSF requires a high index of clinical suspicion. Painless tick bites often go unnoticed, and some patients may never develop a rash.
- Treatment should begin immediately in suspected cases. Doxycycline is indicated for treatment of RMSF in both adults AND children. The only absolute contraindication is severe allergy to the drug.
- Lab testing is nonspecific and frequently normal.
- Although prevalence is highest in central and southeastern United States, cases have been

reported in almost all states.

# Roseola

Jeffrey D. Quinlan, MD, FAAFP

## BASICS

Omnipresent infection occurring in infancy and childhood. Majority of cases are caused by human herpesvirus 6 (HHV-6). May be associated with other diseases including encephalitis

## DESCRIPTION

- Acute infection of infants or very young children (1)
- Causes a high fever followed by a skin eruption as the fever resolves (1)
- Transmission via contact with salivary secretions or respiratory droplet (1)
- Incubation period of 9 to 10 days (2)
- System(s) affected: skin/exocrine, metabolic, gastrointestinal, respiratory, neurologic
- Synonym(s): roseola infantum, exanthem subitum; pseudorubella; sixth disease; 3-day fever (3)

## Pediatric Considerations

A disease of infants and very young children (4)

## EPIDEMIOLOGY

- Predominant age
  - HHV-6
    - Infants and very young children (<2 years old) (5)
    - Peak age infection 6 to 9 months, rarely congenital or perinatal infection (1)
    - 95% of children have been infected with HHV-6 by 2 years of life.
  - HHV-7
    - Later childhood
    - Mean age of infection 26 months
    - >90% population with HHV-7 by 10 years (1)

- Predominant sex: male = female (1)
- No seasonal variance

### *Incidence*

CommonÑaccounts for 20% ED visits for febrile illness among children 6 to 8 months (6)

### *Prevalence*

- Peak prevalence is between 9 and 21 months (5).
- Nearly 100% population carrying HHV-6 by 3 years (1)
- Approximately 20% patients with primary HHV-6 have roseola (6).

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- HHV-6 and HHV-7 (4)
- Majority of cases (60-74%) due to HHV-6
  - HHV-6B > HHV-6A (4)
  - HHV-6A seen in children in Africa
  - HHV-6 binds to CD46 receptors on all nucleated cells (4).
- Primary infection typically through respiratory droplets or saliva
- Congenital infection/vertical transmission occurs in 1% of cases (1).
  - Transplacental transmission
  - Chromosomal integration (clinical significance unknown)
- Lifelong latent or persistent asymptomatic infection occurs after primary infection (1).
  - 80-90% population intermittently sheds HHV-6/HHV-7 in saliva (4).
  - Patients are viremic from 2 days prior to fever until defervescence and onset of rash.
  - HHV-6 latency is also implicated in CSF (6).

### *Genetics*

HHV-6 is integrated into the chromosomes of 0.2-3.0% of the population. This leads to vertical transmission of the virus. Clinical significance of this is unknown (1).

## RISK FACTORS

- Female gender (5)
- Having older siblings (5)
- At-risk adults: immunocompromised (7)
  - Renal, liver, other solid organ, and bone marrow transplant (BMT) (5)
  - HHV-6 reactivation can occur in 1st week post-transplant (7). HHV-6 viremia occurs in 30-45% of BMT within the first several weeks after transplantation (6).
    - Usually asymptomatic (6)
    - Up to 82% of HHV-6 reactivation/reinfection in solid organ transplant (7)
- Nonrisk factors (5)
  - Child care attendance
  - Method of delivery
  - Breastfeeding (HHV does not appear to pass through breast milk)
  - Maternal age
  - Season

## DIAGNOSIS

### HISTORY

- 3 to 5 days abrupt fever 102.2-104.0°F (39-40°C) not associated with a rash (1)
- The child may be fussy during this prodrome (1,6).
- Sudden drop of fever associated with appearance of rash (1)
  - Rash on trunk then spreads centrifugally mainly to neck, possibly also to peripheral extremities, and face.
- Diarrhea (5)
- Mild upper respiratory symptoms (5)
- Rhinorrhea (5)
- Febrile seizure occurs in 13% of cases (1).

## PHYSICAL EXAM

- Rash (exanthem subitum) (1)
  - Rose-pink macules and/or papules that blanch
  - First appears on the trunk then peripherally
  - May occur up to 3 days after fever resolves (1)
  - Fades within 2 days
  - Occurs in approximately 20% of patients in the United States (1)
- Mild inflammation of tympanic membrane, pharynx, and/or conjunctiva (1,6)
- Ulcers on soft palate and uvula (Nagayama spots) (1)
- Cervical lymphadenopathy (1)
- Periorbital edema (4)

## *DIFFERENTIAL DIAGNOSIS*

- Enterovirus infection (8)
- Adenovirus infection (1)
- Epstein-Barr virus
- Fifth disease—parvovirus B19 (8)
- Rubella (8)
- Scarlet fever (8)
- Drug eruption (1)
- Measles (1)

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Primarily a clinical diagnosis not requiring laboratory or radiologic testing (1)
- Tests often cannot differentiate latent or active disease (9).
- Specific diagnosis only necessary in severe cases, unclear diagnosis where more serious disease needs to be ruled out, or if considering antiviral therapy (1).

### *Initial Tests (lab, imaging)*

- HHV-6 and HHV-7 by PCR (1,7)
  - Serum, whole blood, CSF, or saliva

- Becoming more widely available
- HHV-6 IgM immunofluorescence (1)
  - Diagnostic for acute infection
  - Spike seen in 1st week of illness
- HHV-6 IgG immunofluorescence (1)
  - Check at diagnosis and then 2 weeks later.
  - Use with IgM to show primary infection.
  - Negative initial test and rise on follow-up suggests primary infection.
- Viral culture (7)
  - Rarely done
  - No clinical use (very time consuming)
- Other laboratory findings (1)
  - Decreased total leukocytes, lymphocytes, and neutrophils
  - Elevated transaminases
  - Thrombocytopenia

### *Diagnostic Procedures/Other*

- Urine culture: to rule out UTI as source of fever (2)
- Chest x-ray (CXR): if a child has respiratory symptoms

---

P.931

## **TREATMENT**

No treatment necessary, resolves without sequelae (1)[C].

## **GENERAL MEASURES**

- Symptomatic relief including antipyretics (1)[C]
- Hydration (1)[C]

## **MEDICATION**

## *First Line*

- No specific first-line treatment in immunocompetent hosts beyond supportive measures (4)[C]
  - Antivirals are not recommended in immunocompetent.
- No approved antiviral treatment in immunocompromised (4).
- Second-line IV ganciclovir, cidofovir, foscarnet tested in vitro studies in stem cell transplant patients
  - HHV-6B susceptible: ganciclovir and foscarnet (7)[C]
  - HHV-6A and HHV-7 are more resistant to ganciclovir (7).
- Antivirals suggested in individual cases of encephalitis (associated with reactivation of HHV-6) (7)
- In bone marrow and stem cell transplant recipients receiving immunosuppression, ganciclovir prophylaxis is effective in preventing reactivation of HHV-6 (10)[B].

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- During febrile prodrome, monitor for dehydration.
- None after typical rash appears and fever resolves
- Mean duration of illness is 6 days (6).
- If febrile seizures occur, they will cease after fever subsides and will not likely recur (6).
- Symptomatic reactivation in immunocompromised (1)

#### *DIET*

Encourage fluids.

### *PATIENT EDUCATION*

- Parental reassurance that this is usually a benign, self-limited disease (1).
- There is no specific recommended period of exclusion from out-of-home care for affected children.

Patient is viremic a few days prior to fever until time of defervescence and rash onset.

## PROGNOSIS

- Course: acute, complete recovery without sequelae (1)
- Reactivation in immunocompromised patients is common (6).

## COMPLICATIONS

- Febrile seizures
  - 13% patients with roseola (1,6)
  - Accounts for 1/3 of primary seizures in children <2 years old (1)
- Medication hypersensitivity syndromes (drug reaction with eosinophilia and systemic symptoms) (4)
- Reactivation can occur in transplant patients, HIV-1 infection, and other immunocompromised individuals (6).
- Meningoencephalitis occurs in immunocompetent and in immunosuppressed patients (6). Poor association with multiple sclerosis (6)
- Pityriasis rosea (1)
- Possible association with progressive multifocal leukoencephalopathy (6)

## Codes

**&NA;**

### ICD10

- B08.20 Exanthema subitum [sixth disease], unspecified
- B08.21 Exanthema subitum [sixth disease] due to human herpesvirus 6
- B08.22 Exanthema subitum [sixth disease] due to human herpesvirus 7

## Clinical Pearls

**&NA;**

- Roseola infection should be suspected if an infant or young child presents with a high temperature without other clinical findings.
- As the fever abates, a macular rash will be seen on the trunk, with eventual spread to the face and extremities in 20% of patients.
- Roseola is a clinical diagnosis, and laboratory testing is not necessary for most children with classic presentation.
- For atypical presentations, complications, and immunocompromised hosts, several laboratory tools are available, including serologic testing for antibody, viral PCR testing, and viral culture.
- Infection is typically self-limiting and without sequelae.
- Usually only symptomatic treatment is needed.
- Consider prophylaxis in patients undergoing bone marrow or stem cell transplant and receiving immunosuppressive therapy.

# Rotator Cuff Impingement Syndrome

Faren H. Williams, MD, MS

Minjin Fromm, MD

## BASICS

### DESCRIPTION

- Compression of rotator cuff tendons and subacromial bursa between the humeral head and the structures that makes up the coracoacromial arch and proximal humerus
- Most common cause of atraumatic shoulder pain in patients >25 years of age
- Primary symptom is pain that is most severe when the arm is abducted between 60 and 120 degrees (the "painful arc").
- Classically divided into three stages
  - Stage I: acute inflammation, edema, or hemorrhage of the underlying tendons due to overuse (typically in those age <25 years)
  - Stage II: progressive tendinosis that leads to partial rotator cuff tear along with underlying thickening or fibrosis of surrounding structures (commonly, ages 25 to 40 years)
  - Stage III: full-thickness tear (typically in patients age >40 years)

### EPIDEMIOLOGY

#### *Incidence*

- Shoulder pain accounts for 1% of all primary care visits.
- Peak incidence of 25/1,000 patients/year occurs in patients aged 42 to 46 years.
- Impingement responsible for 18-74% of shoulder pain diagnoses.

#### *Prevalence*

Prevalence of shoulder pain in general population ranges from ~7% to 30%.

### RISK FACTORS

- Repetitive overhead motions (throwing, swimming)

- Glenohumeral joint instability or muscle imbalance
- Acromioclavicular arthritis or osteophytes
- Thickened coracoacromial ligament
- Shoulder trauma
- Increasing age
- Smoking

## **GENERAL PREVENTION**

- Proper throwing and lifting techniques
- Proper strengthening to balance rotator cuff and scapula stabilizer muscles

## **DIAGNOSIS**

### **HISTORY**

- Gradual increase in shoulder pain with overhead activities (sudden onset of sharp pain suggests a tear)
- Night pain is common, exacerbated by lying on the affected shoulder or sleeping with the affected arm above the head.
- Anterolateral shoulder pain with overhead activities
- May progress to weakness and decreased range of motion if shoulder is not used through full range of motion

### **PHYSICAL EXAM**

- Examine patient for atrophy/asymmetry. Observe how the patient takes off his or her shirt as part of the exam.
- Neer impingement test: Examiner stabilizes the scapula and moves the affected upper extremity through a flexion arc. Patient reports pain with flexion of the shoulder. Sensitivity: 78%. Specificity: 58% (1)[A]
- Hawkins-Kennedy impingement test: Examiner places the arm in 90 degrees of forward flexion and then gently internally rotates the arm. End point for internal rotation is when the patient feels pain or when the rotation of the scapula is felt or observed by the examiner. Test is positive when patient experiences pain during the maneuver. Sensitivity: 74%. Specificity: 57% (1)[A]

Empty can test (supraspinatus): Examiner asks the patient to elevate and internally rotate the arm with thumbs pointing downward in the scapular plane. Elbow should be fully extended. Examiner applies downward pressure on upper surface of the arm. Test is positive when patient complains of pain with resistance. Sensitivity: 69%. Specificity: 62% (1)[A]

- Lift-off test (subscapularis): Patient internally rotates the shoulder, placing the hand on ipsilateral buttock, then lifts hand off buttock against resistance. A tear in the subscapularis muscle produces weakness of this action. Sensitivity: 42%. Specificity: 97% (1)[A]
- Drop-arm test: Patient fully elevates arm and then slowly reverses the motion. If the arm is dropped suddenly or the patient has extreme pain, the test is positive for a possible rotator cuff tear. Sensitivity: 21%. Specificity: 92% (1)[A]
- Resisted external rotation: weakness suggestive of infraspinatus and/or teres minor tendon involvement
- Examine cervical spine to rule out cervical pathology as source of shoulder pain.
- Neurovascular exam of the upper extremity

## ***DIFFERENTIAL DIAGNOSIS***

- Labral injury
- Acromioclavicular arthritis (more common in older patients; positive cross-arm test ñ pain when affected arm is fully adducted across the chest in the horizontal plane)
- Adhesive capsulitis (rotator cuff tendonitis leads to decreased use and atrophy of rotator cuff muscles, followed by contracture; linked to diabetes and may be related to prior trauma)
- Anterior shoulder instability (prior trauma; more common in patients <25 years old)
- Multidirectional instability
- Biceps tendonitis or rupture (perform Speed and Yergason tests and look for visible or palpable defect of biceps ñ Popeye sign Ó)
- Calcific tendonitis
- Cervical radiculopathy (spinal or foraminal stenosis, can test with Spurling maneuver)
- Glenohumeral arthritis (evaluate with plain films)
- Suprascapular nerve entrapment (look for focal muscle atrophy of supra- or infraspinatus)
- Traumatic rotator cuff tear

## ***DIAGNOSTIC TESTS & INTERPRETATION***

## *Initial Tests (lab, imaging)*

- Plain-film radiographs of the shoulder (three views): anteroposterior, axillary, scapular Y views
- Plain films may reveal:
  - Osteoarthritis of the acromioclavicular and glenohumeral joints
  - Superior migration of the humeral head (indicative of a large rotator cuff tear)
  - Cystic change of the humeral head and sclerosis of the inferior acromion (indicative of chronic rotator cuff disease)
  - Calcific tendonitis
- MRI is used to definitively assess rotator cuff tendinopathy, partial tears, and complete tears.
- MR arthrogram is preferred for labral pathology.
- Ultrasound is sensitive and specific for rotator cuff tears but is highly operator-dependent.
- CT scan is preferred for bony pathology or for those unable to undergo MRI.

## *Diagnostic Procedures/Other*

- Lidocaine injection test
  - Inject lidocaine into the subacromial space:
    - Repeat impingement tests; if pain is completely relieved and range of motion is improved, likely impingement syndrome (rather than cuff tear).
  - Allows for more accurate strength testing on physical examination:
    - If strength is intact, rule out rotator cuff tear.
    - If range of motion does not improve in any plane, more likely adhesive capsulitis
  - Some pain relief and improved range of motion occurs after lidocaine injection with
    - Glenoid labral tear
    - Capsular strain
    - Glenohumeral osteoarthritis
    - Glenohumeral instability
- A lack of any pain relief suggests other sources or inappropriate placement of injection.

## *Test Interpretation*

May have tendinosis, tendonitis, or muscle/tendon tear

## TREATMENT

Anti-inflammatory agents plus aggressive rehabilitation can improve and fully resolve rotator cuff tendonitis in most patients.

P.933

### GENERAL MEASURES

- Rest
- Ice or heat for symptom relief
- Activity modification, with avoidance of aggravating activities, particularly overhead motions
- Range-of-motion exercises
- Rotator-cuff and adjacent muscle strengthening to enhance stability and prevent further injuries

### MEDICATION

#### *First Line*

NSAIDs or other analgesic, often for 6 to 12 weeks

### ISSUES FOR REFERRAL

Failure of conservative treatment, persistent pain, weakness, or complete tear of rotator cuff

### ADDITIONAL THERAPIES

- Supervised- or home-exercise regimens provide clinically significant pain reduction and improve function (2)[A].
- Physical therapy is effective for short-term and longterm recovery of function (3)[A]:
  - Initial goal is to restore range of motion.
  - After pain resolves, gradually strengthen rotator cuff muscles in internal rotation, external rotation, and abduction.

### COMPLEMENTARY & ALTERNATIVE MEDICINE

Acupuncture is of potential benefit to reduce pain and improve function, particularly when used with physical therapy (4)[A].

## ***SURGERY/OTHER PROCEDURES***

- Steroid injections may have a significant benefit on pain and function in the short term but do not appear to have a significant long-term effect (5)[A]:
  - Risk for rotator cuff tears not significantly increased in those receiving subacromial steroid injections (6)[C].
- No evidence that surgery is superior to conservative management, or that one surgical technique is superior to another for impingement syndrome (7)[A].
- Platelet-rich therapies for musculoskeletal soft tissue injuries are increasingly common.
  - No apparent effect of platelet-rich plasma injection during arthroscopic rotator cuff repair on overall retear rates or shoulder-specific outcomes (8)[A],(9).
- Extracorporeal shock wave therapy is currently under study as an emerging treatment for calcific tendonitis (10).

## **ONGOING CARE**

### ***PATIENT EDUCATION***

- Physical rehabilitation is necessary, both in conservative course of treatment (i.e., NSAIDs, physical therapy, home exercises) and with surgical intervention. An aggressive trial of rehabilitation should be encouraged prior to extensive testing or surgical intervention. Providing pain relief prior to beginning a program of physical therapy improves adherence and outcomes.
- Symptoms often recur if not fully addressed.

### ***PROGNOSIS***

- Variable, depends on underlying pathology
- Most patients improve with conservative management. Recovery can be slow.
- Patients with more severe symptoms—those with symptoms for >1 year—are less likely to respond well with conservative therapies.

### **COMPLICATIONS**

- Progression of injury
- Tendon retraction in complete rotator cuff tear

### ICD10

- M75.40 Impingement syndrome of unspecified shoulder
- M75.110 Incompl rotatr-cuff tear/ruptr of unsp shoulder, not trauma
- M75.120 Complete rotatr-cuff tear/ruptr of unsp shoulder, not trauma

## Clinical Pearls

## **&NA;**

- Consider impingement syndrome in patients involved with repetitive overhead activities (e.g., swimming, throwing) who present with shoulder pain.
- Atraumatic shoulder pain in middle age often represents rotator cuff tendonitis.
- Supraspinatus tendon is most commonly affected in impingement syndrome.
- Neer and Hawkins tests specifically check for shoulder impingement.
- The empty can maneuver tests for weakness of supraspinatus muscle.
- The drop-arm test is specific for rotator cuff tear.
- Physical therapy over 6 to 12 weeks promotes return to function
- Most patients with shoulder impingement respond well to conservative management. Those who don't should be referred for surgical evaluation.

# Salivary Gland Calculi/Sialadenitis

Jason E. Cohn, DO, MS

Mark Weitzel, DO

Seth Zwillenberg, MD

## BASICS

### DESCRIPTION

- Inflammation and/or infection involving one or more salivary gland
- Sialolithiasis is the cause of  $\div 90\%$  of all obstructive salivary gland diseases.
- Salivary obstruction is usually characterized by a painful swelling of the affected gland when eating, known as  $\text{\O}$ mealttime syndrome. $\text{\O}$
- The submandibular gland is more commonly affected (80-90% of cases) by sialolithiasis and infection than the parotid gland. Submandibular stones occur more commonly due to higher mucinous content of saliva, longer course of Wharton duct, slow salivary flow, and saliva flow against gravity.
- Can be acute or chronic
  - Types: infectious, obstructive (sialolithiasis), and autoimmune

### EPIDEMIOLOGY

#### Incidence

- Predominant age: Peak incidence is 30 to 60 years.
- Most common in debilitated and dehydrated patients
- 49% men and 51% women, average age 47.5 years; 82% submandibular stones and 18% parotid stones, 44% had a positive smoking history, and 20% of patients were taking diuretics.

#### Prevalence

- Salivary calculi can be found in 1.2% of the adult population.
- Only 5% of all cases occur in the pediatric population.

In those with sialographic evidence of benign intraductal obstruction, the obstruction is caused by salivary calculi in >73% of cases.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Decreased salivary outflow from anticholinergics, dehydration, or radiation is thought to allow bacterial infection of salivary glands.
- Salivary calculi form by deposition of calcium phosphate. Predisposing factors include salivary stasis, retrograde bacterial contamination from the oral cavity, increased alkalinity of saliva, and physical trauma to salivary duct or gland.
- Gout is a well-known systemic disease known to be associated with salivary stone development. In gout, sialoliths are composed of uric acid.
- Sialadenitis occurs by recurrent inflammatory reactions that result in progressive acinar destruction with fibrous replacement and sialectasis.
- Bacterial sialadenitis: *Staphylococcus aureus*, *Streptococcus viridans*, *Streptococcus pyogenes*, *Haemophilus influenzae*, *Escherichia coli*, *Pseudomonas aeruginosa*, and group B streptococci (neonates and prepubescent children)
- Viral sialadenitis: mumps, cytomegalovirus (CMV), Epstein-Barr virus (EBV), HIV, and enteroviruses

## Pediatric Considerations

The two most common causes of sialadenitis in children are mumps and idiopathic juvenile recurrent parotitis.

## Genetics

Polygenic cause, with several loci under investigation

## RISK FACTORS

- Dehydration
- Anticholinergic use
- Antihistamine use
- Diuretic use
- Poor oral hygiene
- Malnutrition
- Head/neck radiation

- Tuberculosis (TB)
- HIV
- Failure to immunize (mumps)
- Gout
- Diabetes mellitus
- Hypothyroidism
- Renal failure
- Duct strictures
- Previous intraoral procedures

## *GENERAL PREVENTION*

- Adequate hydration
- Maintain proper oral care and hygiene.
- Avoid antihistamines, anticholinergics, and other causes of xerostomia, especially if other risk factors are present.

## *COMMONLY ASSOCIATED CONDITIONS*

- Postoperative dehydration
- Radiation-induced xerostomia
- Drug-induced xerostomia
- Sjögren syndrome
- Hypercalcemia

## **DIAGNOSIS**

### **HISTORY**

- Acute onset of pain and swelling over the affected salivary gland, especially postprandial
- Dental pain, discharge, foul breath (halitosis), and pain with chewing
- Fever, unintentional weight loss
- Xerostomia
- Recent dental work, surgery

- Immunization history
- Radiation, TB, and HIV exposure
- History of alcoholism, bulimia, and malnutrition (suggest sialadenosis)

## *PHYSICAL EXAM*

- Palpate all salivary glands, floor of mouth, tongue, and neck to assess symmetry, tenderness, induration, edema, presence of stones, and lymphadenopathy.
- Examine duct openings for purulent discharge and saliva.
- Palpate gland gently to express purulent material.
- Examine eyes for interstitial keratitis.
- Note lingual papillary atrophy and/or loss of tooth enamel.

## *Pediatric Considerations*

Stones in children are traditionally smaller in size, within the duct distally, and present with a shorter symptom duration.

## *DIFFERENTIAL DIAGNOSIS*

- Acute bacterial parotitis
- Chronic bacterial parotitis
- Idiopathic juvenile recurrent parotitis
- Dental abscess
- Mumps
- TB
- HIV (in pediatric populations)
- EBV, CMV, enteroviruses
- Tularemia
- Cystic fibrosis
- Lupus
- Sjögren syndrome
- Alcoholism
- Bulimia

- Hypothyroidism
- Pleomorphic adenoma
- Lymphoma
- Sarcoidosis
- Collagen vascular disease
- Metal poisoning

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- CBC, electrolytes
- Culture and sensitivity of any expressed pus
- CT scan with IV contrast is the preferred imaging modality.
- Ultrasound can localize abscesses as well as stones. Stones appear hyperechoic with posterior shadowing (1)[B].
- Sonopalpation (concurrent ultrasound with transoral palpation) proved to have a sensitivity and specificity of 96.6% and 90% in finding a calculi (2)[B].
- Minor salivary gland biopsy.

### *Follow-Up Tests & Special Considerations*

- If autoimmune process is suspected, consider ordering appropriate labs, such as autoantibody titers: Sjögren syndrome A (SS-A) and Sjögren syndrome B (SS-B), rheumatoid factor (RF), and antinuclear antibodies (ANAs). Erythrocyte sedimentation rate (ESR) may also be conducted.
- Consider serial CT scans with contrast to evaluate disease resolution.
- Ultrasound can identify indicators of persistent obstruction in patients undergoing sialolithotomy (1)[B].

### *Diagnostic Procedures/Other*

- Sialography to evaluate sialolithiasis and other obstructive lesions
- Sialendoscopy to find and remove sialoliths. In one study, sialendoscopy confirmed 221 (79%) parotid and 812 (93%) submandibular stones (3)[A].
- One study revealed that sonography, cone beam CT and sialendoscopy all had excellent specificity and positive predictive value in diagnosing stones. However, sialendoscopy was

superior in sensitivity and negative predictive value (4)[B].

- When sialendoscopy fails, a novel ultrasoundguided needle localization approach has been proposed (5)[B].
- Technetium 99m pertechnetate scintigraphy showed decreased gland excretion and decreased uptake in patients with sialolithiasis (6)[B].

## *Test Interpretation*

In chronic sialadenitis, loss of acini, fibrosis, and periductal lymphocytosis are evident; degree indicates chronicity.

P.935

## **TREATMENT**

### **GENERAL MEASURES**

- Maintain hydration.
- Apply warm compresses with massage.
- Maintain good oral hygiene.
- Antibiotics if indicated by diagnosis

### **MEDICATION**

#### **First Line**

- Antistaphylococcal penicillins (nafcillin, dicloxacillin) are indicated in areas where methicillin-resistant *Staphylococcus aureus* (MRSA) is not predominant.
- Penicillin-allergic: Use clindamycin 300 mg PO q8h
- Gram negative: third-generation cephalosporin or fluoroquinolone
- Anaerobic: metronidazole or clindamycin
- Antibiotic coverage should be narrowed once culture and sensitivity are available.
- Continue antibiotic therapy for 10 to 14 days.

#### **Second Line**

- 1st-generation cephalosporin (cephalexin or cefazolin) or clindamycin is also indicated for empiric coverage.

- If MRSA than Vancomycin.

## *ISSUES FOR REFERRAL*

In the case of poor dentition and dental abscess, refer patient to a dentist.

## *ADDITIONAL THERAPIES*

In the case of chronic sialadenitis with strictures, consider sialostent placement.

## *SURGERY/OTHER PROCEDURES*

- Submandibular stones found in the anterior floor of the mouth can be excised intraorally (sialodochoplasty), whereas those in the hilum require gland excision. Parotid stones usually require parotidectomy (7)[A].
- Good results in patient symptom relief, quality of life and safety have been reported in sialadenitis and sialolithiasis using sialendoscopy (7,8,9,10)[A]. However, one study revealed a complication rate of 3.23%. Complications include strictures, ranulas, and lingual nerve injury (11)[C].
- Incision and drainage of parotid abscess is indicated after failing 3 to 5 days of medical management.
- Sialoliths and stenoses can be successfully treated by radiologically or fluoroscopically controlled or sialendoscopically based methods in ~80% of cases. Extracorporeal shock wave lithotripsy (ESWL) is successful in up to 50% of cases.
- Transoral duct slitting is an important method for extraparenchymal submandibular stones, with a success rate of 90%.
- Recent evidence shows that larger stones can be successfully and safely treated with holmium: YAG laser lithotripsy (12, 13)[B].

## *Pediatric Considerations*

The most effective diagnostic and therapeutic modality for children with sialadenitis is sialendoscopy with stone retrieval (14)[B].

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Consider lemon drops or other sialogogues to promote salivation. In one study, postoperative use of sialogogues nearly halved rates of sialadenitis (15)[C].

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Parotid abscess
- Sepsis
- Inability to tolerate PO intake
- Airway, breathing, circulation
- Check vital signs, with particular attention to blood pressure, as patient may be septic secondary to abscess formation.
- Evaluate airway patency.

### *Nursing*

Responsibilities may include ensuring excellent oral hygiene and avoiding administration of drugs that cause decreased production or flow of saliva.

### *Discharge Criteria*

- Exclude abscess or sepsis.
- Ensure ability to tolerate PO intake.
- Stable vital signs

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Provide regular follow-up visits for patients with chronic sialadenitis.
- Avoid prescribing medications that cause xerostomia.

### *Patient Monitoring*

Continue to monitor patients with chronic sialadenitis, as decreased salivary gland function due to fibrosis and loss of acini can lead to acute exacerbations.

### *DIET*

- Avoid sialogogues during acute attacks.
- Maintain adequate hydration on an outpatient basis.

### *PATIENT EDUCATION*

Educate patients on maintaining excellent oral hygiene.

- Educate patients on maintaining good hydration.

## PROGNOSIS

- Generally excellent, with acute symptoms resolving in about a week with appropriate treatment
- Patients with autoimmune etiology may have prolonged course due to systemic involvement.

## COMPLICATIONS

Abscess, dental caries, recurrent sialadenitis, facial nerve impingement, Ludwig angina

Koch M, Zenk J, Iro H. Algorithms for treatment of salivary gland obstructions. *Otolaryngol Clin North Am*. 2009;42(6):1173-1192.

## Codes

&NA;

## ICD10

- K11.5 Sialolithiasis
- K11.20 Sialoadenitis, unspecified
- K11.21 Acute sialoadenitis

## Clinical Pearls

### **&NA;**

- Sialadenitis occurs mainly in debilitated patients who lack ability to control hydration.
- Sialadenitis is associated with conditions that predispose patient to xerostomia.
- Mainstay of treatment is hydration, good oral hygiene, sialogogues, and possible surgical excision.
- Many cases are now being successfully and safely treated with sialendoscopy.

# Salmonella Infection

Justin Thomas Ertle, BS, MD

Marie L. Borum, MD, EdD, MPH

## BASICS

### DESCRIPTION

- Infection caused by any serotype of the bacterial genus *Salmonella*, a gram-negative anaerobic bacillus
- Nontyphoidal *Salmonella* typically causes gastroenteritis via foodborne infection and sporadic outbreaks. Less commonly causes infection outside the gastrointestinal tract

#### Clinical syndromes

- Enteric fever (see Typhoid Fever)
- Nontyphoidal gastroenteritis
  - Chronic carrier state (> 1 year)
- Nontyphoidal invasive disease
  - Bacteremia
    - Endovascular complications
    - Localized infection outside GI tract

### Geriatric Considerations

Patients >65 years old have increased risk of developing invasive disease with bacteremia and endovascular complications due to comorbidities (atherosclerotic endovascular lesions, prostheses, etc.) that increase risk of seeding (1).

### Pediatric Considerations

Neonates (<3 months) are more susceptible to invasive disease and complications (1).

### EPIDEMIOLOGY

## Incidence

- Global incidence of nontyphoidal *Salmonella* enteritidis estimated to be 93.8 million per year in 2009 (2).
  - Wide variation by region from 40 to 3,980 estimated cases per 100,000 in 2009 (2)
- Global incidence of invasive nontyphoidal *Salmonella* infection estimated to be 2.1 to 6.5 million in 2010 (2).
  - Wide variation by region from 0.8 to 227 estimated cases per 100,000 in 2010 (2)
- Most commonly identified foodborne illness in the United States and a common cause of traveler's diarrhea (3)
- Second most common bacteria isolated from stool cultures in diarrheal illness (following *Campylobacter*) in the United States (3)
- Highest incidence in children <5 years old
- Hospitalization rates higher in patients >50 years old
- Peak frequency: July to November

## ETIOLOGY AND PATHOPHYSIOLOGY

- *Salmonella enterica*
  - Most pathogenic species in humans
  - 2,500 different serotypes

## Etiology

- ÷95% of cases are foodborne (3).
- Majority of the other 5% of cases are due to direct or indirect fecal-oral contact with animals or human carriers.
- Iatrogenic contamination (e.g., blood transfusion, endoscopy) is possible, although rare.

## Pathophysiology

- Typical infectious dose in immunocompetent patients is ingestion of one million bacteria (3).
- Bacteria ingested invade the distal ileal and proximal colonic mucosa to produce an inflammatory and cytotoxic response.
- Bacteria can enter the mesenteric lymphatic system and then into systemic circulation to cause

disseminated/invasive disease.

## **RISK FACTORS**

- Recent travel
- Consumption of undercooked meat, egg, or unpasteurized dairy products. Nonanimal products have also been implicated in outbreaks.
- Contact with live reptiles or poultry.
- Contact with human carrier who has *Salmonella* fecal shedding.
- Impaired gastric acidity: H<sub>2</sub> receptor blockers, antacids, proton pump inhibitors (PPIs), gastrectomy, achlorhydria, pernicious anemia, infants
- Recent antibiotic use
- Reticuloendothelial blockade: sickle cell disease, malaria, bartonellosis
- Immunosuppression: HIV, diabetes, corticosteroid or other immunosuppressant use, chemotherapy
- Iron overload, chronic granulomatous disease
- Age <5 years or >50 years

## **GENERAL PREVENTION**

- Proper hygiene in production, transport, and storage of food (e.g., refrigeration during food storage and thoroughly cooking food prior to consumption)
- Control of animal reservoirs: Avoid contact with high-risk animals, animal feces, and polluted waters.
- Hand hygiene
- CDC Web site (<http://www.cdc.gov/salmonella/>) tracks outbreaks

## **COMMONLY ASSOCIATED CONDITIONS**

- Gastroenteritis
- Bacteremia: immunocompromised patients or those with underlying medical conditions (e.g., cholelithiasis, prostheses)
- Osteomyelitis: higher incidence in sickle cell disease
- Abscesses: higher incidence with malignant tumors
- Reactive arthritis

## DIAGNOSIS

### HISTORY

- *Salmonella* infections are typically asymptomatic or result in mild, self-limited gastroenteritis (1)[C].
- Exposure history: travel; contact with infected human, reptile, or poultry; improper food preparation
- Host factors: age, immune status, other risk factors
- Symptoms typically begin 12 to 72 hours after ingestion and resolve within 4 to 10 days (4)[A].
- Acute uncomplicated illness
  - Sudden onset of nausea, vomiting, diarrhea (1)[C]
  - Abdominal cramping (1)[C]
  - Headache (1)[C]
  - Myalgias (1)[C]
  - Fever (1)[C]

### PHYSICAL EXAM

- Fever (1)[A]
- Evidence of hypovolemia (1)[C]
- Abdominal tenderness (1)[C]
- Heme-positive stool in some patients (1)[C]
- Hepatosplenomegaly in some patients (3)[C]

### DIFFERENTIAL DIAGNOSIS

- Viral gastroenteritis
- Bacterial enteritis due to other organisms
- Pseudomembranous colitis
- Inflammatory bowel disease

### DIAGNOSTIC TESTS & INTERPRETATION

## *Initial Tests (lab, imaging)*

- Gastroenteritis
  - Stool culture for *Salmonella*, *Escherichia coli*, *Shigella*, and *Campylobacter* (1)[C]
  - Indications for stool culture include:
    - Severe diarrhea (<sup>3</sup>6 loose stools daily) (1)[C]
    - Diarrhea >1 week in duration (1)[C]
    - Fever (1)[C]
    - Diarrhea containing blood or mucous (1)[C]
    - Multiple cases suggesting an outbreak (1)[C]
  - Fecal leukocytes: positive
- Bacteremia
  - Blood cultures (1)[C]
  - Stool cultures: may also be positive (1)[C]
- Endovascular infection
  - Consider angiography in patients >50 years of age with bacteremia if aortic or vascular source is suspected (4)[A].
- Local infections
  - Wound culture
  - Consider CT or MRI for soft tissue or bone infections (3)[C].
- Chronic carrier state
  - Stool culture positive for > 1 year (3)[C]
  - Urine culture may be positive in chronic carriers.

## *Follow-Up Tests & Special Considerations*

- Diarrhea lasting > 10 days should prompt investigation for other causes.
- Asymptomatic excretion of *Salmonella* may occur for weeks after infection; follow-up fecal cultures are generally not indicated for patients with uncomplicated gastroenteritis (3,4)[C].
- Follow-up blood cultures are suggested for patients with bacteremia (3)[C].

## Test Interpretation

Intestinal biopsies (if taken) may show mucosal ulceration, hemorrhage, and necrosis seen on along with reticuloendothelial hypertrophy/hyperplasia.

## TREATMENT

- Treatment for nonsevere nontyphoidal *Salmonella* gastroenteritis in immunocompetent patients is supportive. The illness is typically self-limited. There is no proven benefit to treatment of mild disease. Treatment can suppress the host immunologic, and higher rates of relapse have been reported (1)[C],(5)[A].
- Consider antibiotics in immunocompetent hosts with severe diarrhea, high fever, or in those requiring hospitalization (1)[C].
- Some patients are at increased risk of bacteremia and benefit from antibiotics:
  - Infants <3 months of age (1)[C]
  - Persons >50 years old especially >65 years old (1,3)[C]
  - Patients with hemoglobinopathies, atherosclerotic lesions, and prosthetic valves, grafts, or joints or any immunosuppressed state (1,3)[C],(4)[A]
- Chronic carriage of nontyphoidal *Salmonella*
  - 4 to 6 weeks of antimicrobial therapy
  - Prophylactic therapy in immunocompromised patients (4)[A]

---

P.937

## GENERAL MEASURES

- Hydration and electrolyte replacement
- Hand washing and barrier precautions for inpatients
- Avoid antimotility drugs in patients with fever or dysentery. Antimotility drugs may increase contact time of the enteropathogen in the gut mucosa (1)[C].

## MEDICATION

### First Line

- Gastroenteritis, uncomplicated: No specific medications are necessary. Supportive care (1)[A]
- Gastroenteritis, complicated (due to illness severity or host risk factors such as

immunocompromise)

- Adults (treat for 14 days if immunocompromised)
  - Levofloxacin (or other fluoroquinolone) 500 mg/day PO for 7 to 10 days (1)[C]; or
  - Trimethoprim-sulfamethoxazole: 160/800 mg PO BID for 7 to 10 days *or*
  - Amoxicillin: 500 mg PO TID for 7 to 10 days *or*
  - Ceftriaxone: 1 to 2 g/day IV for 7 to 10 days *or*
  - Azithromycin: 500 mg/day PO for 7 days (1)[C]
- Children
  - Ceftriaxone: 100 mg/kg/day IV or IM in 2 equally divided doses for 7 to 10 days (1)[C]; *or*
  - Azithromycin: 20 mg/kg/day PO daily for 7 days (1)[C]
- HIV patients
  - Increased duration of antimicrobial therapy and/or zidovudine may decrease relapse (4) [C].
- Bacteremia: Due to resistance trends, treat lifethreatening infections in adults with a fluoroquinolone *and* a 3rd-generation cephalosporin until susceptibilities are determined (4)[A].
  - Adults
    - Ciprofloxacin (or other fluoroquinolone): 400 mg IV BID for 10 to 14 days; *plus*
    - Ceftriaxone: 1 to 2 g/day IV for 10 to 14 days; *or*
    - Cefotaxime: 2 g IV q8h for 10 to 14 days
  - Children
    - Ampicillin: 200 mg/kg/day in 4 divided doses for 10 to 14 days; *or*
    - Trimethoprim-sulfamethoxazole: 8 to 12 mg/kg/day of trimethoprim component in 2 divided doses for 10 to 14 days; *or*
    - Ceftriaxone: 50 to 75 mg/kg/day (max 1 g) once per day for 10 to 14 days
- Localized infection (e.g., septic arthritis, osteomyelitis, cholangitis, and pneumonia)
  - Same treatment as for bacteremia
  - In sustained bacteremia, prolonged local infection, or immunocompromised patients, give antibiotics PO for 4 to 6 weeks (4)[A].

- Chronic carrier state (shedding > 1 year duration)
  - Amoxicillin: 1 g PO TID for 12 weeks; *or*
  - Trimethoprim-sulfamethoxazole 160 mg/800 mg PO BID for 12 weeks; *or*
  - Ciprofloxacin: 500 mg PO BID for 4 weeks, *or*
  - Levofloxacin 500 mg/day for 4 weeks; *or*
  - Norfloxacin 400 mg PO BID for 4 weeks if gallstones are present.

## **ALERT**

### Antimicrobial resistance

- Strains resistant to ampicillin, chloramphenicol, and trimethoprim-sulfamethoxazole have been reported (6)[B].
- Fluoroquinolone resistance is increasing, perhaps due to increasing use in livestock (6)[B].
- Extended-spectrum cephalosporin resistance has been reported with increasing frequency (6) [B].

## *Second Line*

- Aztreonam is an alternative agent that may be useful in patients with multiple allergies or organisms with unusual resistance patterns (4)[A].
- Fluoroquinolones are now routinely given to children for 5 to 7 days in areas of the world where multidrug-resistant *Salmonella typhi* is common (4)[A].

## **SURGERY/OTHER PROCEDURES**

- Surgical excision and drainage for infected tissue sites, followed by a minimum of 2 weeks of antibiotic therapy (4)[A]
- If biliary tract disease is present, a preoperative 10- to 14-day course of parenteral antibiotics is recommended prior to cholecystectomy.

## **ONGOING CARE**

## **FOLLOW-UP RECOMMENDATIONS**

### *Patient Monitoring*

Asymptomatic shedding of *Salmonella* may occur for weeks after infection. Follow-up fecal cultures are generally not indicated for patients with uncomplicated gastroenteritis. Requirements may differ during a *Salmonella* outbreak (4)[A].

- Criteria may vary by state and local regulations. Some public health departments require negative stool cultures for health workers and food handlers prior to returning to work. Shedding may last 4 to 8 weeks (4)[A].
- Serotyping of isolates can be performed at public health laboratories.

## DIET

Easily digestible foods (1)[C]

## PATIENT EDUCATION

- Meticulous hand hygiene; caution handling raw meat, poultry, and eggs
- Fruits and vegetables should be thoroughly washed prior to consumption.
- Thoroughly cooking meats eliminates *Salmonella*.
- Caution when handling animals with high fecal carriage rates
- [www.cdc.gov/salmonella/general/prevention.html](http://www.cdc.gov/salmonella/general/prevention.html)

## PROGNOSIS

- Most cases of *Salmonella* gastroenteritis are selflimited and have an excellent prognosis.
- Increased mortality is seen in the young (<3 months), elderly (>65 years), and immunocompromised (1,2,3).
- Increased mortality is seen with bacteremia and other invasive infections (2,5).
- Mortality is increased in multidrug-resistant strains (5).

## COMPLICATIONS

Toxic megacolon, hypovolemic shock, metastatic abscess formation, endocarditis, infectious endarteritis, meningitis, septic arthritis, reactive arthritis, osteomyelitis, pneumonia, appendicitis, cholecystitis (1,3,4)

Gastroenteritis; Typhoid Fever

**&NA;**

## **ICD10**

- A02.9 Salmonella infection, unspecified
- A02.0 Salmonella enteritis
- A02.1 Salmonella sepsis

## **Clinical Pearls**

**&NA;**

- Nontyphoidal *Salmonella* infection is typically a foodborne infection associated with a self-limited gastroenteritis.
- Clinical syndromes include gastroenteritis, bacteremia, endovascular infection, localized infection outside the GI tract, and a chronic carrier state.
- Those at greatest risk of complications from *Salmonella* infection include the young, the elderly, and immunocompromised patients.
- Uncomplicated gastroenteritis in healthy patients can be treated with supportive care.
- Antibiotics should be used in infants, the elderly, immunocompromised patients, and for invasive infections such as bacteremia outside the GI tract.

# Sarcoidosis

Donnah Mathews, MD, FACP

## BASICS

### DESCRIPTION

- Sarcoidosis is a noninfectious, multisystem granulomatous disease of unknown cause, commonly affecting young and middle-aged adults.
  - Frequently presents with hilar adenopathy, pulmonary infiltrates, ocular and skin lesions
  - In ÷50% of cases, it is diagnosed in asymptomatic patients with abnormal chest x-rays (CXR).
  - Almost any organ may be involved.
- System(s) affected: primarily pulmonary but also cardiovascular, gastrointestinal, hematologic/lymphatic, endocrine, renal, neurologic, dermatologic, ophthalmologic, musculoskeletal
- Synonym(s): Löfgren syndrome (erythema nodosum, hilar adenopathy, fever, arthralgias); Heerfordt syndrome (uveitis, parotid enlargement, facial palsy, fever); Besnier-Boeck disease; Boeck sarcoid; Schaumann disease (1,2,3)[C]

### EPIDEMIOLOGY

#### *Incidence*

Estimated 6/100 person-years (4)

#### *Prevalence*

- Estimated 10 to 20/100,000 persons
- <15% of patients with active disease >60 years of age
- Rare in children (4)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Despite extensive research, mostly unknown

- Thought to be due to exaggerated cell-mediated immune response to unknown antigen(s)
- In the lungs, the initial lesion is CD4+ T-cell alveolitis, causing noncaseating granulomata, which may resolve or may undergo fibrosis.
- Immune paradox with affected organs showing an intense immune response and yet anergy exists elsewhere (1,5)[C].

## Genetics

- Reports of familial clustering, with genetic linkage to a section within MHC on short arm of chromosome 6
- 3 to 4 times more common in African Americans
- Although worldwide in distribution, increased prevalence in Scandinavians, Japanese, African Americans, and women (4)

## RISK FACTORS

Exact etiology and pathogenesis remain unknown.

## GENERAL PREVENTION

None

## COMMONLY ASSOCIATED CONDITIONS

None

## DIAGNOSIS

### HISTORY

- Patients may be asymptomatic.
- Patients may have nonspecific complaints, such as the following:
  - Nonproductive cough
  - Shortness of breath
  - Fever
  - Night sweats
  - Weight loss
  - General fatigue
  - Eye pain

Chest pain/palpitations

- Skin lesions
- Polyarthritits
- Renal calculi
- Facial droop due to Bell palsy
- Encephalopathy, seizures, hydrocephalus (rare)
- Patients >70 years old more likely to have systemic symptoms (5)

## *PHYSICAL EXAM*

- Many patients have a normal physical exam.
- Lungs may reveal wheezing/fine interstitial crackles in advanced disease.
- ÷30% of patients have extrapulmonary manifestations (2), which may include the following:
  - Uveitis
  - Other eye findings: conjunctival nodules, lacrimal gland enlargement, cataracts, glaucoma, papilledema
  - Cranial nerve palsies
  - Salivary gland swelling
  - Lymphadenopathy
  - Arrhythmias
  - Hepatosplenomegaly
  - Polyarthritits
  - Rashes (6)[A]
    - Maculopapular of nares, eyelids, forehead, base of neck at hairline, and previous trauma sites
    - Waxy nodular of face, trunk, and extensor surfaces of extremities
    - Plaques (lupus pernio) of nose, cheeks, chin, and ears
    - Erythema nodosum (component of Lšfgren syndrome)
    - Atypical lesions

## *DIFFERENTIAL DIAGNOSIS*

Infectious granulomatous disease, such as tuberculosis and fungal infections

- Hypersensitivity pneumonitis
- Lymphoma
- Other malignancies associated with lymphadenopathy
- Berylliosis (1)[A]

## ***DIAGNOSTIC TEST & INTERPRETATION***

No definitive test for diagnosis, but diagnosis is suggested by the following:

- Clinical and radiographic manifestations
- Exclusion of other diagnoses
- Histopathologic detection of noncaseating granulomas

### ***Initial Tests (lab, imaging)***

- CBC: Anemia/leukopenia ± eosinophilia can be seen.
- Hypergammaglobulinemia can exist.
- LFTs: Abnormal liver function and increased alkaline phosphatase can be encountered with hepatic involvement.
- Calcium: Hypercalciuria occurs in up to 10% of patients, with hypercalcemia less frequent.
- Serum ACE inhibitors elevated in >75% of patients but is not diagnostic or exclusionary.
  - Drugs may alter lab results: Prednisone will lower serum ACE and normalize gallium scan. ACE inhibitors will lower serum ACE level.
  - Disorders may alter lab results: Hyperthyroidism and diabetes will increase serum ACE level.
- CXR or CT scan may reveal granulomas/hilar adenopathy. Routine CXRs are staged using Scadding classification.
  - Stage 0 = normal
  - Stage 1 = bilateral hilar adenopathy alone
  - Stage 2 = bilateral hilar adenopathy + parenchymal infiltrates
  - Stage 3 = parenchymal infiltrates alone (primarily upper lobes)
  - Stage 4 = pulmonary fibrosis (7)
- Chest CT scan may enhance appreciation of lymph nodes.

- High-resolution chest CT scan may reveal peribronchial disease.
- Gallium scan will be positive in areas of acute disease/inflammation but is not specific.
- Positron emission tomography (PET) scan can indicate areas of disease activity in lungs, lymph nodes, and other areas of the body but does not differentiate between malignancy and sarcoidosis.
- Cardiac PET scan may detect cardiac sarcoidosis (8)[B].

### *Diagnostic Procedures/Other*

- Pulmonary function tests (PFTs) may reveal restrictive pattern with decreased carbon monoxide diffusing capacity (DLCO).
- Characteristically in active disease, bronchioalveolar lavage fluid has an increased CD4-to-CD8 ratio.
- Ophthalmologic examination may reveal uveitis, retinal vasculitis, or conjunctivitis.
- ECG
- Tuberculin skin test
- Biopsy of lesions should reveal noncaseating granulomas.
- If lungs are affected, bronchoscopy with biopsy of central and peripheral airways is helpful. Endobronchial US (EBUS)-guided transbronchial needle aspiration may potentially have a better diagnostic yield.
- Kveim test (ongoing research): suspension of sterilized splenic cells from a patient with sarcoidosis is injected in an intradermal skin test to evoke a sarcoid granulomatous response over 3 weeks, similar to a tuberculin skin test.

### **ALERT**

If signs indicate Löfgren syndrome (acute sarcoid with bilateral hilar lymphadenopathy, erythema nodosum [EN] and diffuse arthritis/arthralgias), it is not necessary to perform a biopsy because prognosis is good with observation alone, and biopsy would not change management.

### *Test Interpretation*

Noncaseating epithelioid granulomas without evidence of fungal/mycobacterial infection

### **TREATMENT**

- Many patients undergo spontaneous remission. It is difficult to assess disease activity and

severity, however, making it challenging to develop guidelines.

- No treatment may be necessary in asymptomatic individuals, but treatment may be needed for specific indications, such as cardiac, CNS, renal, or ocular involvement.
- No treatment is indicated for asymptomatic patients with stage I-III radiographic changes with normal/mildly abnormal lung function, although close follow-up is recommended.

---

P.939

- Treatment of pulmonary and skin manifestations is done on the basis of impairment. The symptoms that necessitate systemic therapy remain controversial.
  - Worsening pulmonary symptoms
  - Deteriorating lung function
  - Worsening radiographic findings

## MEDICATION

Systemic therapy is clearly indicated for hypercalcemia, cardiac disease, neurologic disease, and eye disease not responding to topical therapy. Most patients with pulmonary sarcoidosis do not require treatment with medications, as many are asymptomatic or have a spontaneous remission.

### First Line

- Systemic corticosteroids in the symptomatic individual (dyspnea, cough, hemoptysis) or in the individual with worsening lung function or radiographic findings
  - The optimal dose of glucocorticoids is not known.
  - Usually prednisone initially, 0.3 to 0.6 mg/kg ideal body weight (20 to 40 mg/day) for 4 to 6 weeks.
  - If stable, taper by 5 mg/week to 10 to 20 mg/day over the next 6 weeks.
  - If no relapse, 10 to 20 mg/day for 8 to 12 months
  - Relapse is common.
  - Higher doses (80 to 100 mg/day) may be warranted in patients with acute respiratory failure, cardiac, neurologic, or ocular disease.
- In patients with skin disease, topical steroids may be effective.
- Inhaled steroids (budesonide 800 to 1,600  $\mu$ g BID) may be of some clinical benefit in early disease with mild pulmonary symptoms.
  - Contraindications: patients with known problems with corticosteroids

- Precautions: careful monitoring in patients with diabetes mellitus and/or hypertension
- Significant possible interactions: Refer to the manufacturer's profile of each drug.

## *Second Line*

- All alternative agents to glucocorticoids carry substantial risk for toxicity, including myelosuppression, hepatotoxicity, and opportunistic infection.
- Methotrexate: initially 7.5 mg/week, increasing gradually to 10 to 15 mg/week
- Azathioprine: 50 to 100 mg/day
- Leflunomide: 20 mg/day
- Use of immunosuppressants, such as methotrexate or azathioprine, will require regular monitoring of CBC and LFTs.
- Antimalarial agents, such as chloroquine or hydroxychloroquine
- Tumor necrosis factor antagonists, such as infliximab, have been useful in refractory cases (9) [C].

## *ISSUES FOR REFERRAL*

May be followed by a pulmonologist, with referrals to other specialists as dictated by involvement of other organ systems. If requiring a second-line therapy, should be followed by a specialist.

## *SURGERY/OTHER PROCEDURES*

Lung transplantation in severe, refractory cases; longterm outcomes are unknown.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

None known to be effective

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

There is limited data on indications for the specific tests and optimal frequency of monitoring of disease activity. Suggestions follow.

### *Patient Monitoring*

- Patients on prednisone for symptoms should be seen q1-2mo while on therapy.
- Patients not requiring therapy should be seen regularly (q3mo) for at least the first 2 years

after diagnosis, obtaining a thorough history and physical exam, laboratory testing tailored to sites of disease activity, PFTs, and ambulatory pulse oximetry.

- If active disease
  - Every 6 to 12 months, obtain ophthalmologic exam if on hydroxychloroquine.
  - Annually, CBC, creatinine, calcium, LFTs, ECG, 25-hydroxy vitamin D and 1,25 dihydroxy vitamin D, CXR, ophthalmologic examination
- Other testing per individual patient's symptoms, including HRCT, echocardiogram, Holter monitoring, urinalysis (UA), thyroid-stimulating hormone (TSH), bone density, MRI of brain
- The serum ACE level is used by some physicians to follow the disease activity. In patients with an initially elevated ACE level, it should fall toward normal while on the therapy or when the disease resolves.
- If inactive disease, follow annually with history and physical exam, PFTs, ambulatory pulse oximetry, CBC, creatinine, calcium, liver enzymes, 1,25 dihydroxy vitamin D, EKG, ophthalmologic exam.

## *DIET*

No special diet

## *PATIENT EDUCATION*

- The American Lung Association at [www.lungusa.org/lung-disease/sarcoidosis/?gclid=CPX6zuiipm6MCFQxW2godISFepQ](http://www.lungusa.org/lung-disease/sarcoidosis/?gclid=CPX6zuiipm6MCFQxW2godISFepQ)
- Sarcoidosis by Medline Plus at [www.nlm.nih.gov/medlineplus/sarcoidosis.html](http://www.nlm.nih.gov/medlineplus/sarcoidosis.html)

## *PROGNOSIS*

- 50% of patients will have spontaneous resolution within 2 years.
- 25% of patients will have significant fibrosis, but no further worsening of the disease after 2 years.
- 25% of patients (higher in some populations, including African Americans) will have chronic disease.
- Patients on corticosteroids for >6 months have a greater chance of having chronic disease.
- Overall death rate: <5%

## **COMPLICATIONS**

- Patients may develop significant respiratory involvement, including cor

pulmonale.

- Pulmonary hemorrhage from infection with aspergillosis in the damaged lung is possible.
- Other organs, especially the heart (congestive heart failure, arrhythmias), eyes (rarely blindness), and CNS, can be involved with serious consequences. Cardiac, ocular, and CNS involvement usually manifests early on in patients with these complications of the disease.

## Codes

&NA;

### ICD10

- D86.9 Sarcoidosis, unspecified
- D86.0 Sarcoidosis of lung
- D86.86 Sarcoid arthropathy

## Clinical Pearls

&NA;

- Sarcoidosis is a noninfectious, multisystem granulomatous disease of unknown cause, typically affecting young and middle-aged adults.
- Any organ can be affected.
- Diagnosis is based on clinical findings, exclusion of other disorders, and pathologic detection of noncaseating granulomas.
- Most patients do not need systemic treatment and the disease resolves spontaneously; a few will have life-threatening progressive organ dysfunction.

# Scabies

Kaelen C. Dunican, PharmD

Brandi Hoag, DO

## BASICS

### DESCRIPTION

- A contagious parasitic infection of the skin caused by the mite *Sarcoptes scabiei*, var. *hominis*
- System(s) affected: skin/exocrine
- Synonym(s): sarcoptic mange

### EPIDEMIOLOGY

#### *Incidence*

Predominant age: children and young adults

#### *Prevalence*

- Global prevalence is estimated at 300 million cases per year.
- May be more prevalent in urban areas and areas of overcrowding

### ETIOLOGY AND PATHOPHYSIOLOGY

Itching is a delayed hypersensitivity reaction to the mite saliva, eggs, or excrement.

*S. scabiei*, var. *hominis*

- An obligate human parasite
- Female mite lays eggs in burrows in the stratum corneum and epidermis.
- Primarily transmitted by prolonged human-to-human direct skin contact
- Infrequently transmitted via fomites (e.g., bedding, clothing, or furnishings)

### RISK FACTORS

- Personal skin-to-skin contact (e.g., sexual promiscuity, crowding, nosocomial infection)

- Poor nutritional status, poverty, and homelessness
- Hot, tropical climates
- Seasonal variation: Incidence may be higher in the winter than in the summer (may be due to overcrowding).
- Immunocompromised patients, including those with HIV/AIDS, are at increased risk of developing severe (crusted/Norwegian) scabies.

## GENERAL PREVENTION

Prevent outbreaks by prompt treatment and cleansing of fomites (see "Additional Therapies").

## DIAGNOSIS

### HISTORY

- Generalized itching is often severe and worse at night.
- Determine any contact with infected individuals.
- Initial infection may be asymptomatic.
- Symptoms may develop after 3 to 6 weeks.

## PHYSICAL EXAM

- Lesions (inflammatory, erythematous, pruritic papules) most commonly located in the finger webs, flexor surfaces of the wrists, elbows, axillae, buttocks, genitalia, feet, and ankles
- Burrows (thin, curvy, elevated lines in the upper epidermis that measure 1 to 10 mm in length) may be seen in involved areas—A pathognomic sign of scabies.
- Secondary erosions or excoriations from scratching
- Pustules (if secondarily infected)
- Pruritic nodules in covered areas (buttocks, groin, axillae) resulting from an exaggerated hypersensitivity reaction
- Crusted scabies (Norwegian scabies) is a psoriasiform dermatosis occurring with hyperinfestation with thousands of mites (more common in immunosuppressed patients).

## Geriatric Considerations

The elderly often itch more severely despite fewer cutaneous lesions and are at risk for extensive infestations, perhaps related to a decline in cell-mediated immunity. There may be back involvement in those who are bedridden.

## *Pediatric Considerations*

Infants and very young children often present with vesicles, papules, and pustules and have more widespread involvement, including the hands, palms, feet, soles, body folds, and head (rare for adults).

## ***DIFFERENTIAL DIAGNOSIS***

- Atopic dermatitis
- Contact dermatitis
- Folliculitis/impetigo
- Tinea corporis
- Dermatitis herpetiformis
- Eczema
- Insect bites
- Papular urticaria
- Pediculosis corporis
- Pityriasis rosea
- Prurigo
- Psoriasis (crusted scabies)
- Pyoderma
- Seborrheic dermatitis
- Syphilis

## ***DIAGNOSTIC TEST & INTERPRETATION***

- Definitive diagnosis is based on microscopic identification of mites, eggs, or fecal pellets (scybala) but diagnosis may be based on history and physical exam (1,2,3,4)[C].
- A failure to find mites does not rule out scabies.

## *Initial Tests (lab, imaging)*

CBC is rarely needed but may show eosinophilia.

## *Diagnostic Procedures/Other*

## Examination of skin with magnifying lens

- Look for typical burrows in finger webs and on flexor aspect of the wrists and on the penis.
- Look for a dark point at the end of the burrow (the mite).
- Presumptive diagnosis based on clinical presentation, skin lesions, and identification of burrow (1,2,3).
- Skin scraping
  - Place a drop of mineral oil over a nonexcoriated lesion or burrow.
  - Scrape the lesion with a surgical blade.
  - Examine under a microscope for mites, eggs, egg casings, or feces (1,2)[C].
  - Scraping from under fingernails often may be positive.
  - When mite is not found with scraping, biopsy may reveal mite, eggs, or feces (1,3).
- Potassium hydroxide (KOH) wet mount not recommended because it can dissolve mite pellets.
- Burrow ink test
  - If burrows are not obvious, apply gentian violet or India ink to an area of rash. Wash off the ink with alcohol. A burrow should remain stained and become more evident.
  - Then apply mineral oil, scrape, and observe microscopically, as noted previously (1,3)[C].

## *Test Interpretation*

Skin biopsy of a nodule (although performed rarely) will reveal portions of the mite in the corneal layer.

## **TREATMENT**

### **GENERAL MEASURES**

- Treat all intimate contacts and close household and family members.
- Wash all clothing, bed linens, and towels in hot (60°C) water and dry in hot dryer.
- Personal items that cannot be washed should be sealed in a plastic bag for at least 3 to 5 days.
- Some itching and dermatitis may persist for up to 6 weeks and can be treated with oral antihistamines and/or topical or oral corticosteroids.

# MEDICATION

## First Line

Permethrin 5% cream (Elimite) is generally accepted as first-line therapy (1,2,3,5)[A].

- After bathing or showering, apply cream from the neck to the soles of the feet paying particular attention to areas that are most involved; then wash off after 8 to 14 hours and repeat in 1 week.
- The adult dose is usually 30 g per treatment.
- Side effects include itching and stinging (minimal absorption).
- Crusted scabies may require more frequent application (q2-3d for 1 to 2 weeks) in combination with repeated doses of PO ivermectin on days 1, 2, 8, 9, and 15 (2,3,5)[C].

---

P.941

## Pediatric Considerations

Permethrin may be used on infants >2 months of age. In children <5 years of age, the cream should be applied to the head and neck as well as to the entire body.

## Second Line

- Ivermectin (Stromectol)
  - Not FDA approved for scabies
  - 200 to 250  $\mu$ g/kg PO as single dose; repeated in 1 week
  - Take with food to improve bioavailability and enhance penetration into the epidermis.
  - May need higher doses or may need to use in combination with topical scabicide for HIVpositive patients
- Crotamiton (Eurax) 10% cream
  - Apply from the neck down for 24 hours, rinse off, then reapply for an additional 24 hours, and then thoroughly wash off.
  - Nodular scabies: Apply to nodules for 24 hours, rinse off, reapply for an additional 24 hours, then thoroughly wash off.
- Precipitated sulfur 2-10% in petrolatum
  - Not FDA approved for scabies
  - Apply to the entire body from the neck down for 24 hours, rinse by bathing, then repeat for 2 more days (3 days total). It is malodorous and messy but is thought to be safer than

lindane, especially in infants <6 months of age, and safer than permethrin in infants <2 months of age.

- Lindane (&agr;-benzene hexachloride, Kwell) 1% lotion
  - Apply to all skin surfaces from the neck down and wash off 6 to 8 hours later.
  - Two applications 1 week apart are recommended but may increase the risk of toxicity.
  - 2 oz is usually adequate for an adult.
    - Side effects: neurotoxicity (seizures, muscle spasms), aplastic anemia
    - Contraindications: uncontrolled seizure disorder, premature infants
    - Precautions: Do not use on excoriated skin, on immunocompromised patients, in conditions that may increase risk of seizures, or with medications that decrease seizure threshold.
    - Possible interactions: concomitant use with medications that lower the seizure threshold

## **ALERT**

Lindane: FDA black box warning of severe neurologic toxicity; use only when all other agents have failed.

### *Pediatric Considerations*

- The FDA recommends caution when using lindane in patients who weigh <50 kg. It is not recommended for infants and is contraindicated in premature infants.
- PO ivermectin should be avoided in children <5 years and in those weighing <15 kg.

### *Pregnancy Considerations*

- Permethrin is pregnancy Category B, and lindane, ivermectin, and crotamiton are Category C.
- Permethrin is considered compatible with lactation, but if permethrin is used while breastfeeding, the infant should be bottlefed until the cream has been thoroughly washed off.

## **ADDITIONAL THERAPIES**

- Crusted scabies may require use of keratolytics to improve penetration of permethrin.
- Benzyl benzoate lotion (not available in the United States but used widely in developing countries)
  - Not FDA approved for scabies.

Dose for adults is 25-28%; dilute to 12.5% for children and 6.25% for infants

- After bathing, apply lotion from the neck to soles of feet for 24 hours.
- Topical ivermectin 1% lotion (investigational, not available for use in the United States) (4)
  - Not FDA approved for scabies.
  - Apply to affected sites and wash off 8 hours later.

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

Herbal products such as tea tree oil, clove oil, neem oil, and aloe vera require additional evidence to establish efficacy (4).

## **ONGOING CARE**

### **FOLLOW-UP RECOMMENDATIONS**

#### ***Patient Monitoring***

Recheck patient at weekly intervals only if rash or itching persists. Scrape new lesions and retreat if mites or products are found.

### **PATIENT EDUCATION**

- Patients should be instructed on proper application and cautioned not to overuse the medication when applying it to the skin.
- A patient fact sheet is available from the CDC: <http://www.cdc.gov/parasites/scabies/>

### **PROGNOSIS**

- Lesions begin to regress in 1 to 2 days, along with the worst itching, but eczema and itching may persist for up to 6 weeks after treatment.
- Nodular lesions may persist for several weeks, perhaps necessitating intralesional or systemic steroids.
- Some instances of lindane-resistant scabies have now been reported. These cases do respond to permethrin.

### **COMPLICATIONS**

- Poor sleep due to pruritus
- Social stigma

- Secondary bacterial infection (group A streptococci and *Staphylococcus aureus*)
- Sepsis
- Glomerulonephritis
- Eczema
- Pyoderma
- Postscabetic pruritus
- Nodules (nodular scabies) may persist for weeks to months after treatment.

## ICD10

B86 Scabies

# Clinical Pearls

## &NA;

- Prior to diagnosis, use of a topical steroid to treat pruritic symptoms may mask symptoms and is termed *scabies incognito*.
- Environmental control is recommended. All linens, towels, and clothing used in the previous 4 days should be washed in hot water or dry-cleaned. Personal items that cannot be washed or dry-cleaned should be sealed in a plastic bag for 3 to 5 days.
- All members of the affected household may require treatment, especially close contacts (those sharing the same bed or who have intimate contact).
- Eczema and itching may persist for up to 6 weeks after treatment, causing many patients to falsely believe that they have failed treatment or are being reinfected.
- In patients with actual reinfection, either the patient has not applied the medication properly or, more likely, the index patient has not been identified and treated.

# Scarlet Fever

John C. Huscher, MD

## BASICS

### DESCRIPTION

- A disease (typically in childhood) characterized by fever, pharyngitis, and rash caused by group A *β*-hemolytic *Streptococcus pyogenes* (GAS) that produces erythrogenic toxin
- Incubation period: 1 to 7 days
- Duration of illness: 4 to 10 days
- Rash usually appears on the second day of illness.
- Rash first appears on the upper chest and flexural creases and then spreads rapidly all over the body.
- Rash clears at the end of the 1st week and is followed by several weeks of desquamation.
- System(s) affected: head, eyes, ears, nose, throat, skin/exocrine
- Synonym(s): scarlatina

### EPIDEMIOLOGY

#### Incidence

- Rare in infancy because of maternal antitoxin antibodies
- Predominant age: 6 to 12 years
- Peak age: 4 to 8 years
- Predominant sex: male = female
- Rare in the United States in persons > 12 years because of high rates (>80%) of lifelong protective antibodies to erythrogenic toxins
- Increased rates are noted in United Kingdom in 2013.

#### Prevalence

- 5-30% of cases of pharyngitis in children are due to GAS.

- <10% of children with streptococcal pharyngitis develop scarlet fever.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Erythrogenic toxin production is necessary to develop scarlet fever.
- Three toxin types: A, B, C
- Toxins damage capillaries (producing rash) and act as superantigens, stimulating cytokine release.
- Antibodies to toxins prevent development of rash but do not protect against underlying infection.
- Primary site of streptococcal infection is usually within the tonsils, but scarlet fever may also occur with infection of skin, surgical wounds, or uterus (puerperal scarlet fever).

## *RISK FACTORS*

- Winter/spring seasonal increase
- More common in school-aged children
- Contact with infected individual(s)
- Crowded living conditions (e.g., lower socioeconomic status, barracks, child care, schools)

## *GENERAL PREVENTION*

- Spread by contact with airborne respiratory droplets
- Asymptomatic contacts do not require cultures/prophylaxis.
- Symptomatic contacts may be treated with or without culture.
- Children should not return to school/daycare until they have received 24 hours of antibiotic therapy.

## *COMMONLY ASSOCIATED CONDITIONS*

- Pharyngitis
- Impetigo
- Rheumatic fever
- Glomerulonephritis

# DIAGNOSIS

## HISTORY

Prodrome 1 to 2 days

- Sore throat
- Headache
- Myalgias
- Malaise
- Fever ( $>38^{\circ}\text{C}$  [ $100.4^{\circ}\text{F}$ ])
- Vomiting
- Abdominal pain (may mimic acute abdomen)
- Rash—scarlatiniform erythematous punctate eruption
- Cough, conjunctivitis, hoarseness, and rhinorrhea are more commonly associated with viral infections.

## PHYSICAL EXAM

- Oral exam
  - Beefy red tonsils and pharynx with/without exudate
  - Petechiae on palate
  - White coating on tongue: White strawberry tongue appears on days 1 to 2. This sheds by days 4 to 5, leaving a red strawberry tongue, which is shiny and erythematous with prominent papillae.
- Exanthem (appears within 1 to 5 days)
  - Scarlet macules with generalized erythema; blanches when pressed
  - Orange-red punctate skin eruption with sandpaperlike texture, sunburn with goose pimples
  - Coarse sandpaper rash—helpful in darkskinned individuals
  - Initially, rash appears on chest and axillae. It then spreads to abdomen and extremities; prominent in skin folds, flexural surfaces (e.g., axillae, groin, buttocks), with sparing of palms and soles.
  - Flushed face with circumoral pallor, red lips
  - Pastia lines: transverse red streaks in skin folds of abdomen, antecubital space, and axillae

- Desquamation begins on face after 7 to 10 days and proceeds over trunk to hands and feet; may persist for 6 weeks.
- In severe cases, small vesicular lesions (miliary sudamina) may appear on abdomen, hands, and feet.

## ***DIFFERENTIAL DIAGNOSIS***

- Viral exanthem: measles; rubella; roseola
- Infectious mononucleosis
- *Mycoplasma pneumonia*
- Secondary syphilis
- Toxic shock syndrome
- Staphylococcal scalded-skin syndrome
- Kawasaki disease
- Drug hypersensitivity
- Severe sunburn

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Test for GAS pharyngitis by rapid antigen detection test (RADT) and/or culture with pharyngeal swab because clinical features alone do not reliably discriminate between GAS and viral pharyngitis.
- Testing for GAS pharyngitis is *not recommended* for patients with symptoms suggesting a viral etiology (e.g., cough, rhinorrhea, hoarseness, oral ulcers).

### ***Initial Tests (lab, imaging)***

- RADT: diagnostic if positive, 95% specific; sensitivity approaches that of culture. Negative RADT should be confirmed by throat culture. Positive RADTs do not require backup culture (1) [C].
- Throat culture: *&bgr*;-hemolytic colonies that are catalase negative and sensitive to bacitracin; culture is the gold standard for confirming streptococcal infection (99% specific, 90-97% sensitive; 5-10% of healthy individuals are carriers) (1).
- Serologic tests (antistreptolysin O titer and streptozyme tests, antihyaluronidase): Confirm recent GAS infection; not helpful or recommended for diagnosis of acute disease.
- Gram stain: gram-positive cocci in chains

- CBC may show elevated WBC count (12,000 to 16,000/mm<sup>3</sup>); eosinophilia later (second week).
- Follow-up (posttreatment) throat cultures or RADT not routinely recommended
- Diagnostic testing and empiric treatment of asymptomatic household contacts of patients with acute streptococcal pharyngitis is not routinely recommended (2)[B].
- Appropriately symptomatic patients >3 years old with a family member recently diagnosed with laboratory-confirmed GAS pharyngitis may be treated without screening or confirmatory testing (3)[C].

### *Follow-Up Tests & Special Considerations*

- Recent antibiotic therapy may impact culture results.
- Within 5 days of symptoms, antibiotics can delay/abolish antistreptolysin O response.

### *Test Interpretation*

Skin lesions reveal characteristic inflammatory reaction, specifically hyperemia, edema, and polymorphonuclear cell infiltration.

## **TREATMENT**

### *GENERAL MEASURES*

Supportive care; analgesic/antipyretic such as acetaminophen or an NSAID, for treatment of moderate to severe symptoms or control of fever

P.943

### *MEDICATION*

#### *First Line*

The main reason for treating GAS is to decrease the risk of acute rheumatic fever. Early treatment decreases duration of symptoms by 1 to 2 days and decreases the period of contagiousness (3) [B].

- Penicillin (PO; penicillin V and others) for 10 days
  - 250 mg PO BID or TID for <sup>3</sup>27 kg (60 lb); 500 mg BID or TID for >27 kg (60 lb) adolescents and adults(1,4,5)[A]
  - If compliance is questionable, use penicillin G, benzathine: single IM dose 600,000 U for <sup>3</sup>27 kg (60 lb); 1.2 mU for those >27 kg.

- Amoxicillin (PO) 50 mg/kg once daily or 25 mg/kg twice daily for 10 days (use only for definitive GAS because it can induce rash with some viral infections) (6)[A]
  - Contraindications: penicillin allergy
- Acetaminophen for fever and pain
- Precautions: Avoid in patients with penicillin allergy (anaphylaxis).

## *Second Line*

- For patients allergic to penicillin
  - Azithromycin (Zithromax, Z pack): 12 mg/kg/day (max 500 mg) for 5 days (4)[A]
  - Clarithromycin (Biaxin): children >6 months: 7.5 mg/kg BID for 10 days; adults: 250 mg BID for 10 days
- Oral cephalosporins: Many are effective, but firstgeneration cephalosporins are less expensive:
  - Cephalexin 25 to 50 mg/kg/day divided every 12 hours for 10 days; max 500 mg every 12 hours (1)[A]
  - Cefadroxil 30 mg/kg/day divided BID; max 500 mg BID for 10 days (1)
- Clindamycin 20 mg/kg/day divided TID for 10 days (4)[B]
- Tetracyclines and sulfonamides should not be used.

### **ALERT**

Avoid aspirin in children due to risk of Reye syndrome.

## *ISSUES FOR REFERRAL*

Peritonsillar abscess; shock symptoms: hypotension, disseminated intravascular coagulation (DIC), cardiac, liver, renal dysfunction

## *SURGERY/OTHER PROCEDURES*

- Tonsillectomy is recommended with recurrent bouts of pharyngitis (<sup>36</sup> positive strep cultures in 1 year).
- While children still may get streptococcal pharyngitis (Òstrep throatÓ) after a tonsillectomy, the procedure reduces the frequency and severity of infections.

**ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

Follow-up throat culture is not needed unless the patient is symptomatic.

### ***Patient Monitoring***

GAS is uniformly susceptible to penicillin, treatment failures are typically due to:

- Poor adherence to recommended antibiotic therapy
- *β*-Lactamase oral flora hydrolyzing penicillin
- GAS carrier state and concurrent viral rash (requires no treatment)
- Repeat exposure to carriers in family: Streptococci persist on nonrinsed toothbrushes and orthodontic appliances for up to 15 days.
- Recurrent GAS pharyngitis after a recent oral antibiotic course can be retreated with the same agent, an alternative oral agent, or IM penicillin G.

### ***DIET***

No special diet

## ***PATIENT EDUCATION***

- A brief delay in initiating treatment awaiting culture results does not increase the risk of rheumatic fever.
- Complete the entire course of antibiotics.
- Children should not return to school/daycare until they have received >24 hours of antibiotic therapy.
- Can spread person to person: attend to personal hygiene (wash hands, don't share utensils)
- Recurring strep throat: When is tonsillectomy useful?  
(<http://www.mayoclinic.org/diseasesconditions/strep-throat/expert-answers/recurringstrep-throat/faq-20058360>)

## ***PROGNOSIS***

- Symptoms are shortened by 12 to 24 hours with penicillin.
- Recurrent attacks are possible (different erythrogenic toxins).

## **COMPLICATIONS**

- Suppurative
  - Sinusitis

- Otitis media/mastoiditis
- Cervical adenitis
- Peritonsillar abscess/retropharyngeal abscess
- Pneumonia
- Bacteremia with metastatic infectious foci: meningitis, brain abscess, osteomyelitis, septic arthritis, endocarditis, intracranial venous sinus thrombosis, necrotizing fasciitis
- Nonsuppurative
  - Rheumatic fever: Therapy prevents rheumatic fever when started as long as 10 days after onset of acute GAS infection.
  - Glomerulonephritis: due to nephritogenic strain of *Streptococcus*; prevention even after adequate treatment of GAS is less certain
  - Streptococcal toxic shock syndrome: fever; hypotension; DIC; and cardiac, liver, and/or kidney dysfunction related to other toxin-mediated sequelae
  - Cellulitis
  - Weeks to months later, may develop transverse grooves in nail plates and hair loss (telogen effluvium)

## See Also

**&NA;**

- Pharyngitis
- Algorithm: Pharyngitis

## Codes

**&NA;**

### ICD10

- A38.9 Scarlet fever, uncomplicated
- J02.0 Streptococcal pharyngitis
- A38.0 Scarlet fever with otitis media

## Clinical Pearls

**&NA;**

- Consider scarlet fever in the differential diagnosis of children with fever and an exanthematous rash.
- Key clinical findings include strawberry tongue, circumoral pallor, and a coarse sandpaper rash.
- Desquamation (7 to 10 days after symptom onset) may last for several weeks following acute illness in scarlet fever.
- Throat culture remains the diagnostic test of choice to document streptococcal illness.
- Penicillin is the drug of choice for treatment.

# Schizophrenia

Maja Skikic, MD

Jeffrey G. Stovall, MD

## BASICS

Schizophrenia is a chronic, severe, and disabling psychiatric condition characterized by neurocognitive changes and impairment in reality testing.

### DESCRIPTION

- Major psychiatric disorder characterized by prodrome, active, and residual psychotic symptoms involving disturbances in appearance, speech, behavior, perception, and thought that last for at least 6 months.
- DSM-5 has eliminated subcategories of schizophrenia (1).
- System(s) affected: central nervous system

### EPIDEMIOLOGY

#### *Incidence*

- 7.7 to 43/100,000 (2)
- Predominant sex: male-to-female ratio = 1.4:1.0
- Age of onset: typically <30 years, earlier in males (early to mid-20s) than females (late 20s), with a smaller peak that occurs in women >45 years (3)

#### *Prevalence*

- Lifetime (1%): highest prevalence in lower socioeconomic classes and urban settings (2-fold higher risk) (2)
- 1.1% of the population > 18 years old; similar rates in all countries

### ETIOLOGY AND PATHOPHYSIOLOGY

- Stems from a complex interaction between genetic and environmental factors; higher incidence if prenatal infection or hypoxia, winter births, first-generation immigrants, advanced paternal age, drug use, and genetic (velocardiofacial) syndromes

- Overstimulation of mesolimbic dopamine D<sub>2</sub> receptors, deficient prefrontal dopamine, and aberrant prefrontal glutamate (NMDA) activity results in perceptual disturbances, disordered thought process, and cognitive impairments (4).

## *Genetics*

If first-degree biologic relative has schizophrenia, risk is 8-10%; a 10-fold increase (5).

## **GENERAL PREVENTION**

- Currently, no known preventive measures decrease the incidence of schizophrenia.
- Interventions to improve long-term outcome and associated comorbid conditions are employed during management.

## **COMMONLY ASSOCIATED CONDITIONS**

- Substance use disorders and nicotine dependence are common and lead to significant long-term medical and social complications (6).
- Metabolic syndrome, diabetes mellitus, obesity, and certain infectious diseases, including HIV, hepatitis B, and hepatitis C all occur in higher-than-expected rates in individuals with schizophrenia.

## **DIAGNOSIS**

Focus on identifying an insidious social and functional decline per history with the onset of <sup>32</sup> of the following characteristic symptoms on mental status exam:

- Delusions (fixed, false beliefs)
- Hallucinations (auditory > visual perceptual disturbances)
- Disorganized thought (derailed or incoherent speech)
- Grossly disorganized/catatonic behavior (hyper- or hypoactive movements that are often repetitive)
- Negative symptoms (affective flattening, amotivation, avolition, asociality) (1)

## **PHYSICAL EXAM**

No physical findings characterize the illness; however, chronic treatment with neuroleptic agents may result in parkinsonism, tardive dyskinesia, and other extrapyramidal symptoms.

# *DIFFERENTIAL DIAGNOSIS*

- Psychotic disorder due to another medical condition
  - Disorientation, in particular, indicates delirium.
  - Possible medical illnesses include porphyria, TBI, infection, tumor, metabolic, endocrine, and intoxication, including withdrawal states and disorders that affect the CNS (i.e., epilepsy, Huntington disease, Wilson disease, lupus cerebritis, anti-NMDA limbic encephalitis, metachromatic leukodystrophy).
- Substance-induced psychosis: secondary to substance use/abuse, such as cocaine, hallucinogens (amphetamines, LSD, phencyclidine), cannabis (including synthetic), bath salts, alcohol, or prescribed medications including steroids, anticholinergics, and opiates
- Personality disorders (paranoid, schizotypal, schizoid, borderline personality disorder)
- Mood disorders: bipolar disorder, major depressive disorders with psychotic features, or schizoaffective disorder
- Delusional disorder
- Posttraumatic stress disorder
- Cultural belief system

# *DIAGNOSTIC TESTS & INTERPRETATION*

- No tests are available to indicate schizophrenia.
- Imaging and laboratory tests are needed to rule out other causes.

## *Initial Tests (lab, imaging)*

These are needed to rule out a medical etiology of psychotic symptoms and when starting antipsychotic medications; these may include the following:

- Brain MRI, EEG, LP (as clinically indicated)
- CBC, blood chemistries
- Thyroid-stimulating hormone (TSH)
- Blood glucose level, preferably fasting
- Hemoglobin A1C
- Fasting lipid panel
- Vitamin levels (thiamine, vitamin D, B<sub>12</sub>)

- Drug/alcohol screen of blood and urine
- Urinalysis
- Urine pregnancy test
- Rapid plasma reagin (RPR), HIV
- Heavy-metal exposure: lead, mercury
- Ceruloplasmin, urine porphobilinogen as indicated
- ECG, for baseline QTc

### *Follow-Up Tests & Special Considerations*

Clinical and laboratory tests for routine monitoring, at least yearly, if using antipsychotic medications (7)[A]

- Blood pressure, weight, and waist circumference
- CBC, blood chemistries
- Fasting blood glucose level, hemoglobin A1C
- Lipid panel
- TSH
- Pregnancy test and prolactin level, if indicated
- ECG, monitoring for QTc prolongation

### *Diagnostic Procedures/Other*

- Psychological: not a routine part of assessment
- MRI and EEG to rule out seizure/neurologic disorder
- Lumbar puncture if indicated by clinical presentation

### *Test Interpretation*

No diagnostic pathologic findings; however, ventriculomegaly is frequently seen on MRI with whole brain grey matter loss and white matter loss in medial temporal lobe structures preferentially (8)[A].

## **TREATMENT**

# MEDICATION

## First Line

- Two classes of antipsychotic medications: typical and atypical. First-line treatment is with an atypical antipsychotic given lower potential for extrapyramidal side effects.
  - Atypical (2nd generation)
    - Risperidone, olanzapine, ziprasidone, aripiprazole, quetiapine, paliperidone, iloperidone, asenapine, lurasidone, clozapine
  - Typical (1st generation)
    - Haloperidol, chlorpromazine, fluphenazine, trifluoperazine, perphenazine, thioridazine, thiothixene, loxapine
- Medication choice is based on clinical and subjective response and side effect profile (7)[A].
- Sensitivity to extrapyramidal adverse effects: atypical
- For least risk of tardive dyskinesia: quetiapine, clozapine
- For least risk of metabolic syndrome: aripiprazole, ziprasidone, lurasidone
- For poor compliance/high risk of relapse: injectable form of long-acting antipsychotic such as haloperidol, fluphenazine, risperidone, olanzapine, aripiprazole, or paliperidone
- Usual oral daily dose (initial dose may be lower)
  - Chlorpromazine: 200 mg BID
  - Aripiprazole: 10 to 30 mg/day
  - Asenapine: 5 mg BID (sublingual)
  - Fluphenazine: 5 mg BID
  - Haloperidol: 5 mg BID
  - Lurasidone: 40 to 80 mg/day
  - Olanzapine: 15 to 30 mg/day
  - Paliperidone: 3 to 12 mg/day
  - Perphenazine: 24 mg/day divided BID or TID
  - Quetiapine: 200 to 300 mg BID
  - Risperidone: 3 mg/day
  - Ziprasidone: 60 to 80 mg BID (with meal)

- Clozapine: 200 mg BID
  - Start 12.5 mg/day and increase daily by 25 mg until dose of 300 mg/day split into BID dosing; do not exceed 900 mg/day. Effective in treatment of refractory or suicidal patients (7)[A]
  - Serious risk of agranulocytosis mandates registration with National Clozapine Registry and monitoring regular periodic CBC with differential (weekly to once monthly).
  - Significant risk of seizure at higher doses
  - Side effects can include myocarditis, DVT, sialorrhea, tachycardia, and weight gain.

## **ALERT**

All antipsychotics are associated with weight gain and carry the risk of metabolic SE and tardive dyskinesia.

P.945

- Managing adverse effects of antipsychotics
  - Dystonic reaction (especially of head and neck): Give diphenhydramine 25 to 50 mg IM or benztropine 1 to 2 mg IM.
  - Akathisia: propranolol 10 mg BID or lorazepam 0.5 mg BID
  - Pseudoparkinsonism: trihexyphenidyl 2 mg BID (may be increased to 15 mg/day if needed) or benztropine 0.5 BID (range 1 to 4 mg/day)
  - Akathisia (restlessness): propranolol (30 to 60 mg in divided doses) or lorazepam (range 1 to 2 mg/day)
  - Neuroleptic malignant syndrome: hyperthermia, autonomic dysfunction, and extrapyramidal symptoms; requires hospitalization and supportive management (IVF and cessation of offending neuroleptic)
- Geriatric considerations: All antipsychotics carry a black box warning for increased mortality risk in elderly dementia patients.
- Adjunctive treatments
  - Benzodiazepines
    - May be effective adjuncts to antipsychotics during acute phase of illness
    - Useful for the treatment of catatonia
    - Withdrawal reactions with psychosis or seizures

Mood stabilizers (valproic acid, lithium, lamotrigine, carbamazepine): may be effective adjuncts for those with agitated/violent behavior (7,9)[A]

- Antidepressants: if prominent symptoms of depression are present
- Metformin: helps minimize risk of metabolic SE with use of AP (10)[A]

## *ISSUES FOR REFERRAL*

- Consider in cases of suicidality, coexistence of an addiction, difficulty in engagement, or poor self-care.
- Patients with schizophrenia should receive multidisciplinary care from both a primary care physician and a psychiatrist.
- Family members often benefit from referral to family advocacy organizations such as NAMI (11)[A].

## *ADDITIONAL THERAPIES*

Family and patient education and psychotherapy. These include specific treatments to reduce the impact of psychotic symptoms and to enhance social functioning. Cognitive-behavioral therapy has been shown to be effective for specific symptoms of schizophrenia (12)[C].

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

No alternative therapies are validated.

## *SURGERY/OTHER PROCEDURES*

- Electroconvulsive therapy (ECT): For patients presenting with catatonic features, the option of ECT should be considered early when insufficient response to benzodiazepines is observed (7) [B].
- Surgical interventions are not available.

## *INPATIENT CONSIDERATIONS*

Initial stabilization focuses on maintaining a safe environment and reducing acute psychotic symptoms and agitation through the initiation of pharmacologic treatment.

### *Admission Criteria/Initial Stabilization*

The decision to admit is usually based on the patient's risk of self-harm or harm to others and the inability to care for self as governed by local legal statute.

### *Nursing*

Monitor for safety concerns and establish a safe and supportive environment.

## *Discharge Criteria*

Based on the patient's ability to remain safe in the community. It reflects a combination of suicide risk, level of psychotic symptoms, support systems, and the availability of appropriate outpatient services.

**ONGONG CARE**

## *FOLLOW-UP RECOMMENDATIONS*

- Long-term symptom management and rehabilitation depend on engagement in ongoing pharmacologic and psychosocial treatment.
- Monitoring is based on evaluation of symptoms (including safety and psychotic symptoms), looking for the emergence of comorbidities, medication side effects, and prevention of complications.

## *DIET*

- Newer atypical antipsychotics confer a higher risk of metabolic side effects such as diabetes, hypercholesterolemia, and weight gain.
- Although there are no specific dietary requirements, attention should be paid to the high risk of development of obesity and metabolic syndrome in individuals with schizophrenia.

## *PATIENT EDUCATION*

- National Institute of Mental Health: *Schizophrenia*, at [www.nimh.nih.gov/health/topics/schizophrenia/index.shtml](http://www.nimh.nih.gov/health/topics/schizophrenia/index.shtml)
- *Helping a Family Member with Schizophrenia*: [www.aafp.org/afp/20070615/1830ph.html](http://www.aafp.org/afp/20070615/1830ph.html)
- National Alliance on Mental Illness (NAMI): [www.NAMI.org](http://www.NAMI.org)

## *PROGNOSIS*

- Typical course is one of remissions and exacerbations. Although uncommon, there are known cases of complete remission and of refractory illness
- Negative symptoms are often most difficult to treat.
- Excessive mortality occurs due to suicide, accidents, coronary artery disease, pulmonary disease, or substance use disorders; guarded prognosis

## COMPLICATIONS

- Side effects from antipsychotic medications including tardive dyskinesia, orthostatic hypotension, QTc prolongation, and metabolic syndrome
- Self-inflicted trauma and suicide
- Combative behavior toward others
- Comorbid addictions, including nicotine (13)[A]

## Codes

&NA;

### ICD10

- F20.9 Schizophrenia, unspecified
- F20.0 Paranoid schizophrenia
- F20.1 Disorganized schizophrenia

# Clinical Pearls

**&NA;**

- A debilitating chronic mental illness that affects all cultures
- Schizophrenia is characterized by positive symptoms, including hallucinations such as voices that converse with/about the patient, delusions that are often paranoid, and negative symptoms, including flattened affect, loss of a sense of pleasure, loss of will/drive, and social withdrawal.
- Multidisciplinary teams to enhance patient and family coping with serious and persistent mental illness, to prevent and treat comorbidities, and to promote recovery

# Sciwora Syndrome (Spinal Cord Injury Without Radiologic Abnormality)

Patrick M. Carey, DO

Jason B. Alisangco, DO, FAAFP

## BASICS

Also called spinal cord injury without radiographic evidence of trauma (SCIWORET), spinal cord injury without CT evidence of trauma (SCIWOCTET), or spinal cord injury without neuroimaging abnormality (SCIWONA)

## DESCRIPTION

- SCIWORA occurs after trauma; it is an acute spinal cord injury (SCI) and nerve root trauma resulting in transient or permanent sensory, motor, or combined sensorimotor deficits.
- Neural injuries occur without a fracture or misalignment visible on radiographic imaging (x-ray, CT).
- SCIWORA has a broad presentation, from minor neurologic symptoms to complete quadriplegia.

## EPIDEMIOLOGY

### Incidence

- Variable: reported to be 19-34% of pediatric spinal cord injuries (1)
- Occurs in all populations but is primarily observed in pediatric patients (90%) (1)
- Bimodal: affects children <8 years old and adults >60 years old; rarely occurs between 16 and 36 years (2)
- There is no association between Chiari malformation type 1 and SCIWORA.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Trauma (3)
  - Motor vehicle collision (MVC) (most common cause); either unrestrained passengers, pedestrians, or bicyclists struck by motor vehicles

- Sports-related injury
- Significant fall
- Child abuse
- Mechanism
  - Traumatic neural (edema, hematomyelia, cord disruption) and extraneural (disc injury or ligament disruption) injury occurs after (2,4,5) the following:
    - Hyperextension
    - Hyperflexion
    - Longitudinal distraction
    - Ischemic damage
    - Secondary injury from inflammatory response to tissue damage
- Age: Pediatric patients have a higher incidence of SCIWORA than adults due to anatomic differences and increased mobility and flexibility (1,4,6).
  - Horizontally oriented facet joints permit more translational motion in the coronal (AP) plane.
  - Anterior wedging of vertebral bodies
  - Elasticity of ligaments and joint capsules permits increased intersegmental movement and disc protrusion.
  - In patients age <8 years, head size-to-trunk ratio is disproportionately large.
  - Weaker nuchal musculature
  - Uncovertebral joints are absent.
  - Pseudosubluxation of C2 to C3
- Location
  - Cervical: upper > lower
  - Thoracic: protected and splinted by ribs, preventing forced flexion and extension
  - Lumbar: rare, usually fatal (1)

## *RISK FACTORS*

- History of trauma
- Age <8 years

- Male: female
  - Adult; 4.5:1 (3,7), Children; 2:1 (3)
- Improper wear of seatbelt

## DIAGNOSIS

### HISTORY

- MVA
- Sports-related injury
- Fall
- Child abuse

### PHYSICAL EXAM

- Assess for sensorimotor deficit.
- Abnormal neurologic findings are not accounted for by known/visible injuries.
- Abnormalities on musculoskeletal exam increases risk of SCI.

### DIFFERENTIAL DIAGNOSIS

- End-plate cartilage fracture
- Transverse myelitis
- Intramedullary hemorrhage
- Anterior spinal artery syndrome
- Disseminated encephalomyelitis
- Atlantoaxial dislocation
- Central cord syndrome
- Brown-Sequard syndrome

### DIAGNOSTIC TESTS & INTERPRETATION

- Radiographic screening with CT of the entire spinal column is recommended (5)[C].
- MRI of the region of suspected neurologic injury (5)[C]
- MRI within 24 hours of injury and consider repeat if normal (7)[C]

- Assessment of spinal stability in a SCIWORA patient is recommended with flexion-extension radiographs in the acute setting and at late follow-up, even in the presence of a magnetic resonance imaging (MRI) negative for extraneural injury (5)[C].
- Neither spinal angiography nor myelography is recommended in the evaluation of patients with SCIWORA (5)[C].
- CT scan can reliably rule out fracture.

## Follow-Up Tests & Special Considerations

- Adult considerations: Adults are less prone to SCIWORA due to decreased flexibility and mobility in comparison to pediatric patients, although SCIWORA is possible in the setting of acute trauma or cervical spondylosis.
- A normal MRI does not rule out SCIWORA (1,2,7).
- MRI abnormalities correlate closely with neurologic injury and prognosis (3)[C].
- MRI may be able to demonstrate neural and extraneural injuries: cartilaginous end-plate fracture, edema, herniation, and interspinous ligamentous injury (1,2)

## Diagnostic Procedures/Other

- Diagnosis is based on clinical findings of neurologic dysfunction or MRI abnormality.
- Consider diffusion-weighted MRI and somatosensoryevoked potentials (SSEPs) in cases of suspected SCIWORA with normal MRI (5,8)[C].

## TREATMENT

### GENERAL MEASURES

- Immobilize unconscious patients until plain x-ray and CT radiographs are obtained.
- Immobilize until neurologic and pain assessment can be made.
- Transient findings, such as numbness, and a history of trauma should be treated with immobilization following SCI protocol.
- Supportive care and serial neurologic and musculoskeletal exams
- Blood pressure support (5)[C]
- Corticosteroid use is controversial and is not considered standard practice for pediatric cases (6)[C].

## ADDITIONAL THERAPIES

- Rigid external immobilization of the spinal segment for 12 weeks (day and night) (1)
- Immobilization for 12 weeks even after the return of normal neurologic function to minimize SCIWORA recurrence (1,2,5)[C]
- Avoidance of "high-risk" activities for up to 6 months following SCIWORA (2,5)[C]
- Initially, treatment is nonoperative. Surgery may be required for spinal cord compression or spine instability secondary to extraneural injury (1,2).
- Surgery for adults is often warranted as disc and ligamentum flavum pathology is common (2) [C].
- Early discontinuation of external immobilization is recommended for patients who become asymptomatic, and spinal stability is confirmed with flexion and extension radiographs (5)[C].

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

- Unexplained neurologic findings (2)[C]
- Neurologic injury found via MRI (2)[C]
- Suspected ligamentous lesion (2)[C]
- Trauma and spinal injury protocol
- Rigid immobilization
- Consultation with a spine surgeon

### *Discharge Criteria*

- Neurologic exam without any deficits
- Resolution of transient neurologic symptoms

## ONGOING CARE

- SCIWORA can present with no initial symptoms after trauma followed by subsequent neurologic deterioration.
- Reassess neurologic function within 24 to 48 hours if patient presents with no initial symptoms after a traumatic event, as there may be a latency period and secondary injury.

- Clinical symptoms may take as long as 10 days to develop (3).
- Follow-up MRI before discharge

## PROGNOSIS

- Initial clinical instability, injury severity, MRI findings, neurologic features, injury location, patient age, and persistence of symptoms have a direct correlation with prognosis.
- Favorable
  - Initial mild to moderate injury
  - Normal or mild edema on initial MRI (1)
  - Resolution of changes as evidenced by follow-up MRI
- Unfavorable
  - Initial severe neural injury
  - MRI findings of spinal cord transection and significant hemorrhage
  - Intramedullary hemorrhage seen on MRI is predictive of complete cord injury (1).
  - Follow-up MRI findings of persistent SCI
  - Higher cervical injuries
  - Patients age <8 years (1)
  - Concomitant traumatic brain injury (concussion)

## COMPLICATIONS

Iatrogenic, delayed, and recurrent SCIWORA have been reported; therefore, careful handling of trauma patients and close follow-up is warranted.

## Codes

&NA;

## ICD10

- S14.109A Unsp injury at unsp level of cervical spinal cord, init
- S14.2XXA Injury of nerve root of cervical spine, initial encounter
- S14.102A Unsp injury at C2 level of cervical spinal cord, init encntr

## Clinical Pearls

### &NA;

- If a patient presents with a history of trauma and neurologic symptoms but has negative x-ray and CT findings, consider SCIWORA.
- Spinal cord appearance on MRI provides prognostic information (3)[C].
- Treat SCIWORA with early immobilization, continue for 12 weeks, and avoid high-risk activities for an additional 12 weeks (2)[C].
- Immobilization for 12 weeks is superior to 8 weeks (1)[C].
- Consider serial scans or short-interval follow-up MRI to assess for delayed presentation of pathology (3)[C].

# Scleritis

Matthew J. Schear, DO, MS

Anne Steiner, MD

## BASICS

### DESCRIPTION

- Scleritis is a painful, inflammatory process of the sclera, part of the eye's outer coat.
  - Categorized into anterior or posterior and diffuse, nodular, or necrotizing
  - Commonly associated with systemic disorders
  - Frequently requires systemic anti-inflammatory therapy
  - Potentially vision-threatening
- In contrast, episcleritis is a self-limited inflammation of the eye with only mild discomfort.
- System(s) affected: ocular

### EPIDEMIOLOGY

- Predominant age: most frequently occurs in 4th and 6th decades; mean age for all types of scleritis is 52 years.
- Predominant sex: female > male (1.6:1)

### Incidence

- Anterior scleritis, about 94% of cases (1)[B]
  - Diffuse anterior scleritis (most common)
- Remaining 6% have posterior scleritis

### Prevalence

Estimated to be 6 cases/100,000 people in the general population

### ETIOLOGY AND PATHOPHYSIOLOGY

Frequently associated with a systemic illness (1)[B]

- Most commonly associated with rheumatoid arthritis
- In about 38% of cases, scleritis is the presenting manifestation of an underlying systemic disorder.
- Necrotizing scleritis has the highest association with systemic disease.
- Other etiologies
  - Proposed pathogenesis is dependent on type of scleritis. In necrotizing scleritis, the predominant mechanism is likely due to the activity of matrix metalloproteinases.
  - Drug-induced scleritis has been reported in patients on bisphosphonate therapy.
  - Surgically induced necrotizing scleritis is exceedingly rare and occurs after multiple surgeries.
  - Infectious scleritis occurs most commonly after surgical trauma, and *Pseudomonas aeruginosa* in poorly controlled diabetic patients is the most common causative organism (2) [B].

## **RISK FACTORS**

Individuals with autoimmune disorders are most at risk.

## **COMMONLY ASSOCIATED CONDITIONS**

- Rheumatoid arthritis
- Sjögren syndrome
- Granulomatosis with polyangiitis
- Ankylosing spondylitis
- Systemic lupus erythematosus
- Reactive arthritis
- Relapsing polychondritis
- Polyarteritis nodosa
- Sarcoidosis
- Inflammatory bowel disease
- Herpes zoster
- Herpes simplex

- HIV
- Syphilis
- Lyme disease
- Tuberculosis

## DIAGNOSIS

### HISTORY

- Redness and inflammation of the sclera
  - Can be bilateral in about 40% of cases (1)[B]
- Decrease in visual acuity of two or more Snellen lines occurred in about 16% of patients (1)[B].
- Photophobia and tearing
- Pain ranging from mild discomfort to extreme localized tenderness
  - May be described as constant, deep, boring, or pulsating
  - Pain may be referred to the eyebrow, temple, or jaw.
  - Pain may awaken patient from sleep in early hours of morning.
  - Severe pain is most commonly associated with necrotizing scleritis (1)[B].

### PHYSICAL EXAM

- Examine sclera in all directions of gaze by gross inspection.
  - A bluish hue may suggest thinning of sclera.
  - Inspect for breadth and degree of injection.
- Check visual acuity.
- Slit-lamp exam using red-free light
  - Episcleritis: conjunctival and superficial vascular plexuses displaced anteriorly
  - Scleritis: Deep episcleral plexus is the maximum site of vascular congestion, displaced anteriorly d/t edema of underlying sclera. Characteristic blue or violet color, absent in patients with episcleritis
- Ocular tenderness
- Dilated fundus exam to rule out posterior involvement

- A complete physical exam, particularly of the skin, joints, heart, and lungs, should be done to evaluate for associated conditions.

## *DIFFERENTIAL DIAGNOSIS*

- Conjunctivitis
- Episcleritis
- Iritis (anterior uveitis)
- Blepharitis
- Trauma
- Ocular rosacea
- Herpes zoster

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Consider further tests if warranted by history and physical.
- Routine tests to exclude systemic disease
  - CBC, serum chemistry, urinalysis, ESR, and/or C-reactive protein
- Specific tests for underlying systemic illness
  - Rheumatoid factor, anticyclic citrullinated peptide antibodies, antineutrophil cytoplasmic antibody, and antinuclear antibody may aid in the diagnosis.
- Other tests:
  - Fluorescent treponemal antibody absorption (FTAABS), rapid plasma reagin, and Lyme titers
- Further imaging studies, such as a chest x-ray and sacroiliac joint films, may be useful if a specific systemic illness is suspected.
- B-scan US to detect posterior scleritis and thickness of sclera
- If indicated, MRI/CT scan to detect orbital disease

## *Diagnostic Procedures/Other*

Biopsy is not routinely required unless diagnosis remains uncertain after above investigations.

## *Test Interpretation*

Different subtypes of scleritis are associated with varying presentations and distinct findings.

- Diffuse anterior scleritis: widespread inflammation
- Nodular anterior scleritis: immovable, inflamed nodule

- Necrotizing anterior scleritis
  - With inflammation: Sclera becomes transparent.
  - Scleromalacia perforans without inflammation: painless and often associated with rheumatoid arthritis
- Posterior scleritis: associated with retinal and choroidal complications, adjacent swelling of orbital tissues may occur

## TREATMENT

### GENERAL MEASURES

If scleral thinning, glasses/eye shield should be worn to prevent perforation.

### MEDICATION

- First-line therapies for noninfectious scleritis (3)[C]
  - Oral NSAID therapy, choice based on availability, example is ibuprofen 600 to 800 mg PO TID-QID provided no contraindications exists. About 37% successful (4)[B]
  - Topical steroids as adjunct; prednisolone acetate 1% ophthalmic suspension
  - Subconjunctival triamcinolone acetonide injection only for nonnecrotizing, 40 mg/mL, 97% improvement after one injection. Increased risk of ocular HTN, cataract, and globe perforation (5)[B]
  - Systemic steroids (initial if necrotizing scleritis and preferentially IV if vision threatening, otherwise use if failure of NSAIDs), prednisone 40 to 60 mg PO QD, taper over 4 to 6 weeks
  - Antimetabolites including methotrexate, azathioprine, mycophenolate mofetil, cyclophosphamide, and cyclosporine may be used as steroid-sparing agents. They are generally recommended if steroids cannot be tapered below 10 mg PO QD (4)[C].
- Second-line therapies (4)[C],(5)[B],(6)[A]
  - Immunomodulatory agents, infliximab, and adalimumab can be used if patient has failed or is not a candidate for antimetabolites or calcineurin inhibitors. These agents are preferred over etanercept due to higher treatment success.

- Necrotizing anterior scleritis and posterior scleritis
  - May require immunosuppressive therapy in addition to systemic steroids
  - Treat aggressively due to possible complications if left untreated. May need patch grafting to maintain globe integrity
- Infectious
  - Antibiotic therapy resolves about 18% of cases, whereas the remaining often requires surgical intervention such as debridement (2)[B].

## *ISSUES FOR REFERRAL*

- All patients with scleritis should be managed by an ophthalmologist familiar with this condition.
- Rheumatology referral for coexistent systemic disease is helpful for long-term success.

## *ADDITIONAL THERAPIES*

Immunosuppressants used for autoimmune and collagen vascular disorders may be of help in active scleritis.

## *SURGERY/OTHER PROCEDURES*

- In rare cases, scleral biopsy may be indicated to confirm infection or malignancy.
- Ocular perforation requires scleral grafting.

## **ONGOING CARE**

### *Follow-Up Tests & Special Considerations*

- No restrictions
- Avoid contact lens wear only if there is corneal involvement, which is rare.

### *Patient Monitoring*

- Patient in the active stage of inflammation should be followed very closely by an ophthalmologist to assess the effectiveness of therapy.
- Medication use mandates close surveillance for adverse effects.

## *DIET*

No special diet

# PATIENT EDUCATION

Scleritis at PubMed Health: <http://www.ncbi.nlm.nih.gov/pubmedhealth/PMHT0024411/>

## PROGNOSIS

Scleritis is indolent, chronic, and often progressive.

- Diffuse anterior scleritis (best prognosis)
- Necrotizing anterior scleritis (worst prognosis)
- Recurrent bouts of inflammation may occur.
- Scleromalacia perforans has the highest risk of perforation of the globe.

## COMPLICATIONS

- Decrease in vision, anterior uveitis, ocular hypertension, and peripheral keratitis (1)[B]
- Cataract and glaucoma can result from disease or treatment with steroids.
- Ocular perforation can occur in severe stages.

## Codes

&NA;

### ICD10

- H15.009 Unspecified scleritis, unspecified eye
- H15.019 Anterior scleritis, unspecified eye
- H15.039 Posterior scleritis, unspecified eye

## Clinical Pearls

&NA;

- Episcleritis is a self-limited inflammation of the eye with mild discomfort. Scleritis is a painful, severe, and potentially vision-threatening condition. Both conditions can be associated with underlying inflammatory diseases.
- About 35% of all cases of scleritis are associated with a systemic disease such as rheumatoid arthritis. Necrotizing scleritis has the highest association.

# Scleroderma

Ann M. Lynch, PharmD, RPh, AE-C

Deborah M. DeMarco, MD, FACP

## BASICS

### DESCRIPTION

- Scleroderma (systemic sclerosis [SSc]) is a chronic disease of unknown cause characterized by diffuse fibrosis of skin and visceral organs and vascular abnormalities.
- Most manifestations have vascular features (e.g., Raynaud phenomenon), but frank vasculitis is rarely seen.
- Can range from a mild disease, affecting the skin, to a systemic disease that can cause death in a few months
- The disease is categorized into two major clinical variants (1).
  - Diffuse: distal and proximal extremity and truncal skin thickening
  - Limited
    - Restricted to the fingers, hands, and face
    - CREST syndrome (calcinosis, Raynaud phenomenon, esophageal dysmotility, sclerodactyly, telangiectasia)
- System(s) affected: include, but not limited to skin; renal; cardiovascular; pulmonary; musculoskeletal; gastrointestinal

### *Geriatric Considerations*

Uncommon >75 years of age

### *Pediatric Considerations*

Rare in this age group

### *Pregnancy Considerations*

- Safe and healthy pregnancies are common and possible despite higher frequency of premature births.

- High-risk management must be standard care to avoid complications, specifically renal crisis.
- Diffuse scleroderma causes greater risk for developing serious cardiopulmonary and renal problems. Pregnancy should be delayed until disease stabilizes.

## *EPIDEMIOLOGY*

### *Incidence*

- In the United States: 1 to 2/100,000/year
- Predominant age
  - Young adult (16 to 40 years); middle-aged (40 to 75 years), peak onset 30 to 50 years
  - Symptoms usually appear in the 3rd to 5th decades.
- Predominant sex: female > male (4:1)

### *Prevalence*

In the United States: 1 to 25/100,000

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Pathophysiology involves both a vascular component and a fibrotic component. Both occur simultaneously. The inciting event is unknown, but there is an increase in certain cytokines after endothelial cell activation that are profibrotic (TGF- $\beta$ ; and PDGF).

- Unknown
- Possible alterations in immune response
- Possibly some association with exposure to quartz mining, quarrying, vinyl chloride, hydrocarbons, toxin exposure
- Treatment with bleomycin has caused a scleroderma-like syndrome, as has exposure to rapeseed oil.

### *Genetics*

Familial clustering is rare, but has been seen.

## *RISK FACTORS*

Unknown

# DIAGNOSIS

## HISTORY

- Raynaud phenomenon is generally the presenting complaint (differentiated from Raynaud disease, generally affecting younger individuals and without digital ulcers).
- Skin thickening, “puffy hands,” pruritus, and gastroesophageal reflux disease (GERD) are often noted early in the disease process.

## PHYSICAL EXAM

- Skin
  - Digital ulcerations
  - Digital pitting
  - Tightness, swelling, thickening of digits
  - Hyperpigmentation/hypopigmentation
  - Narrowed oral aperture
  - SC calcinosis
- Peripheral vascular system
  - Telangiectasia
- Joints, tendons, and bones
  - Flexion contractures
  - Friction rub on tendon movement
  - Hand swelling
  - Joint stiffness
  - Polyarthralgia
  - Sclerodactyly
- Muscle
  - Proximal muscle weakness
- GI tract

- Dysphagia
- Esophageal reflux due to dysmotility (most common systemic sign in diffuse disease)
- Malabsorptive diarrhea
- Nausea and vomiting
- Weight loss
- Xerostomia
- Kidney
  - Hypertension
  - May develop scleroderma renal crisis: acute renal failure (ARF)
- Pulmonary
  - Dry crackles at lung bases
  - Dyspnea
- Nervous system
  - Peripheral neuropathy
  - Trigeminal neuropathy
- Cardiac (progressive disease)
  - Conduction abnormalities
  - Cardiomyopathy
  - Pericarditis
  - Secondary cor pulmonale

## *DIFFERENTIAL DIAGNOSIS*

- Mixed connective tissue disease/overlap syndromes
- Scleredema
- Nephrogenic systemic fibrosis
- Toxic oil syndrome (Madrid, 1981, affecting 20,000 people)
- Eosinophilia-myalgia syndrome
- Diffuse fasciitis with eosinophilia

- Scleredema of Buschke

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Nail fold capillary microscopy—drop out is most significant finding
- CBC
- Creatinine
- Urinalysis (albuminuria, microscopic hematuria)
- Antinuclear antibodies (ANA): positive in >90% of patients
- Anti-Scl-70 (anti-topoisomerase [ATA]) antibody is highly specific for systemic disease and confers a higher risk of interstitial lung disease (ILD).
- Anticentromere antibody usually associated with CREST variant
- Chest radiograph
  - Diffuse reticular pattern
  - Bilateral basilar pulmonary fibrosis
- Hand radiograph
  - Soft tissue atrophy and acro-osteolysis
  - Can see overlap syndromes such as rheumatoid arthritis
  - SC calcinosis

### *Follow-Up Tests & Special Considerations*

- Pulmonary function tests (PFTs)
  - Decreased maximum breathing capacity
  - Increased residual volume
  - Diffusion defect
- Antibodies to U3-RNP—higher risk for scleroderma-associated pulmonary hypertension
- Anti-PM-Scl antibodies (for myositis) (2)[B]
- Anti-RNA polymerase III—higher risk for diffuse cutaneous involvement and renal crisis (3)[A]
- ECG (low voltage): possible nonspecific abnormalities, arrhythmia, and conduction defects

- Echocardiography: pulmonary hypertension or cardiomyopathy
- Nail fold capillary loop abnormalities
- Upper GI
  - Distal esophageal dilatation
  - Atonic esophagus
  - Esophageal dysmotility
  - Duodenal diverticula
- Barium enema
  - Colonic diverticula
  - Megacolon
- High-resolution CT scan for detecting alveolitis, which has a ground-glass appearance or fibrosis predominant in bilateral lower lobes

### *Diagnostic Procedures/Other*

- Skin biopsy
  - Compact collagen fibers in the reticular dermis and hyalinization and fibrosis of arterioles
  - Thinning of epidermis, with loss of rete pegs, and atrophy of dermal appendages
  - Accumulation of mononuclear cells is also seen.
- Right-sided heart catheterization: Pulmonary hypertension is an ominous prognostic feature.

---

P.951

### *Test Interpretation*

- Skin
  - Edema, fibrosis, or atrophy (late stage)
  - Lymphocytic infiltrate around sweat glands
  - Loss of capillaries
  - Endothelial proliferation
  - Hair follicle atrophy
- Synovium

- Pannus formation
- Fibrin deposits in tendons
- Kidney
  - Small kidneys
  - Intimal proliferation in interlobular arteries
- Heart
  - Endocardial thickening
  - Myocardial interstitial fibrosis
  - Ischemic band necrosis
  - Enlarged heart
  - Cardiac hypertrophy
  - Pulmonary hypertension
- Lung
  - Interstitial pneumonitis
  - Cyst formation
  - Interstitial fibrosis
  - Bronchiectasis
- Esophagus
  - Esophageal atrophy
  - Fibrosis

## TREATMENT

### GENERAL MEASURES

- Treatment is symptomatic and supportive.
- Esophageal dilation may be used for strictures.
- Avoid cold; dress appropriately in layers for the weather; be wary of air conditioning.
- Avoid smoking (crucial).

- Avoid finger sticks (e.g., blood tests).
- Elevate the head of the bed during sleep to help relieve GI symptoms.
- Use softening lotions, ointments, and bath oils to help prevent dryness and cracking of skin.
- Dialysis may be necessary in renal crisis.

## *MEDICATION*

### *First Line*

- ACE inhibitors (ACEIs): for preservation of renal blood flow and for treatment of hypertensive renal crisis
- Corticosteroids: for disabling myositis, pulmonary alveolitis, or mixed connective tissue disease (not recommended in high doses due to increased incidence of renal failure)
- NSAIDs: for joint or tendon symptoms. Caution with long-term concurrent use with ACEIs (potential renal complications)
- Antibiotics: for secondary infections in bowel and active skin infections
- Antacids, proton pump inhibitors: for gastric reflux
- Metoclopramide: for intestinal dysfunction
- Hydrophilic skin ointments: for skin therapy
- Topical clindamycin, erythromycin, or silver sulfadiazine: for prevention of recurrent infectious cutaneous ulcers
- Consider immunosuppressives for treatment of lifethreatening or potentially crippling scleroderma or interstitial pneumonitis such as cyclophosphamide for ILD (4)[B].
- Nitrates and dihydropyridine calcium-channel blockers for Raynaud phenomenon
- Avoidance of caffeine, nicotine, and sympathomimetics may ease Raynaud symptoms.
- PDE-5 antagonists (e.g., sildenafil), prostanoids, and endothelin-1 antagonists are changing the management of pulmonary hypertension (5).
- Alveolitis: immunosuppressants and alkylating agents (e.g., cyclophosphamide)

## *ADDITIONAL THERAPIES*

- Anti-TNF-*agr* therapy: Preliminary suggestion is that these may reduce joint symptoms and disability in inflammatory arthritis, but small sample sizes and observational biases lend to the need for further well-designed, adequately powered, longitudinal clinical trials.
- Physical therapy to maintain function and promote strength

- Heat therapy to relieve joint stiffness

## ***SURGERY/OTHER PROCEDURES***

- Some success with gastroplasty for correction of GERD
- Limited role for sympathectomy for Raynaud phenomenon
- Lung transplantation for pulmonary hypertension and ILD

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- Monitor every 3 to 6 months for end-organ and skin involvement and medications. Provide encouragement.
- Echocardiology and PFTs yearly

#### ***DIET***

Drink plenty of fluids with meals.

### ***PATIENT EDUCATION***

- Stay as active as possible, but avoid fatigue.
- Printed patient information available from the Scleroderma Federation, 1725 York Avenue, No. 29F, New York, NY 10128; (212) 427-7040
- Advise the patient to report any abnormal bruising or nonhealing abrasions.
- Assist the patient about smoking cessation, if needed.

### ***PROGNOSIS***

- Possible improvement but incurable
- Prognosis is poor if cardiac, pulmonary, or renal manifestations present early.

### ***COMPLICATIONS***

- Renal failure
- Respiratory failure

Flexion contractures

- Disability
- Esophageal dysmotility
- Reflux esophagitis
- Arrhythmia
- Megacolon
- Pneumatosis intestinalis
- Obstructive bowel
- Cardiomyopathy
- Pulmonary hypertension
- Possible association with lung and other cancers
- Death

## See Also

**&NA;**

Morphea

## Codes

**&NA;**

### ICD10

- M34.9 Systemic sclerosis, unspecified
- M34.1 CR(E)ST syndrome
- L94.0 Localized scleroderma [morphea]

## Clinical Pearls

**&NA;**

- Raynaud phenomenon is frequently the initial complaint.
- Skin thickening, puffy hands, and GERD are often noted early in disease.
- Patients must be followed proactively for development of pulmonary hypertension or ILD.

# Seasonal Affective Disorder

Christopher White, MD, JD, MHA

## BASICS

### DESCRIPTION

- Seasonal affective disorder (SAD) is a heterogeneous mood disorder with depressive episodes usually occurring in winter months, with full remissions in the spring and summer.
- Ranges from a milder form (winter blues) to a seriously disabling illness
- Must separate out patients with other mood disorders (such as major depressive disorder and bipolar affective disorder) whose symptoms persist during spring and summer months

### EPIDEMIOLOGY

#### *Incidence*

- Affects up to 500,000 people every winter
- Up to 30% of patients visiting a primary care physician (PCP) during winter may report winter depressive symptoms.
- Predominant age: occurs at any age; peaks in 20s and 30s
- Predominant sex: female > male (3:1)

#### *Prevalence*

- 1-9% of the general population
- 10-20% of patients identified as having mood symptoms will have a seasonal component.

### ETIOLOGY AND PATHOPHYSIOLOGY

The major theories currently involve the interplay of phase-shifted circadian rhythms, genetic vulnerability, and serotonin dysregulation.

- Melatonin produced by the pineal gland at increased levels in the dark has been linked to depressive symptoms; light therapy on the retina acts to inhibit melatonin secretion.
- Serotonin dysregulation because it is secreted less during winter months, must be present for

light therapy to work, and treatment with SSRIs appears to reverse SAD symptoms

- Decreased levels of vitamin D, often occurring during low-light winter months, may be associated with depressive episodes in some individuals experiencing SAD symptoms.

## *Genetics*

- Some twin studies and a preliminary study on GPR50 melatonin receptor variants have suggested a genetic component.
- Recent studies indicate an association with the melanopsin gene (OPN4).
- Increased incidence of depression, ADHD, and alcoholism in close relatives

## *RISK FACTORS*

- Most common during months of January and February: Patients frequently visit PCP during winter months complaining of recurrent flu, chronic fatigue, and unexplained weight gain.
- Working in a building without windows or other environment without exposure to sunlight

## *GENERAL PREVENTION*

- Consider use of light therapy at start of winter (if prior episodes begin in October), increase time outside during daylight, or move to a more southern location.
- Bupropion (Wellbutrin) is an FDA-approved antidepressant for the prevention of SAD.

## *COMMONLY ASSOCIATED CONDITIONS*

Some individuals with SAD have a weakened immune system and may be more vulnerable to infections.

## **DIAGNOSIS**

- Carefully document the presence or absence of prior manic episodes.
- Screen for the existence of any suicidal ideation and safety risk factors.
- Remission of symptoms during spring and summer
- Symptoms have occurred for the past 2 years.
- Seasonal episodes associated with winter months substantially outnumber any nonseasonal depressive episodes.
- Under *DSM-5*, SAD is denoted by adding the "with seasonal pattern" specifier to a diagnosis of major depressive disorder, recurrent.

## HISTORY

- Symptoms of depression meeting the criteria for major depressive disorder are the following:
  - Sleep disturbance: either too much or too little
  - Lack of interest in life and absence of pleasure from hobbies/activities
  - Guilt: feelings of guilt or worthlessness
  - Energy: fatigue or constantly feeling tired
  - Concentration: difficulty with concentration and memory
  - Appetite: changes in appetite and weight
  - Psychomotor retardation: Patients feel slowed down with decreased activity.
  - Suicidal thoughts: Patients report thoughts of suicide.
- In SAD, hypersomnia, hyperphagia (craving for carbohydrates and sweets), and weight gain usually predominate. Despite sleeping more, patients report daytime sleepiness and fatigue. Cravings may lead to binge eating and weight gains >20 lb.
- Obtain collateral history if patient is unable to provide insight into the seasonal component.

## PHYSICAL EXAM

Use exam to exclude other organic causes for symptoms. Focal neurologic deficits, signs of endocrine dysfunction, or stigmata of substance abuse should prompt further testing.

## DIFFERENTIAL DIAGNOSIS

- Similar to that of major depression, meaning that organic causes of low energy and fatigue, such as hypothyroidism, anemia, and mononucleosis (or other viral syndromes), need to be considered.
- Other mood disorders without a seasonal component such as major depression, bipolar disorder, adjustment disorder, or dysthymia
- Symptoms should not be better accounted for by seasonal psychosocial stressors, which often accompany the winter holiday seasons.
- Substance abuse

## DIAGNOSTIC TESTS & INTERPRETATION

- Thyroid-stimulating hormone to rule out hypothyroidism
- CBC to rule out anemia
- Rule out electrolyte and glucose dysregulation.
- 25-OH vitamin D level
- Pregnancy test for women of childbearing potential
- Urine toxicology screen if substance abuse is a concern
- Imaging is not useful unless focal neurologic finding or looking to exclude an organic cause.

## TREATMENT

### *MEDICATION*

Lack of evidence to determine whether light therapy or medication should be the first-line agent. Both supported by the literature and in some studies have equal efficacy. Medications have more side effects. Adherence to both remains a critical issue. The ultimate choice depends on the acuity of the patient and the comfort level of the prescribing clinician with each treatment modality (1)[B].

- SSRIs such as sertraline (Zoloft), paroxetine (Paxil), fluoxetine (Prozac), citalopram (Celexa), and escitalopram (Lexapro) in their traditional antidepressant doses (2)[B]
- Bupropion (Wellbutrin) is the only antidepressant currently approved by the FDA for the prevention of SAD (3)[B].

### *ISSUES FOR REFERRAL*

- Patients with a history of ocular disease should be referred for an ophthalmologic exam before phototherapy and for serial monitoring.
- Patients who fail to respond or who develop manic symptoms or suicidal ideation once treatment is initiated should be considered for psychiatric referral.

### *ADDITIONAL THERAPIES*

- Phototherapy using special light sources has been shown to be effective in 60-90% of patients, often providing relief with a few sessions (2,4)[B].
- Variables that can regulate effect are the following:
  - Light intensity: Although the minimum light source intensity is under investigation, at least 2,500 lux is suggested (domestic lights emit, on average, 200 to 500 lux). There is good

evidence for 10,000 lux as the recommended source (2)[B].

- Treatment duration: Exposure time varies based on intensity of light source, with daily sessions of 30 minutes to a few hours.
  - Time of treatment: Most patients respond better by using the light therapy early in the morning.
  - Color of light source: Emerging data suggest that shorter sessions of lower intensity light-emitting diodes enriched in the blue spectrum have equal efficacy to the traditional white light treatment and possibly capable of being delivered in a transcranial manner (5)[B].
- Light box is placed on table several feet away, and the light is allowed to shine onto the patient's eyes (sunglasses should be avoided). Ensure that the light box has an ultraviolet filter.
  - Most common side effects are eye strain and headache. Insomnia can result if the light box is used too late in the day. Light boxes also can precipitate mania in some patients.
  - Dawn simulation machines gradually increase illumination while the patient sleeps, simulating sunrise while using a significantly less intense light source.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Work to reduce stress levels through meditation, progressive relaxation exercises, and/or lifestyle modification.
- The potential role of vitamin D supplementation is under investigation. Currently, there is a lack of consistent research to satisfactorily demonstrate that treatment improves SAD symptoms. Reported doses vary widely but typically are between 400 and 800 IU/day (6)[B].

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

If the patient develops suicidal ideation as part of his or her depression or mania after treatment is initiated

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Regular monitoring by PCP or psychiatrist for response to treatment; patients may become manic when treated with SSRIs or light therapy.

## *Patient Monitoring*

Patients should be seen in the outpatient clinic weekly to biweekly when initiating light or pharmacotherapy to monitor treatment results, side effects, and any increased suicidal thoughts if using SSRIs.

## *DIET*

No specific diet modification needed

## *PATIENT EDUCATION*

- Increase time outdoors during daylight.
- Rearrange home or work environment to get more direct sunlight through windows.

## *PROGNOSIS*

Symptoms, if untreated, generally remit within 5 months with exposure to spring light, only to return in subsequent winters. If treated, patients usually respond within 3 to 6 weeks.

## **COMPLICATIONS**

Development of suicidal ideation and mania are two outcomes the clinician needs to monitor.

## Codes

### &NA;

## ICD10

- F33.9 Major depressive disorder, recurrent, unspecified
- F33.0 Major depressive disorder, recurrent, mild

- F33.1 Major depressive disorder, recurrent, moderate

## Clinical Pearls

### &NA;

- SAD is a subtype of major depressive disorder. Once the patient has a diagnosed mood disorder, such as depression or bipolar, ask whether the symptoms vary in a seasonal pattern to qualify for the diagnosis of SAD. Generally, these patients will report sleeping too much, eating too much (especially carbs and sweets), and gaining weight during winter months.
- As with all psychiatric diagnoses, ensure that the symptoms are not due to an organic process or better explained by substance abuse.
- Lack of good evidence to decide whether light therapy or SSRIs should be the first-line agent. Guidelines suggest using SSRIs first if the patient is more acute or has contraindications to light therapy or the clinician is not comfortable with light therapy.
- Light therapy boxes are available from numerous online suppliers but are not extensively regulated; practitioners should take care to ensure that patients are using devices from reputable suppliers.
- If using SSRIs, recent studies indicate that some patients may begin to experience increased suicidal thoughts on therapy; these patients need to be monitored closely as outpatients every 1 to 2 weeks. Patients on light therapy also should be monitored closely initially in order to adjust treatment. Once stabilized, both groups of patients can be seen every 4 to 8 weeks during the winter months.
- All patients who demonstrate suicidal ideation or symptoms of mania should be referred for consideration of hospitalization.

# Seizure Disorder, Absence

Felicia Chu, MD

## BASICS

### DESCRIPTION

An absence seizure is a generalized epileptic seizure characterized by a brief lapse of awareness.

### Absence Seizure Types

Absence seizure types according to the International League Against Epilepsy (ILAE) 2010 classification include (1):

- Typical absence
  - Formerly called *petit mal seizures*
  - Abrupt-onset behavioral arrest, loss of awareness, and blank staring, sometimes with mild upward eye deviation, repetitive blinking
  - May include automatisms, tonic or atonic features, eyelid or facial clonus, autonomic features
  - Lasts 5 to 30 seconds
  - Immediate return to normal consciousness
  - Associated with genetic generalized epilepsies, namely, childhood absence epilepsy, juvenile absence epilepsy, and juvenile myoclonic epilepsy
- Atypical absence
  - Onset and offset less abrupt than typical absence seizures
  - Lasts 10 to 45 seconds
  - Impairment of consciousness often incomplete with continued purposeful activity.
  - Postictal confusion sometimes occur.
  - Associated clinical features more pronounced and frequent than in typical absence; atonia is most common.
  - Associated with syndromic epilepsies, such as Lennox-Gastaut and nonsyndromic epilepsies

in patients with developmental delay

- Absence with special features
  - Myoclonic absence:
    - Rhythmic clonic jerking at 2 to 4 Hz which lasts 5 to 10 seconds.
    - Unlike myoclonic seizures with no impairment of consciousness, brief lapses of awareness are characteristic of myoclonic absence.
  - Eyelid myoclonia:
    - Rhythmic clonic jerking of the eyelids at 5 to 6 Hz which lasts 3 to 5 seconds
    - Eyelid myoclonia with absence associated with an impairment of consciousness

## *Epilepsy Diagnoses*

Specific diagnoses according to ILAE (2010):

- Childhood absence epilepsy (CAE)
  - Also known as *pyknolepsy*
  - Typical absence seizures are the only seizure type in 90% of children.
  - 10% develop additional generalized tonic-clonic seizures.
  - Seizures last  $\div$  10 seconds and often occur hundreds of times per day.
  - Normal neurologic state and development
  - Spontaneous remission occurs in 65-70% of patients during adolescence.
- Juvenile absence epilepsy (JAE)
  - Typical absence seizures are the main seizure type.
  - Seizures last longer than in CAE and occur usually less than once a day.
  - Generalized tonic-clonic seizures occur in most patients, often in the first 1 to 2 hours after awakening.
  - Seizures often persist into adulthood.

## *EPIDEMIOLOGY*

- Predominant age
  - CAE: onset ages 4 to 10 years, with peak at ages 5 to 8 years

- JAE: onset ages 9 to 16 years, with peak at ages 10 to 12 years
- Predominant gender
  - Female > male (3:2 to 2:1)
  - Absence epilepsy with myoclonus has male predominance.

### *Incidence*

6 to 8/100,000 per year

### *Prevalence*

5 to 50/100,000

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Corticoreticular theory implicates abnormal activity in thalamocortical circuits.
- Thalamic reticular nucleus is responsible for both normal sleep spindles and pathologic slow-wave discharges; contains inhibitory gamma-aminobutyric acid-ergic (GABAergic) neurons
- These neurons affect low-threshold calcium currents.
- These circuits can fire in oscillatory/rhythmic fashion:
  - Normally, activation of GABA<sub>A</sub> receptors causes 10-Hz oscillations in sleep spindle frequency.
  - If GABA<sub>B</sub> receptors are strongly activated, oscillation frequency will be 3 to 4 Hz, similar to spikeand-wave typical absence seizure frequency.

### *Genetics*

- 70-85% concordance occurs in monozygotic twins; 82% share EEG features.
- 33% concordance among first-degree relatives
- 15-45% have a family history of epilepsy.
- Complex multifactorial inheritance
- For childhood absence, genes/loci implicated include 6q, 8q24, and 5q14.
- Mutations of GABA<sub>A</sub> receptor and voltage-gated Ca<sup>2+</sup> channel are implicated.

## **COMMONLY ASSOCIATED CONDITIONS**

- 3-8% of CAE cases evolve into juvenile myoclonic epilepsy.
- Associated with difficulties in visual attention and visuospatial skills, verbal learning and memory, and reduced language abilities.
- Children with CAE have elevated rates of behavioral and psychiatric comorbidities including attentional deficits, anxiety, depression, isolation, and low self-esteem.
- A large study in 2010 detected overall normal cognition, but 35% of subjects had pretreatment attentional deficits that did not resolve with seizure control.

## DIAGNOSIS

Seizures are often so brief that untrained observers are not aware of the occurrence.

### HISTORY

- Frequently diagnosed in children being evaluated for poor school performance
- Teachers report that child seems to daydream or zone out frequently.
- Child will forget portions of conversations.
- Child with normal IQ underperforms in school.

### PHYSICAL EXAM

- Unless a child has another genetic or acquired abnormality, a neurologic exam usually is normal.
- Seizures may be frequent enough to be observed during physical exam:
  - Manifest by behavioral arrest: Child will stop speaking in midsentence, stare blankly, and so forth
  - Automatisms (repetitive stereotyped behaviors) may be present.
  - Child resumes previous activity.
  - Absence seizures can have a variable effect on respiratory rate, but bradypnea is common.
- Seizures may be induced by hyperventilation:
  - Have the child blow on a pinwheel or similar exercise to provoke seizure.
  - Alternatively, ask the patient to perform hyperventilation with eyes closed and count. Patient will open eyes at onset of seizure and stop counting.
- Patient manifests unresponsiveness but retains postural tone in a typical absence seizure.

## *DIFFERENTIAL DIAGNOSIS*

- Complex partial seizures
- Psychogenic nonepileptic seizures
- Attention deficit hyperactivity disorder (ADHD)
- Confusional states and acute memory disorders
- Migraine variants
- Panic/anxiety attacks
- Breath-holding spells
- Nonepileptic staring spells: Suggestive features include:
  - Events do not interrupt play.
  - Events are first noticed by professional such as school teacher, speech therapist, occupational therapist, or physician (rather than parent).
  - During a staring spell, child is responsive to touch or other external stimuli.

## *DIAGNOSTIC TESTS & INTERPRETATION*

- No specific hematologic workup
- Follow blood chemistry, hepatic function, and blood counts specific to drug regimen.
- Drug levels are useful in evaluating symptoms of toxicity or for breakthrough seizures.

### *Initial Tests (lab, imaging)*

- EEG is standard for diagnosis
  - Typical absence features: 3-Hz spike-and-wave activity on normal EEG background
  - Seizures feature bursts of 3-4-Hz spike-and-wave activity, which may slow to 2.5- to 3-Hz during seizure.
  - Seizure usually is evident clinically if bursts last >3 seconds, subtle changes of transient cognitive impairment may be evident with briefer seizures.
  - Hyperventilation and occasionally photic stimulation may induce seizure, thus confirming diagnosis of typical absence epilepsy. In contrast, atypical absence seizures are not susceptible to induction by hyperventilation or photic stimulation.
- Imaging is not routinely indicated in children with typical absence and normal neurologic exam and IQ.

- Brain MRI is indicated in atypical absence and in children with mixed seizure types when combined with abnormal neurologic exam or low IQ.
- If imaging is performed, MRI is preferable to CT scan due to higher sensitivity for anatomic abnormalities.
- A review of the brain MRIs of 134 patients with idiopathic generalized epilepsy in 2006 showed 24% with structural abnormalities, 88% of which were nonspecific (2)[B].

## TREATMENT

### GENERAL MEASURES

- Review seizure precautions with every patient diagnosed with or suspected to have epilepsy.
- Seizure precautions include bathroom, kitchen, home, driving, outdoors, and sports safety topics, as well as special considerations for parents.

### MEDICATION

Concern regarding generic medications allowing more breakthrough seizures has not been supported in evidence-based studies (3)[A].

#### ALERT

Certain common anticonvulsants may exacerbate absence including carbamazepine, oxcarbazepine, phenytoin, phenobarbital, tiagabine, vigabatrin, pregabalin, and gabapentin.

### First Line

- Ethosuximide blocks T-type calcium channels:
  - First-line, except in absence patients with tonic-clonic seizures (lacks efficacy)
  - High efficacy (4)[A], fastest onset of efficacy (5) [B], and fewer adverse attentional effects compared to valproic acid (4)[A]
  - Side effects: vomiting, diarrhea, abdominal discomfort, hiccups, headache, sedation
  - Adverse effects: rare blood dyscrasias (monitor CBC)
- Valproic acid has multiple mechanisms:
  - First choice in absence patients with tonic-clonic, myoclonic, mixed seizure types

- Very effective but has highest rate of adverse events leading to treatment discontinuation, including negative attentional effects (4)[A]
- Side effects: tremor, drowsiness, dizziness, weight gain, alopecia, sedation, vomiting
- Adverse effects: teratogenicity, pancreatitis, thrombocytopenia, rare fulminant hepatic failure (especially in children <2 years)

## *Second Line*

- Lamotrigine affects sodium channels:
  - Controls seizures but may be less efficacious than ethosuximide or valproic acid (4)[A]
  - May be equally as efficacious for new-onset CAE (5)[B]
  - Side effects: rash, diplopia, headache, insomnia, dizziness, nausea, vomiting, diarrhea
  - Adverse effects: rare Stevens-Johnson rash, more often when coadministered with valproic acid
- Topiramate affects GABA and excitatory neurotransmission:
  - FDA-approved for Lennox-Gastaut syndrome
  - Side effects: psychomotor slowing
  - Adverse effects: weight loss, renal stones, myopia, glaucoma (rare), anhidrosis
- Levetiracetam is used off-label:
  - Has been used as both monotherapy and adjunct therapy for absence seizures
  - A small multicenter randomized controlled trial (RCT) showed modest efficacy but not statistically significant versus placebo (6)[C].
- Zonisamide is also used off-label.
- Clonazepam, nitrazepam, and clobazam may be effective in the short-term but are not recommended for long-term management due to development of tolerance (few months to a year) and side effects.

## *Pregnancy Considerations*

Anticonvulsants, especially valproic acid, are associated with an increase in fetal malformations. Use of valproic acid in women who are or are likely to become pregnant generally is contraindicated. Obtain specialty consultation.

## *ADDITIONAL THERAPIES*

- Most absence seizure patients respond to a single medication.
- Male sex and an early age at diagnosis are associated with the need for two medications to control the disease (7)[B].
- Vagal nerve stimulator (VNS) may be considered as an option for medically refractory absence epilepsy (8)[C].

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Absence epilepsy rarely requires admission.
- Status epilepticus requires inpatient management.

### *Discharge Criteria*

Resolution of status epilepticus

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Patients with associated tonic-clonic seizures should avoid high places and swimming alone.
- Absence rarely persists into adulthood, but affected adults may be restricted from driving, working over open flames, and so forth, as with other generalized and partial epilepsy subtypes.
- Patients should be monitored periodically by a neurologist for evolution of absence epilepsy into tonic-clonic or other seizure types.

### *PROGNOSIS*

- Patients whose shortest pretreatment EEG seizures are >20 seconds in duration are more likely to achieve seizure freedom, regardless of treatment (9)[A].
- Of those with CAE without tonic-clonic seizures, 90% remit by adulthood.
- 35% of patients with tonic-clonic seizures experience complete remission of absence seizures.
- 15% of patients develop juvenile myoclonic epilepsy.

### **COMPLICATIONS**

Reported frequencies of typical absence status epilepticus range from 5.8% to

- G40.419 Oth generalized epilepsy, intractable, w/o stat epi
- G40.401 Oth generalized epilepsy, not intractable, w stat epi

## Clinical Pearls

**&NA;**

- If parents are unable to determine the cause of a staring spell, try suggesting that parents mention something exciting or unexpected like Òice creamÓ during a spell to get the child's attention rather than calling his or her name.
- To help aid with diagnosis during an exam, try having the child blow repetitively on a pinwheel (causing hyperventilation) to attempt to trigger absence seizure.
- Ethosuximide and valproic acid are first-line agents in treatment of absence seizures. Valproic acid and lamotrigine are recommended for absence patients with tonic-clonic and mixed seizure types.

# Seizure Disorder, Partial

Noel Dunn, MD

David Haight, MD

## BASICS

### *DESCRIPTION*

- Seizures occur when abnormal synchronous neuronal discharges in the brain cause transient cortical dysfunction.
- Generalized seizures involve bilateral cerebral cortex from the seizure's onset.
- Partial seizures originate from a discrete focus in the cerebral cortex.
- Partial seizures are further divided into simple and complex subtypes:
  - If consciousness is impaired during a partial seizure, it is classified as complex.
  - If consciousness is preserved, it is a simple partial seizure.

### *EPIDEMIOLOGY*

#### *Prevalence*

Partial seizures occur in 20/100,000 persons in the United States.

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Partial seizures begin when a localized seizure focus produces an abnormal, synchronized depolarization that spreads to a discrete portion of the surrounding cortex.
- The area of cortex involved in the seizure determines the symptoms; for example, an epileptogenic focus in motor cortex produces contralateral motor symptoms.
- In some cases, etiology is related to structural abnormalities that are susceptible to epileptogenesis. Most common etiologies vary by life stage:
  - Early childhood: developmental/congenital malformation, trauma
  - Young adults: developmental, infection, trauma
  - Adults 40 to 60 years of age: cerebrovascular insult, infection, trauma

- Adults >60 years of age: cerebrovascular insult, trauma, neoplasm
- Complex partial seizures: A common cause is mesial temporal sclerosis.

## Genetics

Benign rolandic epilepsy, a form of partial seizure disorder, has an autosomal dominant inheritance pattern with penetrance depending on multiple factors.

## RISK FACTORS

- History of traumatic brain injury (1)[B]
- Children exposed to a thiamine-deficient formula (2)[C].

## COMMONLY ASSOCIATED CONDITIONS

Epilepsy patients have a higher incidence of depression than the general population.

## DIAGNOSIS

- Seizure activity usually stereotyped.
- Duration: Seconds to minutes, unless status epilepticus develops; status epilepticus may present as focal/generalized convulsions/altered mental status without convulsions.
- Simple partial seizures
  - Simple partial seizures are characterized by localized symptoms. The patient is conscious. Symptoms may involve motor, sensory, or psychic systems.
  - Motor: Seizure activity in motor strip causes contraction (tonic) or rhythmic jerking (clonic) movements that may involve one entire side of body or may be more localized (i.e., hands, feet, or face).
    - Jacksonian march: As discharge spreads through motor cortex, tonic-clonic activity spreads in predictable fashion (i.e., beginning in hand and progressing up arm and to the face).
  - Sensory/psychic
    - Todd paralysis: after motor seizure, residual, temporary weakness in the affected area
    - Parietal lobe: sensory loss/paresthesias, dizziness
    - Temporal lobe: dŹj^ vu, rising sensation in epigastrium, auditory hallucinations/forced memories, unpleasant smell/taste

- Occipital: visual hallucinations
- Complex partial seizures
  - Impaired consciousness by definition
  - May have aura; this is start of seizure.
- Amnesia for the event, postictal confusion
  - Most often, focus in complex partial seizures is temporal/frontal.
  - Motor manifestations may include dystonic posturing/automatisms (i.e., simple, repetitive movements of face and hands such as lip smacking, picking, or more complex actions such as purposeless walking).
  - Frontal lobe seizure is characterized by brief, bilateral complex movements, vocalizations, often with onset during sleep.

## **HISTORY**

- A detailed description of the seizure should be obtained from an observer.
- Review medication list for drugs that lower seizure threshold (e.g., tramadol, bupropion, theophylline).
- Obtain history of drugs of abuse (e.g., cocaine), as they may lower seizure threshold.
- Review history of any prior traumatic brain injury.

## **PHYSICAL EXAM**

Include neurologic exam, with attention to lateralizing signs suggestive of structural lesion.

## **DIFFERENTIAL DIAGNOSIS**

- Nonepileptic seizure
- Syncope/postanoxic myoclonus
- Hypoglycemia
- For hemiparesis following event
  - Transient ischemic attack
  - Hemiplegic migraine

## **DIAGNOSTIC TESTS & INTERPRETATION**

EEG: spikes/sharp waves over seizure focus

- Yield of EEG is increased by being obtained in the first 24 hours following seizure and by sleep deprivation.
- Frontal lobe seizure focus may be difficult to detect by routine EEG.
- If difficulty with diagnosis, continuous video-EEG monitoring may be appropriate.
- Serum electrolytes, including calcium, magnesium, phosphorus; hepatic function panel; CBC; drugs of abuse urine drug screen
- Elevated prolactin, if measured within 10 to 20 minutes of suspected seizure, or elevated creatine phosphokinase; if measured within 6 to 24 hours, may help to differentiate generalized/complex partial seizure from psychogenic seizure (3)[B].
- CSF exam if infection is suspected.
- Urinalysis, chest x-ray, levels of antiepileptic drugs for breakthrough seizure
- Technologic advances in neuroimaging are usually directed at the diagnosis and prognosis for seizure control (4)[C].
- Emergency evaluation of new seizure: CT scan to screen for hemorrhage and stroke
- After emergency evaluation, MRI with thin cuts through area of interest
- If planning epilepsy surgery, positron emission tomography (PET) scan and/or interictal singlephoton emission computed tomography (SPECT) may be of value.
- Magnetoencephalography (MEG) is an evolving technology for localizing seizure focus.

## TREATMENT

### GENERAL MEASURES

- Ask the patient to maintain a seizure diary.
- Note potential triggers, such as stress, sleep deprivation, drug use, discontinuation of alcohol/benzodiazepines, menses.

### MEDICATION

- Current guidelines do not recommend for or against starting an antiepileptic drug (AED) after a single unprovoked seizure. Patients should be counseled that AEDs will reduce risk of repeat seizure over 2 years but have no effect on long-term remission (5)[C].
- AEDs act on voltage-gated ion channels, affect neuronal inhibition via enhancement of *g<sub>g</sub>*:-

aminobutyric acid (GABA, an inhibitory neurotransmitter), or decrease neuronal excitation. End result is to decrease the abnormal synchronized firing and to prevent seizure propagation.

- 50% of those with newly diagnosed partial seizures respond to, and tolerate, first AED trial. Up to 50% of those who fail the first AED trial will also fail a second AED trial (6)[B].
- Choose AED based on seizure type, side effect profile, and patient characteristics. Increase dose until seizure control is obtained/side effects become unacceptable.
- Attempt monotherapy, but many patients will require adjunctive agents.
- *Refractory to medications* is defined as failure of at least three anticonvulsants to achieve adequate control.
- AEDs may prevent seizures after a traumatic brain injury (TBI) in the short-term, although they provide no efficacy in long-term prevention (7)[B].
- Several AEDs induce/inhibit cytochrome P450 enzymes (watch for drug interactions).

### *First Line*

- Carbamazepine: Affects sodium channels; side effects include GI distress, hyponatremia, diplopia, dizziness, rare pancytopenia/marrow suppression, and exfoliative rash.
- Oxcarbazepine: Affects sodium channels; side effects include dizziness, diplopia, hyponatremia, and headache.
- Lamotrigine: Affects sodium channels.
  - Side effects include insomnia, dizziness, and ataxia.
  - Risk of Stevens-Johnson reaction (potentially fatal exfoliative rash), especially when given with valproate, requires slow titration.
- Levetiracetam: multiple mechanisms; side effects include sedation, ataxia, and irritability.

---

P.957

### *Second Line*

- Phenytoin: Affects sodium channels; side effects include ataxia, dizziness, diplopia, tremor, GI upset, gingival hyperplasia, and fever.
- Phenobarbital: multiple mechanisms; side effects include sedation and withdrawal seizures.
- Valproate: multiple mechanisms; side effects include GI upset, weight gain, alopecia, and tremor; less common, thrombocytopenia, hepatitis, pancreatitis
- Topiramate: multiple mechanisms; side effects include anorexia, cognitive slowing, sedation, nephrolithiasis, and anhidrosis.

- Gabapentin: multiple mechanisms; side effects include sedation, dizziness, and ataxia.
- Pregabalin: Affects calcium channels; side effects include sedation, dizziness, and weight gain.
- Zonisamide: Affects sodium channels.
  - Side effects include sedation, anorexia, nausea, dizziness, ataxia, anhidrosis, and nephrolithiasis.
  - Cross-reaction with sulfa allergy

## *Pregnancy Considerations*

- Folate should be prescribed for all women of childbearing age who are taking AEDs. AED therapy during the 1st trimester is associated with doubled risk for major fetal malformations (6% vs. 3%).
- Phenytoin in pregnancy may result in fetal hydantoin syndrome.
- Valproate is associated with neural tube defects.
- Fetal insult from seizures following withdrawal of therapy also may be severe. Risk-to-benefit balance should be evaluated with high-risk pregnancy and neurology consultations. Most patients remain on anticonvulsants.
- Consider vagal nerve stimulator during pregnancy (8)[B].

## *ISSUES FOR REFERRAL*

For refractory seizures, consider referral to an epilepsy specialist (9)[B].

## *ADDITIONAL THERAPIES*

- Vagal nerve stimulator provides periodic stimulation to vagus nerve; may induce hoarseness, cough, and dysphagia. High-frequency stimulation in adults provides greater reduction in seizure frequency than low-frequency stimulation but also has greater rates of side effects (10) [B].
- Deep brain stimulation may decrease seizure frequency in medically refractive epilepsy but its efficacy varies by seizure source location (11)[B].
- Repetitive magnetic transcranial stimulation may reduce the frequency of seizures in individuals with refractory focal seizures (12)[B].

## *SURGERY/OTHER PROCEDURES*

- For refractory partial complex seizures with identifiable focus

Preoperative testing, such as Wada test, should be done to decrease likelihood of inducing aphasia and memory loss.

- 34-74% will be seizure-free after temporal lobe surgery. Prognosis varies for surgical resection of extratemporal foci (13)[B].
- Goal of surgical intervention is to reduce reliance on medications; most patients remain on anticonvulsants postoperatively.

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

Admit for unremitting seizure (partial/secondary generalized status epilepticus).

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Most states have restrictions on driving for those with seizure disorders.
- Depending on seizure manifestation, may also recommend against activities such as swimming, climbing to heights, or operating heavy machinery

### ***Patient Monitoring***

AED levels if concern over toxicity, noncompliance, or for breakthrough seizures

### ***DIET***

Ketogenic or low-glycemic index diet may improve seizure control in some patients but is not welltolerated (14)[B].

## ***PATIENT EDUCATION***

Avoid potential triggers such as alcohol or drug use and sleep deprivation.

## ***PROGNOSIS***

- Risk of seizure recurrence: ÷30% after first seizure; of these, 50% will occur in the first 6 months; 90% in the first 2 years.
- Depends on seizure type; rolandic epilepsy has a good prognosis; temporal lobe epilepsy is more likely to be persistent.
- ÷25-30% of all seizures are refractory to current medications.

- AEDs initiated after an initial seizure have been shown to decrease the risk of seizure over the first 2 years but are not demonstrated to reduce longterm risk of recurrence.
- The potential for AEDs to confer neuroprotection is under investigation.
- The risk of developing seizure after mild TBI remains high for a long period (>10 years) (1)[B].

## COMPLICATIONS

- Risk of accidental injury
- Up to 50-60% of individuals with epilepsy will also have a mood disorder, the most common being depression and anxiety.
- 20-30% of individuals with epilepsy will have memory impairment.

## Clinical Pearls

### &NA;

- It is controversial whether AED treatment is indicated after a first seizure. Treatment should be strongly considered when a clear structural cause is identified/risk of injury from seizure is high (e.g., osteoporosis, anticoagulation).
- Consider vagus nerve stimulation in pregnancy and in patients with medically refractory seizures.
- Postictal elevation in prolactin and CPK levels can help distinguish physiologic from psychogenic seizures.

# Seizures, Febrile

Brigitte N. Ngo, DO

Swati Avashia, MD, FAAP

## BASICS

### DESCRIPTION

- By definition, febrile seizures occur in pediatric patients aged 6 months to 5 years with fever  $\geq 100.4^{\circ}\text{F}$  ( $38^{\circ}\text{C}$ ). Evidence of an underlying neurologic abnormality, metabolic condition, or intracranial infection excludes this diagnosis.
- Distinguished as simple or complex based on multiple criteria (1):
  - Simple (65-90%; must meet all criteria)
    - Generalized clonic or tonic-clonic seizure activity without focal features
    - Duration <15 minutes
    - Does not recur within 24 hours
    - Resolves spontaneously
    - No history of previous afebrile seizure or seizure disorder
  - Complex (20-30%; only one criterion must be met)
    - Partial seizure, focal activity
    - Duration >15 minutes
    - Recurs within 24 hours

### EPIDEMIOLOGY

#### Incidence

- Approximately 500,000 febrile seizures occur in the United States annually.
- Most occur in children 6 months to 3 years old; only 6-15% occur in patients  $\geq 4$  years
- Peak incidence is 18 months of age.

Risk of recurrence is 30-50% (2).

- Follows a bimodal seasonal pattern that mirrors peaks of febrile respiratory (November to January) and gastrointestinal infections (June to August).

## *Prevalence*

- 2-5% of children in United States and Western Europe have at least one febrile seizure.
- Cumulative incidence varies in other populations (0.5-14%), with higher prevalence in Asia (3).

## *ETIOLOGY AND PATHOPHYSIOLOGY*

A variety of mechanisms have been proposed:

- A lower baseline seizure threshold in the age group affected by febrile seizures.
- Familial genotypes may result in lower seizure thresholds.
- Fever may alter ion channel activity, resulting in increased circuit excitability.
- Cytokines released secondary to infection, specifically interleukin (IL)-1, increase neuronal activity.

## *Genetics*

- Evidence for genetic association:
  - Greater concordance in monozygotic than dizygotic twins
  - Risk of febrile seizure with a previously affected sibling is increased.
  - Having two affected parents doubles a child's risk of febrile seizure.
  - Positive family history can be seen in 25-40% of cases (4).
- Several rare familial epileptic syndromes present with febrile seizure.

## *RISK FACTORS*

- Family history of febrile seizures; risk increases with the number of affected first-degree relatives.
- Any condition causing fever
- Recent vaccination
  - As febrile seizures are a benign entity, the benefits of vaccination outweigh the risk.
  - Risk increases after the administration of all measles-containing vaccines; peak incidence

occurs 7 to 10 days after vaccination.

- Risk increases on the day of DTaP-IPV-Hib combination vaccine administration, as fever rate increases by 70% compared to giving them separately.
- Absolute vaccination-associated risk is very low.
- Prenatal exposure to alcohol and tobacco, iron deficiency anemia, daycare attendance, developmental delay, premature birth, and prolonged NICU stay
- Children with iron deficiency anemia may have increased risk for febrile seizures. Consider checking for anemia if the history suggests a risk for iron deficiency (5)[C].

## GENERAL PREVENTION

Prevention is not usually indicated given the benign nature of this condition, lack of effective interventions, and side effects of prophylactic medications.

## COMMONLY ASSOCIATED CONDITIONS

- Viral infections: Frequently implicated pathogens include human herpesvirus 6, influenza, parainfluenza, adenovirus, and respiratory syncytial virus (RSV).
- Bacterial infections: Frequently associated infections include otitis media, pharyngitis, urinary tract infection (UTI), pneumonia, and gastroenteritis.

## DIAGNOSIS

### HISTORY

- History of present illness:
  - Description of seizure:
    - Febrile seizures are generalized with clonic or tonic-clonic activity.
    - Absence, myoclonic, atonic, and focal seizures are atypical of febrile seizures and warrant further evaluation.
  - Seizure duration
  - Presence of postictal state (consistent with febrile seizure)
  - Number of seizures in previous 24 hours
  - Lethargy, irritability, or decreased level of consciousness as reported by the caretaker
  - Symptoms of underlying infection
  - Symptoms concerning for neurologic deficits

- Past medical history:
  - Existing conditions, including developmental delay, cerebral palsy, and metabolic disorders
  - Recent antibiotic course
  - History of febrile seizures
  - History of afebrile seizures or seizure disorder
  - History of head injury
  - Vaccination status, recent immunization
- Family history: febrile seizures, afebrile seizures, epilepsy, metabolic disorders, and other neurologic conditions
- Social history: factors concerning for child abuse

## *PHYSICAL EXAM*

- Vital signs should be stable and consistent with intercurrent febrile illness; unstable vital signs or toxic appearance warrant further evaluation.
- Identify the presence or absence of focal deficits on a complete neurologic exam.
- Assess for signs of meningitis, including decreased level of consciousness, irritability, meningeal signs, bulging fontanelle, papilledema, and petechiae.
- Identify cause of fever.
- Assess thoroughly for manifestations of child abuse with a careful skin exam, inspection and palpation for occult trauma, and retinal exam if possible.

## *DIFFERENTIAL DIAGNOSIS*

- Seizures due to an etiology other than febrile seizure:
  - Meningitis, encephalitis
  - Primary epilepsy
  - Neonatal seizure
  - Dravet syndrome
  - Intracranial mass
  - Nonaccidental trauma
  - Electrolyte abnormality
  - Hypoglycemia

- Metabolic disorder
- Conditions presenting similarly to seizure:
  - Rigors
  - Crying
  - Benign myoclonus of infancy
  - Breath-holding spell
  - Choking episode
  - Tic disorder
  - Parasomnia
  - Arrhythmia
  - Metabolic disorder
  - Dystonic reaction

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Routine laboratory tests are not recommended to identify an underlying cause of a simple febrile seizure (1)[C].
- Rates of UTI in children with simple febrile seizures and in febrile children without seizure are comparable; consider obtaining urinalysis for susceptible patients (2)[B].
- Blood glucose if the patient is convulsing or is obtunded on presentation (2)[B].
- Lumbar puncture
  - In studies of patients with simple febrile seizures conducted since the initiation of routine infant vaccination against *Haemophilus influenzae*, rates of acute bacterial meningitis were very low (0-0.8%).
  - Seizure is unlikely to be the only presenting symptom of meningitis. Symptoms indicating increased likelihood of meningitis include toxic appearance, altered level of consciousness, meningeal signs, focal neurologic deficits, bulging fontanelle, and petechiae.
  - Cases of bacterial meningitis in children with febrile seizures who return to baseline or in the absence of other signs or symptoms are rare (6).
  - Recommendations:
    - Lumbar puncture should be performed in a child with fever and seizure if meningeal signs are present or if there is concern for meningitis or other intracranial pathology

based on history and exam (7)[B].

- In infants aged 6 to 12 months, consider lumbar puncture if the child has not been vaccinated against *H. influenzae* or *Streptococcus pneumoniae* according to schedule (7) [C].
- Consider lumbar puncture for children with fever and seizure who have recently been treated with antibiotics, as antibiotics may mask meningeal signs and symptoms (7)[C]. The yield of lumbar puncture in children with complex febrile seizure is very low; however, some recommend considering a lumbar puncture in these patients (6)[B].

P.959

- Neuroimaging is not routinely recommended for the purposes of identifying the cause of a simple febrile seizure (7)[B].
- Studies have demonstrated limited use of emergent imaging in patients who meet criteria for complex febrile seizure based on multiple episodes in 24 hours; however, imaging may be indicated for focal findings or concerning history or exam. There are no current guidelines regarding imaging with complex febrile seizures (8)[B].

## *Diagnostic Procedures/Other*

- EEG is not recommended in neurologically normal children presenting with simple febrile seizure (7)[B].
- There is mixed evidence for use of EEG after complex febrile seizures; some recommend outpatient EEG on follow-up.

## **TREATMENT**

### *GENERAL MEASURES*

- Acute seizure management
  - Airway: Position the patient laterally, suction secretions, and place a nasopharyngeal airway if necessary.
  - Breathing: Administer oxygen for cyanosis; consider bag-mask ventilation or intubation for inadequate ventilation.
  - Circulation: Establish IV access if first-line buccal or nasal midazolam is not effective.
- Antipyretics are helpful for patient comfort but do not prevent seizure recurrence during the initial febrile episode (1)[A].

Provide supportive care and treat underlying infection if necessary.

## *MEDICATION*

### *First Line*

Treat seizures of  $\geq 5$  minutes duration with anticonvulsants:

- Buccal midazolam 0.5 mg/kg or nasal midazolam 0.2 mg/kg (3)
- IV or IM lorazepam 0.1 mg/kg

### *Second Line*

Rectal diazepam is less effective and more commonly associated with respiratory depression than first-line treatments (1)[B].

## *ISSUES FOR REFERRAL*

Simple febrile seizures do not require referral to a pediatric neurologist.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Unstable vital signs
- Concerning findings on history or physical exam
- Prolonged seizure requiring anticonvulsants
- Persistent change in mental status
- Inpatient management of underlying condition is required.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Anticonvulsant prophylaxis during subsequent febrile episodes (1)[B]:
  - The American Academy of Pediatrics recommends against prophylaxis with anticonvulsants due to an unacceptable risk-benefit ratio.
  - Phenobarbital is effective but can have serious side effects, including lowering IQ.
  - Prophylaxis with valproic acid may be effective but can cause hepatotoxicity and/or hyperammonemia.

- Prophylaxis with phenytoin and carbamazepine is ineffective.
- Oral and rectal diazepam are effective but are not recommended due to the benign nature of febrile seizures.
- Antipyretic prophylaxis during subsequent febrile episodes (1)[A]:
  - No study has demonstrated that fever management will prevent recurrence.
  - Ibuprofen and acetaminophen are no more effective than placebo in preventing recurrence.

## *PATIENT EDUCATION*

There is frequently a high degree of parental anxiety associated with febrile seizures. Suggested anticipatory guidance:

- Febrile seizures do not cause brain damage and are associated with a low risk for sequelae.
- Parents should be reassured after a simple febrile seizure that there is no negative impact on intellect, behavior, or risk of death (1)[B].
- Parents should be prepared for a high probability of recurrence.
- If seizure recurs, position the child safely and do not intervene inappropriately.
- Time the seizure; call rescue if the child turns blue, has difficulty breathing, or the seizure lasts >5 minutes.
- If the seizure spontaneously resolves in <5 minutes and the child is well but sleepy, seek immediate attention, but calling rescue is not necessary.

## *PROGNOSIS*

- Recurrence:
  - Estimates of recurrence rates vary (30-50%).
  - Factors associated with seizure recurrence include age < 12 months at time of first episode, first-degree relative with history of febrile seizure, and history of complex febrile seizures.
- Intellectual and behavioral outcomes (2)
  - Febrile seizures do not impact IQ, behavioral abnormalities, academic performance, or neurocognitive inattention.
  - Outcomes in children with single and multiple febrile seizures are similar.
- Subsequent development of epilepsy (2)

Risk of epilepsy after a simple partial seizure is approximately 1% compared to the general population.

- Risk is 2.4% in those with multiple simple febrile seizures, age <12 months at time of initial episode and a family history of epilepsy.
  - Factors associated with increased risk include presenting with complex febrile seizure, family history of epilepsy or febrile seizures, cerebral palsy, developmental delay, low birth weight, and prematurity.
- Mortality (2):
    - A slight increase in mortality is attributable in part to underlying neurodevelopmental abnormalities and to the subsequent development of epilepsy.
    - There is not an increased risk for SIDS in siblings of children who have febrile seizures.

## COMPLICATIONS

Seizure-related injury, aspiration pneumonia, side effects of prescribed medications or diagnostic procedures, and subsequent parental perception of the child as being vulnerable, especially during subsequent fevers.

## Codes

**&NA;**

### ICD10

- R56.00 Simple febrile convulsions
- R56.01 Complex febrile convulsions
- G40.901 Epilepsy, unsp, not intractable, with status epilepticus

## Clinical Pearls

**&NA;**

- Febrile seizures are generally benign, and families can be reassured that children are at low risk of death, subsequent development of epilepsy, and learning or behavioral abnormalities.
- History and physical exam are important tools in identifying children presenting with febrile seizure who may be at greater risk for meningitis or other intracranial pathology.
- For simple febrile seizures, routine labs, lumbar puncture, neuroimaging studies, and EEG are not recommended in the absence of clinical suspicion of serious underlying pathology.
- Prophylaxis with anticonvulsants or antipyretics during subsequent febrile episodes is not recommended due to their lack of effectiveness and the risk of medication-associated side effects.

# Sepsis

Patricia Martinez Quinones, MD

Jin Sol Oh, MD

Steven B. Holsten Jr., MD, FACS

## BASICS

### DESCRIPTION

- A systemic inflammatory response secondary to known or suspected infection
- Synonym(s): septicemia
- Systemic inflammatory response syndrome (SIRS)
  - Temperature  $>38.3^{\circ}\text{C}$  ( $100.9^{\circ}\text{F}$ ) or  $<36^{\circ}\text{C}$  ( $96.8^{\circ}\text{F}$ )
  - Heart rate (HR)  $>90$  beats/min
  - Respiratory rate (RR)  $>20$  breaths/min
  - WBC  $> 12,000$  cells/ $\text{mm}^3$ , or  $<4,000$  cells/ $\text{mm}^3$
- Sepsis signs and symptoms (1)[C]
  - General variables
    - Temperature  $>38.3^{\circ}\text{C}$  ( $100.9^{\circ}\text{F}$ ) or  $<36^{\circ}\text{C}$  ( $96.8^{\circ}\text{F}$ ); HR  $>90$  beats/min or  $>2$  standard deviations (SD) above normal for age
    - Tachypnea (RR  $>20$  breaths/min or  $\text{PCO}_2 <32$  mm Hg)
    - Acute altered mental status (AMS)
    - Significant edema or positive fluid balance ( $>20$  mL/kg over 24 hours)
    - Hyperglycemia (plasma glucose  $>140$  mg/dL or  $7.7$  mmol/L) in the absence of diabetes
  - Inflammatory variables
    - Leukocytosis (WBC  $> 12,000$  cells/ $\text{mm}^3$ ), or leukopenia ( $<4,000$  cells/ $\text{mm}^3$ ), or normal WBC with  $> 10\%$  bands
    - Plasma C-reactive protein (CRP)  $>2$  SD above normal

- Plasma procalcitonin >2 SD above normal
- Hemodynamic variables
  - Arterial hypotension (SBP <90 mm Hg, MAP <70, or SBP decrease of >40 mm Hg in adults or <2 SD below normal for age)
- Organ dysfunction variables
  - Arterial hypoxemia ( $\text{PaO}_2/\text{FIO}_2 < 300$ )
  - Acute oliguria (urine output <0.5 mL/kg/hr for at least 2 hours with or without adequate resuscitation)
  - Creatinine increase >0.5 mg/dL or 44.2  $\mu\text{mol/L}$
  - Coagulation abnormalities (INR >1.5 or aPTT >60 seconds)
  - Ileus (absent bowel sounds)
  - Thrombocytopenia (platelet <100,000)
  - Hyperbilirubinemia (plasma total bilirubin >4 mg/dL or 70  $\mu\text{mol/L}$ )
- Tissue perfusion variables
  - Elevated serum lactate (>1 mmol/L)
  - Decreased capillary refill or skin mottling
- Severe sepsis: sepsis-induced hypoperfusion or acute organ dysfunction
- Septic shock: refractory hypotension, unexplained by other causes, and despite adequate fluid resuscitation:
  - Hypotension is defined as SBP <90 mm Hg, MAP <70 mm Hg, and reduction in SBP >40 mm Hg from baseline.

## *Pediatric Considerations*

- Continuum from sepsis to multisystem organ failure (MSOF) is affected by age-specific physiologic variables in children.
- SIRS in pediatric population requires that abnormality in temperature or WBC be present (2) [C].
- Drug metabolism is reduced in children with severe sepsis. Monitor drug toxicity labs to prevent adverse effects.

## Geriatric Considerations

Often more difficult to diagnose; change in mental status/behavior may be the only early manifestation.

## EPIDEMIOLOGY

### Incidence

- 3/1,000 population
- Increasing incidence; 750,000 new cases annually in the United States
- 2% of hospitalized patients

## ETIOLOGY AND PATHOPHYSIOLOGY

- Multifactorial: Widespread endothelial dysfunction, dysregulation of nitric oxide production, and activation of coagulation cascade leads to maldistribution of blood flow, tissue hypoperfusion, and resulting to organ dysfunction.
- An imbalance between proinflammatory and antiinflammatory mediators leads to systemic tissue damage and significant immunosuppression.
- Causative organisms:
  - Gram-positive bacteria (most common): *Staphylococcus* sp., *Streptococcus* sp., *Enterococcus* sp.
  - Gram-negative: *Escherichia coli*, *Klebsiella* sp., *Proteus* sp., *Pseudomonas* sp. and anaerobic bacteria
  - Fungi: *Candida* sp. (incidence increased 207% from 1976 to 2000)
  - Causative organism not identified in 50-75% of cases
- Common sites of infection: respiratory tract (most common), urinary tract, gastrointestinal tract, skin/soft tissue, CNS, bacteremia

## RISK FACTORS

- Extremes of age (very young or age >60 years)
- Ethnicity: African American
- Comorbidities: COPD, congestive heart failure (CHF), cancer, diabetes, and renal insufficiency/failure
- Immunosuppression

- Bacteremia
- Community-acquired pneumonia
- Complicated labor and delivery: premature labor and/or premature rupture of membranes, untreated maternal group B strep colonization
- Nosocomial factors: surgical site infections, indwelling catheters

## GENERAL PREVENTION

- Vaccination: pneumococcal vaccine in children and also adults who are  $\geq 65$  years or with comorbidities placing them at high risk for disease. *Haemophilus influenzae* type B (infants, young children), influenza (H1N1 in pregnant women), meningococcal vaccine
- $\gamma$ -Globulin for hypo- or agammaglobulinemia
- Treat group B strep carriers during labor.
- Regular hand washing, sterile technique for catheter placement, appropriate glove use
- Antibiotic prophylaxis for recommended surgical procedures

## COMMONLY ASSOCIATED CONDITIONS

- Immunologic: neutropenia, HIV, hypo/agammaglobulinemia, complement deficiency, splenectomy, immunosuppressants (corticosteroids, chemotherapy, TNF- $\alpha$  antagonists)
- Diabetes, alcoholism, malignancy, cirrhosis, burns, multiple trauma, IV drug abuse, malnutrition

## DIAGNOSIS

### HISTORY

- Past medical, surgical, social, occupational, and travel history to identify risk factors and potential source
- General symptoms
  - Fever, chills, rigors, myalgias
  - Mental status changes: restlessness, agitation, confusion, delirium, lethargy, stupor, coma
- Specific symptoms (relative to primary source)
  - Respiratory: cough, sputum production, dyspnea, pleuritic chest pain
  - Urinary: dysuria, frequency, urgency, flank pain

- Intra-abdominal: nausea, vomiting, diarrhea, constipation, abdominal pain
- CNS: stiff neck, headache, photophobia, focal neurologic signs

## *PHYSICAL EXAM*

- Assess vital signs: hyper/hypothermia, tachycardia, tachypnea, hypotension
- Signs of poor perfusion: central venous hypoxia, delayed capillary refill, cyanosis, mottled skin
- Signs of target organ involvement: jaundice, skin lesions (erythema, petechiae, embolic lesions, purpura)

## *DIFFERENTIAL DIAGNOSIS*

- Bacteremia without sepsis
- Viral, rickettsial, spirochetal, and protozoal diseases
- Collagen vascular diseases, vasculitides, pancreatitis, myocardial infarction, CHF, pulmonary embolism, thrombotic thrombocytopenic purpura (TTP), hemolytic uremic syndrome (HUS), thyrotoxicosis, adrenal insufficiency, poisoning, drug reaction

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Two sets of blood cultures to document presence of bacteremia (not required for diagnosis; 50% of blood cultures are negative in severe sepsis/septic shock). Obtain cultures before antibiotic therapy. Do not delay the start of antibiotic therapy (1)[B].
- Cultures/Gram stains from potential sites of infection (sputum, urine, pleural fluid, ascites, CSF, wound)
- CBC with differential, CRP, coagulation profile, comprehensive metabolic profile, lactic acid level, arterial blood gas, urinalysis
- Radiographic studies (plain films, ultrasound, CT, or MRI) to confirm source of infection

### *Diagnostic Procedures/Other*

- Aspiration, biopsy, and/or drainage of potentially infected body sites (pleural cavity, peritoneal cavity, biliary tree, CSF, abscess). Interventional radiology techniques to aid in specimen collection as needed
- Echocardiogram if concern for endocarditis

## Test Interpretation

- Common findings: leukocytosis, bandemia (>10%), hyperglycemia, metabolic acidosis, mild hyperbilirubinemia, hypoxemia, respiratory alkalosis, proteinuria
- Less common findings (more severe disease): leukopenia, anemia, thrombocytopenia, coagulopathy, azotemia, hypoglycemia, acidosis

## TREATMENT

### GENERAL MEASURES

- Assess oxygenation and supplement as needed. Intubate for respiratory failure.
- Invasive monitoring for management of hemodynamic instability using goal-directed therapy.

P.961

- Adequate volume resuscitation (30 mL/kg crystalloid for hypotension) within 3 hours of presentation and vasopressors for refractory hypotension (within 6 hours of presentation).

Targets are:

- Central venous pressure (CVP) 8 to 12 mm Hg, MAP  $\geq$ 65 mm Hg, urine output  $\geq$ 0.5 mL/kg/hr (1)[A]
- Central/mixed venous O<sub>2</sub> saturation  $\geq$ 70%/65%
  - If goals not met with fluid resuscitation and/or vasopressor, transfuse PRBCs to achieve hematocrit >30%; if still <70%, add dobutamine (1)[C].
- Identify source of infection and remove septic foci:
  - Early surgical consultation for acute abdomen, empyema, necrotizing fasciitis
  - Interventional radiology consultation for guided drainage
- Transfuse PRBCs, platelets, and/or fresh frozen plasma for coagulopathic complications or in association with planned procedures.
  - Transfuse PRBC if Hgb <7.0 to target Hgb of 7.0 to 9.9 g/dL in absence of tissue hypoperfusion, ischemic coronary artery disease, or acute hemorrhage (1)[B]
- Stress ulcer and DVT prophylaxis (1)[B]
- Glucose control ( $\leq$ 180 mg/dL) (1)[A]

### MEDICATION

## First Line

- Fluid management
  - Initial therapy: 30 mL/kg of crystalloids (1)[B]
  - Consider adding albumin for patients requiring large volumes of crystalloid (1)[C],(3)[B].
- Vasopressors
  - Norepinephrine 0.01 to 3  $\mu\text{g}/\text{kg}/\text{min}$  (1,4)[B].
  - Low-dose dopamine for renal protection is not recommended (1)[C].
- Initiate broad-spectrum antibiotic within an hour of recognizing severe sepsis or septic shock (1,4)[A]:
  - Adult (*Pseudomonas* not suspected): vancomycin (loading dose 25 mg/kg) + Gram-negative coverage (3rd-generation cephalosporin,  $\beta$ -lactam/ $\beta$ -lactamase inhibitor, or carbapenem)
  - Adult (*Pseudomonas* suspected): vancomycin + two agents aimed at resistant Gram-negative bacteria ceftazidime/cefepime/carbapenem/piperacillin-tazobactam + either fluoroquinolone (ciprofloxacin) *or* aminoglycoside (gentamicin/amikacin) depending on local hospital sensitivities
  - Nonimmunocompromised child: 3rd-generation cephalosporin
  - Neonate (<7 days old): ampicillin and gentamicin (5)[B]
  - Consider narrowing antibiotic regimen at 48 to 72 hours based on culture results. Anticipate antibiotic course to last 7 to 10 days (1)[B].
- Antifungals if fungal infection suspected: long-term antibiotic use, TPN, GI surgery
  - Adjuvant intravenous immunoglobulins (IVIGs) may reduce mortality in adults (6)[B].

### ALERT

- Possible interactions
  - Aminoglycosides: increase in nephrotoxicity with enflurane, cisplatin, and possibly vancomycin; ototoxicity with loop diuretics; paralysis with neuromuscular-blocking agents
  - Adjust doses for renal and/or hepatic impairment.
- The European Society of Intensive Care Medicine statement in critically ill patients
  - Hydroxyethyl starches (HESs) with MW  $\geq$  200 kDA and/or degree of

substitution  $>0.4$  are not recommended in severe septic patients (1)[C].

- Hyperoncotic solutions should not be used in fluid resuscitation.

## *Pregnancy Considerations*

*&bgr;*-Lactam antibiotics, macrolides, and metronidazole generally are considered safe.

## *Second Line*

- Vasopressors: epinephrine, vasopressin
- Consider IV hydrocortisone 200 mg per day if the patient is poorly responsive to both IV fluid resuscitation and vasopressors (1)[C].
- Inotropic therapy with dobutamine may benefit patients with myocardial dysfunction or ongoing hypoperfusion despite adequate intravascular volume and MAP (1)[C].

## *ADDITIONAL THERAPIES*

Intermittent hemodialysis or continuous veno-venous hemofiltration for renal failure

## *SURGERY/OTHER PROCEDURES*

Debride necrotic tissues: Drain or remove abscesses or other foci of infection.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

ICU care

### *IV Fluids*

Aggressive fluid resuscitation with normal saline can result in nongap metabolic acidosis. Not likely with lactated Ringer solution.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- Place arterial line and central venous catheter in unstable patients
- Chem-7 and CBC daily; lactate, mixed venous oxygen saturation q2-4h in initial resuscitation

period, and daily INR/PTT if DIC is a concern.

- Follow antibiotic drug levels (vancomycin, gentamicin).
- Foley catheter placement to monitor urine output

## DIET

NPO if intubation considered; otherwise, enteral feeds are preferred to preserve GI mucosal integrity (1)[C].

## PATIENT EDUCATION

[www.nlm.nih.gov/medlineplus/sepsis.html](http://www.nlm.nih.gov/medlineplus/sepsis.html)

## PROGNOSIS

Mortality is 10-50% overall. Poor prognostic factors include the inability to mount a fever ( $>40^{\circ}\text{C}$ ), nonurinary source of infection, nosocomial infection, inappropriate antibiotic coverage, and certain comorbidities (AIDS, cancer, immunosuppression).

## COMPLICATIONS

GI hemorrhage, DIC, hyperglycemia, de novo embolic foci of infection, ARDS, multiorgan failure, death

## Codes

**&NA;**

### ICD10

- A41.9 Sepsis, unspecified organism
- R65.10 SIRS of non-infectious origin w/o acute organ dysfunction
- R65.20 Severe sepsis without septic shock

## Clinical Pearls

**&NA;**

- Treat sepsis aggressively with fluid support (with hemodynamic monitoring and pressor support if necessary) early use of broad-spectrum antimicrobial therapy and removal/drainage of foci of infection.
- Despite aggressive treatment, overall mortality is high (10-50%) in patients with severe

sepsis/septic shock.

# Serotonin Syndrome

Neela Bhajandas, PharmD

Michael C. Barros, PharmD, BCPS, BCACP

Paul N. Williams, MD, FACP

## BASICS

### DESCRIPTION

- A potentially life-threatening adverse drug reaction that results from excessive stimulation of peripheral and CNS serotonergic receptors
- It is a concentration-dependent toxicity that can develop in any individual who has ingested drug combinations that synergistically increase synaptic 5-HT.
- Serotonin toxicity occurs in three main settings: (i) therapeutic drug use, which often results in mild to moderate symptoms; (ii) intentional overdose of a single serotonergic agent, which typically leads to moderate symptoms; and (iii) as the result of a drug interaction between numerous serotonergic agents (most commonly, selective serotonin reuptake inhibitors [SSRIs] and monoamine oxidase inhibitors [MAOIs]), most often associated with severe serotonin toxicity.
- Classically characterized by a triad of symptoms that include mental status change, neuromuscular abnormalities, and autonomic hyperactivity
- Onset is usually within 24 hours with 60% of cases occurring within 6 hours of exposure to, or change in, dosing of a serotonergic agent. Rarely, cases have been reported weeks after discontinuation of serotonergic agents.

### *Geriatric Considerations*

Elderly are at increased risk given use of multiple meds.

### *Pediatric Considerations*

- Serotonin syndrome has similar manifestations in children and adults.
- General management is unchanged in children, other than medication dosing.

### *Pregnancy Considerations*

- 3rd-trimester exposure to SSRIs has been associated with transient neonatal complications that may reflect either acute drug withdrawal or serotonergic toxicity.
- Symptoms in neonates may include tremors, increased muscle tone, jitteriness, shivering, feeding/digestive disturbances, irritability, agitation, sleep disturbances, increased reflexes, excessive crying, and respiratory disturbances.

## *EPIDEMIOLOGY*

Seen in about 14-16% of SSRI overdose patients

### *Incidence*

- In 2008, there were 106,336 adverse events reported with antidepressant use including 28 deaths. Most of these were associated with SSRIs, either alone or in combination with other drugs. SSRIs alone were responsible for adverse events in 18.8% of cases, with 55.7% due to intentional causes, 39.5% unintentional, and remainder of causes unknown. Of patients reporting adverse effects with SSRIs, 46.6% had symptoms requiring hospitalization, and significant toxic effects occurred in 90 patients with 2 resultant deaths (1)[A].
- The incidence of serotonin syndrome is rising because serotonergic agents are increasingly used in clinical practice and in combination with other serotonergic agents.
- Predominant age: affects all age groups
- Predominant sex: male = female

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- The result of excessive stimulation in peripheral and CNS serotonergic receptors
- Risk is mediated in a dose-related manner to the action of 5-HT/5-HT agonists on 5HT-1a and/or 5HT-2a receptors. The development mechanism of the syndrome is unknown.
- It is hypothesized that the degree of serotonin elevation in blood plasma has to be 10-15% times above baseline levels to result in serotonin toxicity (2)[A].
- A number of drugs are associated with the serotonin syndrome, which usually involves combination with an SSRI. These include SSRIs (e.g., citalopram, escitalopram, fluoxetine, fluvoxamine, paroxetine, sertraline); MAOIs; SNRIs (duloxetine, venlafaxine, desvenlafaxine); tricyclic antidepressants (e.g., amitriptyline); other antidepressants (buspirone, nefazodone, trazodone); lithium; triptans; anticonvulsants (Depakote); analgesics (fentanyl, meperidine, pentazocine, tramadol); antibiotics (linezolid [weak MAOI], ritonavir); over-the-counter (OTC) cough medications (dextromethorphan); some antipsychotics (risperidone, olanzapine); antiemetics (ondansetron, granisetron); other medications, such as metoclopramide, cyclobenzaprine, L-dopa; dietary supplements (tryptophan); herbal supplements (St. John's

wort, nutmeg); methylene blue; and drugs of abuse (e.g., methylenedioxymethamphetamine [MDMA], cocaine, D-lysergic acid diethylamide [LSD], and amphetamine).

- Initially, patients can develop a peripheral tremor, confusion, and ataxia; systemic signs are next (e.g., agitation, diaphoresis, hyperreflexia, and shivering). If it worsens, the severe signs of fever, jerking, and diarrhea may develop. Serotonin syndrome can last from hours to days after the offending agents are stopped and supportive care is initiated.
- Drug interactions are most often the cause of severe cases of serotonin syndrome. Many of the same classes of medications listed earlier are involved, especially MAOIs (including linezolid) with SSRIs.

## Genetics

Unknown

## RISK FACTORS

- Serotonergic agents
- Reported following ingestion of a single agent. However, the greatest number of adverse events has been shown to be associated with SSRIs in combination with other substances, and the combination of SSRIs and MAOIs carries the greatest risk for developing serotonin toxicity.

## GENERAL PREVENTION

- Consider drug-drug interactions when a multidrug regimen is required and avoid if possible.
- Caution patients about taking SSRIs with OTC medications (e.g., dextromethorphan) or herbal supplements (e.g., St. John's wort) prior to consulting a physician.
- Clinician education
- Continual improvement in use of health information technology

## DIAGNOSIS

- Serotonin syndrome is a clinical diagnosis.
- Epidemiologic data suggest that up to 85% of practitioners are unaware of serotonin syndrome.
- *Hunter Toxicity Criteria Decision Rules* aid in the diagnosis of clinically significant serotonin toxicity (sensitivity, 84%; specificity, 97%).
- To fulfill Hunter criteria, a patient must have taken a serotonergic agent and have one of the following:

- Spontaneous clonus
- Inducible clonus plus agitation/diaphoresis
- Ocular clonus plus agitation/diaphoresis
- Tremor and hyperreflexia
- Hypertonia
- Temperature >38°C plus ocular clonus/inducible clonus (3)[A]

## HISTORY

- Obtain a thorough drug history, including prescription medications, OTC remedies, dietary supplements, herbal supplements, and illicit drugs. Ask about dose, formulation, and recent changes.
- Address possibility of drug overdose, and obtain collateral information if intentional overdose is suspected.
- Elicit description of symptoms, including their onset and progression.

## PHYSICAL EXAM

- Vital signs: tachycardia, hypertension, and hyperthermia (severe cases)
- Neuromuscular findings (seen in over half of patients with serotonin syndrome)
  - Hyperreflexia (greater in lower extremities)
  - Clonus (involuntary muscle contractions, most commonly tested by flexing foot upward rapidly; includes ocular)
  - Myoclonus (greater in lower extremities)
  - Tremor (greater in lower extremities)
  - Hypertonia
  - Bilateral Babinski sign
  - Akathisia
  - Tonic-clonic seizures (severe cases)
  - Autonomic signs
    - Diaphoresis
    - Mydriasis

Flushing

- Dry mucous membranes
- Vomiting, diarrhea, increased bowel sounds
- Mental status changes: anxiety, disorientation, delirium (4)[A]
- Severe cases have led to altered level of consciousness, rhabdomyolysis, metabolic acidosis, and disseminated intravascular coagulation (DIC).

## ***DIFFERENTIAL DIAGNOSIS***

- Neuroleptic malignant syndrome (NMS)
- Anticholinergic fever (e.g., benztropine, diphenhydramine, oxybutynin, nifedipine, famotidine, atropine, scopolamine; plant poisoning from belladonna/Ödeadly nightshade,Ó datura, henbane, mandrake, brugmansia)
- Malignant hyperthermia
- Heat stroke

---

P.963

- CNS infection (meningitis, encephalitis)
- Sympathomimetic toxicity
- Nonconvulsive seizures
- Hyperthyroidism
- Tetanus
- Acute baclofen withdrawal

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Serum serotonin levels do not correlate with clinical findings.
- Nonspecific lab findings that may develop include the following:
  - Elevated WBC count
  - Elevated creatine phosphokinase (CK or CPK)
  - Decreased serum bicarbonate
  - Elevated hepatic transaminases
- In severe cases, the following complications may develop:

- DIC
- Metabolic acidosis
- Rhabdomyolysis
- Renal failure
- Myoglobinuria
- Acute respiratory distress syndrome (ARDS) (4)[A]

## TREATMENT

- Discontinue all serotonergic agents.
- Supportive care is the mainstay of therapy. This includes administration of oxygen and aggressive IV fluids, continuous cardiac monitoring, and correction of vital signs.
  - Benzodiazepines may be effective for the management of agitation in patients with serotonin syndrome.
  - Administration of serotonin antagonists: Cyproheptadine (histamine and serotonin antagonist) may be useful if supportive measures and sedation (benzodiazepines) are unable to control agitation and correct vital signs.
- Mild cases (afebrile, tachycardia, shivering, diaphoresis, mydriasis, hyperreflexia, intermittent tremor or myoclonus)
  - Discontinue precipitating agent(s).
  - Supportive care
  - Sedation
- Moderate cases (temperature  $>38^{\circ}\text{C}$ , autonomic instability, mydriasis, hyperactive bowel sounds, diarrhea, diaphoresis, ocular clonus, hyperreflexia, tremor, mild agitation, or hypervigilance)
  - Discontinue precipitating agent(s).
  - Supportive care
  - Sedation
  - Aggressive treatment of autonomic instability
  - Treatment with cyproheptadine should be initiated if agitation and vital sign abnormalities are unimproved with benzodiazepines and supportive care.

- Hypotension from MAOI interactions should be treated with low doses of direct-acting sympathomimetics (e.g., norepinephrine, phenylephrine, epinephrine); indirect serotonin agonists, such as dopamine, should be avoided.
- Severe hypertension and tachycardia should be treated with short-acting agents, such as nitroprusside or esmolol.
- Avoid use of longer acting agents, such as propranolol.
- Severe cases (temperature >41.1°C, autonomic instability, delirium, muscular rigidity, and hypertonicity)
  - Discontinue precipitating agent(s).
  - Immediate sedation
  - Endotracheal intubation as clinically indicated
  - Paralysis as clinically indicated (maintained with nondepolarizing continuous paralytic agents such as vecuronium, cisatracurium, rocuronium)
  - Antipyretic medications are not effective (4)[A]; the increased body temperature is due to muscle activity, not an alteration in the hypothalamic set point.

## **MEDICATION**

- Activated charcoal: may be used in patients who intentionally overdose on serotonergic agents (3)[A]
- Benzodiazepines: may be used to manage agitation in serotonin syndrome and also may correct mild increases in BP and heart rate. Use with caution in patients with delirium, given the known paradoxical effect of exacerbating delirium.
- Cyproheptadine (Periactin): Consider use if benzodiazepines and supportive measures are unable to control agitation and correct vital signs:
  - Adults: initial dose 12 mg PO (can also be crushed and given via nasogastric [NG] tube) followed by 2 mg q2h until clinical response observed; 12 to 32 mg of drug may be required in a 24-hour period.
  - Children
    - <2 years: 0.06 mg/kg q6h
    - 2 to 6 years: 2 mg q6h
    - 7 to 14 years: 4 mg q6h
  - Unlikely to be effective in patients who have received activated charcoal.

- Use of antipsychotics with 5-HT<sub>2A</sub> antagonist activity, such as olanzapine and chlorpromazine, is not recommended (4)[A].

## *ISSUES FOR REFERRAL*

- Psychiatry: for assistance with medication management and follow-up care (inpatient psychiatric care vs. outpatient psychiatric follow-up)
- Toxicology/clinical pharmacology service
- Poison control center

## *INPATIENT CONSIDERATIONS*

Patients with known/suspected serotonin syndrome should be admitted to a medical inpatient unit for observation.

### *Discharge Criteria*

- Mental status has returned to baseline.
- Stable vital signs
- No increase in clonus
- Close patient follow-up is ensured.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- In mild cases of serotonin toxicity, address risks and benefits of restarting offending agents. Serotonergic medications need to be titrated slowly, and patients must have close outpatient follow-up with physician.
- If patient developed severe serotonin syndrome, the offending agent should likely not be resumed unless precipitant for serotonin syndrome is found (e.g., combination with another serotonin agonist); the patient can be carefully monitored, or there is clear benefit versus risk of restarting the medication.

### *PROGNOSIS*

- Generally favorable with early recognition of the syndrome and prompt initiation of treatment
- Most cases resolve within 24 hours of discontinuation of serotonergic agents; this can be longer depending on the drug's half-life:

- MAOIs can result in toxicity for several days.
- SSRIs can result in toxicity for up to several weeks after discontinuation.
- ICU admission is often indicated in severe cases.

## COMPLICATIONS

- Adverse outcomes, including death, are usually the consequence of poorly treated hyperthermia.
- Nonhyperthermic patients who survive typically do not have long-term sequelae.

**Codes**

&NA;

# ICD10

G25.79 Other drug induced movement disorders

## Clinical Pearls

**&NA;**

Consider serotonin syndrome in patients with recent use of a serotonergic agent (particularly if multiple proserotonergic agents are involved) presenting with unexplained tachycardia, hypertension, hyperthermia, clonus, hyperreflexia, and change in mental status.

# Sexual Dysfunction in Women

Amanda M. Carnes, MD

Lisa M. Harris, DO

## BASICS

- Very common: ÷40% of women surveyed in the United States have sexual concerns.
- May present as a lack of sexual desire, impaired arousal, pain with sexual activity, or inability to achieve orgasm, and may be lifelong or acquired

## DESCRIPTION

- Female sexual interest or arousal disorder—lack of or significantly reduced sexual interest or arousal as manifested by three of the following:
  - Absent or reduced interest in sexual activity
  - Absent or reduced sexual or erotic thoughts or fantasies
  - No or reduced initiation of sexual activity and unreceptive to partner's attempts to initiate
  - Absent or reduced sexual excitement or pleasure during sexual activity in almost all (75-100%) of sexual encounters
  - Absent or reduced sexual interest or arousal in response to any internal or external sexual or erotic cues
  - Absent or reduced genital or nongenital sensation during sexual activity in almost all (75-100%) of sexual encounters
- Female orgasmic disorder—presence of either of the following in almost all (75-100%) occasions of sexual activity:
  - Marked delay in, marked infrequency of, or absence of orgasm
  - Markedly reduced intensity of orgasmic sensations
- Genitopelvic pain or penetration disorder—persistent or recurrent difficulties with one or more of the following:
  - Vaginal penetration during intercourse
  - Marked vulvovaginal or pelvic pain during intercourse or penetration attempts

- Marked fear or anxiety about vulvovaginal or pelvic pain in anticipation of, during, or because of vaginal penetration
- Marked tensing or tightening of pelvic floor muscles during attempted vaginal penetration

## **ALERT**

- Symptoms must be present for 6 months; cause clinically significant distress or impairment; and not be caused by another condition (psychiatric or medical), substance/medication, relationship distress, or other stressor.
- System(s) affected: nervous; reproductive; genitourinary; psychiatric
- Synonym(s): hypoactive sexual desire disorder; sexual aversion disorder; female sexual arousal disorder; inhibited female orgasm

## **EPIDEMIOLOGY**

In two large studies, approximately 40% of women reported sexual problems.

### *Incidence*

Sexual problems are highest in women aged 45 to 64 years, then declines secondary to changes in sexual-related personal distress.

### *Prevalence*

Low sexual desire is the most common manifestation, followed by difficulty with orgasm, difficulty with arousal, and sexual pain.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

The pathophysiology of sexual dysfunction is complex and multifactorial because it can be the result of any etiology that interferes with the nonlinear model of female sexual response cycle (emotional intimacy, sexual stimuli, psychological factors, and relationship satisfaction).

- Physiologic
  - Prescription medications
    - SSRIs, MAOIs, and TCAs
    - $\beta$ -Blockers, ACE inhibitors, and calcium channel blockers
    - GnRH agonists
    - Injectable progestins
    - Antiepileptics

- Gabapentin
- Endocrine
  - Disorders of the hypothalamic-pituitary-adrenal system, hormonal imbalance/disorders of ovarian function, menopause (surgical or natural)
  - Thyroid disease
  - Diabetes
- Neurologic
  - Spinal cord damage
- Psychologic
  - Maladaptive thoughts/behaviors
  - Interrelational difficulties
  - Body image issues
  - Drug and alcohol abuse
  - Sexual abuse

## ***RISK FACTORS***

- Advancing age/menopause
- Previous sexual trauma
- Lack of knowledge about sexual stimulation and response
- Chronic medical problems
  - Depression, anxiety, chronic pain syndromes, and other psychiatric disorders
  - Cardiovascular disease
  - Endocrine disorders
  - Dermatologic disorders
  - Neurologic disorders
  - Cancer
- Gynecologic issues
  - Childbirth

- Pelvic floor or bladder dysfunction
- Endometriosis
- Uterine fibroids
- Chronic vulvovaginal candidiasis/vaginal infections
- Female genital mutilation
- Relationship factors such as couple discrepancies in expectations and/or cultural backgrounds and attitudes toward sexuality in family of origin
- Medications or substance abuse

## *COMMONLY ASSOCIATED CONDITIONS*

- Marital/relationship discord
- Depression

## **DIAGNOSIS**

- Female sexual dysfunction is diagnosed by utilizing a validated sexual function screening instrument and a structured interview, including detailed medical and sexual history, to confirm diagnosis.
  - Female Sexual Function Index
  - Brief Index of Sexual Functioning for Women
  - Brief Sexual Symptoms Checklist
  - Decreases Sexual Desire Screener
- The diagnosis requires that the sexual problem be recurrent or persistent and cause personal distress rather than be due solely to partner or relationship issues.

## **HISTORY**

- Detailed sexual history (1)[C].
  - Degree of personal distress
  - Lifelong versus acquired problem
  - Situational versus generalized problem
  - Cultural/societal beliefs regarding sexuality
  - History of sexual trauma

- Concerns about safety, pregnancy, or STIs
  - Concerns regarding privacy
- Interpersonal relationship factors
  - Current relationship status
  - Family dysfunction
- Physiologic/biologic history
  - Urinary/anal incontinence
  - Medications (including herbal and OTC)
  - Pregnancy/childbirth history
  - Infertility
  - Menopausal status (natural, surgical, or postchemotherapy)
  - STIs and vaginitis
  - Pelvic surgery, injury, or cancer
  - Chronic pelvic pain
  - Abnormal genital tract bleeding
- Psychologic History
  - Low self-image
  - Anxiety
  - Depression
  - Negative past sexual experiences
  - Substance misuse/abuse

## *PHYSICAL EXAM*

- Most commonly, patients have a normal physical exam (1)[C].
  - Assess for anatomic abnormalities.
  - Assess for scars or evidence of trauma.
  - Assess for vaginal atrophy, adequate estrogenization.
  - Assess for infection.
  - Recognize signs of anxiety, apprehension, and pain during the speculum and pelvic exam.
- General physical exam, signs of chronic disease

## ***DIFFERENTIAL DIAGNOSIS***

- Medication side effects
- Vaginitis
- Decreased vaginal lubrication secondary to hormonal imbalance
- Decreased sensation secondary to nerve injury
- Multiple sclerosis
- Anatomic abnormalities
- Abdominal surgery (which can interfere with pelvic innervation)
- Depression
- Marital dysfunction, including domestic violence
- Pregnancy
- Pseudodyspareunia (use of complaint of pain to distance self from partner)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Laboratory studies are rarely helpful. There are no reliable correlations between serum hormone levels and sexual dysfunction.

### ***Initial Tests (lab, imaging)***

As needed to identify infections and other medical causes (1)[C]

---

P.965

## **TREATMENT**

- Set realistic goals and expectations (2)[C].
- Address underlying medical and psychiatric conditions (3)[C].
- Review basic sex education, sexual response, heterogeneity of normal response, and sexual activity other than intercourse (2,4)[C].
- Education on communication (4)[C]
- Educate on healthy lifestyle, including diet, exercise, sleep, avoidance of tobacco, and reduced alcohol use (2,4)[C].
- Vaginal moisturizers and lubricants (5)[C]
- Cognitive-behavioral therapy (CBT) (individual or couples) to target maladaptive thoughts and

behaviors and to disrupt the dysfunctional cycle (3,4)[C]

- Mindfulness-based CBT (2,4)[C]
- Sex therapy: sensate focus, systematic desensitization exercises, homework exchanging physical touch with partner, or directed masturbation alone (3,4)[C]
- Physical therapy/biofeedback (4)[C]

## **MEDICATION**

Sexual dysfunction is often a multifactorial psychosocial condition. Using medications does not usually address the cause of the problem and can, in some cases, make the condition worse.

- Bupropion (2,4)[C]: adjunct for SSRI-induced sexual dysfunction. Improves sexual arousal and orgasm but not desire. Dose: bupropion SR 150 mg orally once or twice daily.
- Flibanserin (3)[C]: possible improvement in sexual desire. Mechanism of action: 5-HT<sub>1A</sub> agonist and 5-HT<sub>2A</sub> antagonist.
- Estrogen replacement with or without progestins (2,5)[C],(6)[A]: may improve sexual desire, vaginal atrophy, and clitoral sensitivity. Vaginal estrogen therapy is available in cream, vaginal tablet, or ring form.
- Ospemifene (2)[C]: selective estrogen receptor modulator FDA approved for dyspareunia due to vulvo or vaginal atrophy in postmenopausal women. Dose: ospemifene 60 mg orally once daily.
- Testosterone (2,3,4)[C]
  - Use in premenopausal women not supported by data.
  - In naturally or surgically postmenopausal women, adding short-term testosterone to hormone replacement may increase desire.
  - Use >6 months contingent on clear improvement and no adverse effects.
  - Side effects: hirsutism, androgenic alopecia, acne, decreased HDL, liver dysfunction; not FDA approved for sexual dysfunction in women
  - Contraindicated in breast or endometrial cancer, thromboembolic disease, or coronary artery disease
  - Dose: oral methyltestosterone 1.25 to 2.5 mg/day (1/10 of men's dose) or topical (patch, gel)
- DHEA and tissue-selective estrogen complexes (TSECs) (3,4,5)[C]: may improve vaginal atrophy, dryness, and dyspareunia. Not FDA approved. Additional studies needed

PDE-5 inhibitors (4)[C]: not recommended

## ***ISSUES FOR REFERRAL***

Consider referral for CBT, marriage/couples counseling, or sex therapy.

## ***ADDITIONAL THERAPIES***

- Smoking cessation and reduction of alcohol intake
- For childhood trauma: scripting, psychotherapy, cognitive restructuring
- For prescription-drug causes: reduced dosages or change to different medication

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Zestra for Women botanical feminine massage oil: Small trial showed increased arousal, desire, genital sensation, ability to have orgasm, and sexual pleasure.
- Yohimbine: not recommended, potentially dangerous
- Ginseng and St. John's wort: No evidence to support treatment of sexual dysfunction.

## **ONGOING CARE**

### ***DIET***

Weight reduction if overweight or obese

### ***PATIENT EDUCATION***

- American Association of Sex Educators, Counselors, and Therapists: [www.aasect.org](http://www.aasect.org).
- National Women's Health Resource Center: [www.healthywomen.org](http://www.healthywomen.org)
- North American Menopause Society: [www.menopause.org](http://www.menopause.org)
- National Vulvodynia Association: [www.nva.org](http://www.nva.org)

### ***PROGNOSIS***

Lack of desire is most difficult type to treat with <50% success.

## Codes

&NA;

### ICD10

- R37 Sexual dysfunction, unspecified
- F52.0 Hypoactive sexual desire disorder
- N94.1 Dyspareunia

## Clinical Pearls

&NA;

- Female sexual dysfunction is a common, complex, multifactorial problem.
- Usually patients with sexual dysfunction have a normal physical exam.

- Symptoms of sexual dysfunction peak during perimenopause between the ages of 45 and 64 years.
- Several therapies exist for treating sexual dysfunction in women, including behavioral therapy and medications.

# Shoulder Pain

Daniel L. Jones, MD

J. Herbert Stevenson, MD

## BASICS

### DESCRIPTION

- Shoulder pain is common and affects patients of all ages. Causes include acute trauma or overuse during sports and activities of everyday living.
- Age plays an important role in determining the etiology of shoulder pain.
- Onset and characteristics of pain, weakness, mechanism of injury, and functional limitation help guide an accurate diagnose.

### EPIDEMIOLOGY

- Shoulder pain accounts for 16% of all musculoskeletal complaints.
- The lifetime prevalence of shoulder pain is ÷70%.
- Predominant etiology varies with age:
  - <30 years: shoulder instability
  - >30 years: rotator cuff (RTC) disorder
    - 30 to 50 years: tendinopathy
    - 40 to 60 years: partial tear
    - >60 years: full-thickness tear
  - >60 years: glenohumeral osteoarthritis (OA)

### Incidence

The incidence of shoulder pain is 7 to 25 cases/1,000 patients, with a peak incidence in the 4th to 6th decades.

### ETIOLOGY AND PATHOPHYSIOLOGY

Pathology varies with cause:

- Trauma (fracture, dislocation, ligament/tendon tear, acromioclavicular [AC] separation)
- Overuse (RTC pathology, biceps tenosynovitis, bursitis, muscle strain, apophyseal injuries)
  - RTC disorders most commonly result from repetitive overhead activity, leading to RTC impingement with a 3 stage progression:
    - Stage I: tendinopathy
    - Stage II: partial RTC tear
    - Stage III: full-thickness RTC tear
  - Subacromial bursitis can occur with RTC disorders but is rarely an isolated diagnosis.
- Age-related: AC and glenohumeral joint OA, adhesive capsulitis, RTC tear with increasing age; pediatric athletes instability and physeal injuries are more common.
- Rheumatologic (rheumatoid arthritis, polymyalgia rheumatica, fibromyalgia)
- Referred pain (neck, gallbladder)

## *RISK FACTORS*

- Repetitive overhead activity
- Overhead and upper extremity weight-bearing sports (baseball, softball, swimming, tennis, volleyball)
- Weight lifting: AC disorders
- Rapid increases in training frequency or load (often associated with improper technique)
- Muscle weakness or imbalance
- Trauma or fall onto the shoulder
- Diabetes, thyroid disorders, female gender, and age 40 to 60 years are risk factors for adhesive capsulitis.

## *GENERAL PREVENTION*

- Maintain strength and range of motion (ROM).
- Avoid repetitive overhead activities (pitch counts).
- Proper technique (pitching, weight lifting)

# DIAGNOSIS

## HISTORY

- Pain characteristics
  - Superior shoulder pain: AC pathology, trapezius strain
  - Lateral/deltoid pain: RTC pathology (RTC pain typically does not extend past elbow.)
  - Diffuse pain: RTC pathology, adhesive capsulitis, glenohumeral OA
  - Posterior (scapular) pain: scapulothoracic dyskinesis
  - Night pain: RTC pathology (pain laying on affected side), adhesive capsulitis, glenohumeral OA
  - Stiff shoulder: adhesive capsulitis
  - Pain with cross-body activities: AC pathology
  - Pain with abduction/external rotation (reaching behind): shoulder instability
  - Pain with overhead activity: RTC pathology, AC pathology, labrum pathology
  - Pain with turning neck, pain past elbow: cervical pathology
- Mechanism of injury
  - Fall on outstretched hand: traumatic shoulder instability/dislocation
  - Fall directly onto shoulder: AC joint sprain, clavicular fracture
  - Repetitive overhead activity: RTC pathology
- Age
  - Shoulder instability (subluxation, dislocation, multidirectional instability) is the most common cause of shoulder pain in young athletes (<30 years old).
  - RTC disorders are the most common cause of shoulder pain in patients >30 years old. Severity of RTC disorder increases with age.
  - Older patients (>60 years old) commonly have OA.
  - Trauma in a young person <40 years is more commonly associated with dislocation/subluxation. In patients >40 years, trauma is more commonly associated with RTC tear.

## PHYSICAL EXAM

- Observe face and shoulder movements as patient disrobes, moves arm, and shakes hand.
- Inspect for malalignment, muscle atrophy, asymmetry, erythema, ecchymosis and swelling.

Scapular winging suggests long thoracic nerve or muscular (trapezius, serratus anterior) dysfunction. Prominent scapular spine with scalloped infraspinatus fossa suggests infraspinatus atrophy.

- Palpate for tenderness, warmth, bony step-offs.
- Evaluate active and passive ROM and flexibility:
  - Decreased active AND passive ROM are more common with adhesive capsulitis.
  - Mildly decreased active and/or passive ROM may also indicate glenohumeral OA.
- Decreased active, full passive ROM: RTC pathology
- Evaluate for muscle strength including grip, biceps, triceps, and deltoid. Test RTC strength: supraspinatus (empty can test), infraspinatus/teres minor (resisted external rotation, external lag test), subscapularis (lift-off test, belly press, resisted internal rotation). Pain with RTC strength testing indicates RTC pathology. Weakness could suggest tear.
- Special tests
  - Neer, Hawkin tests: RTC impingement
  - Drop-arm test: RTC tear
  - Cross-arm adduction test: AC joint arthritis
  - Speed, Yergason tests: biceps tendinopathy
  - Apprehension, relocation test: anterior glenohumeral joint instability
  - Sulcus sign: inferior glenohumeral joint instability
  - O'Brien, clunk test: labral pathology
  - Spurling test: cervical pathology

## *DIFFERENTIAL DIAGNOSIS*

- Fracture (clavicle, humerus, scapula), contusion
- RTC disorder: impingement, tear, calcific tendonitis
- Subacromial bursitis
- Scapulothoracic dyskinesis
- AC joint pathology (AC separation/OA, osteolysis)
- Biceps tenosynovitis or tear
- Acromial apophysitis or os acromiale

- Glenohumeral joint OA
- Glenohumeral joint instability (acute dislocation or chronic multidirectional instability)
- Adhesive capsulitis
- Labral tear or associated bony pathology
- Muscle strain (trapezius, deltoid, biceps)
- Cervical radiculopathy
- Other: autoimmune, rheumatologic, referred pain, septic joint (biliary/splenic, cardiac, pneumonia/lung mass)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Shoulder pain can be accurately diagnosed with a careful history and physical exam:
  - Adults with nontraumatic shoulder pain of <4 weeks duration may not require initial imaging.
- History of significant trauma, prolonged symptoms, or red flags (older age, fever, rest pain) suggest need for imaging.
- Plain radiographs are first-line:
  - Assess for fracture, degenerative changes, signs of dislocation (Bankart, Hill-Sachs deformity), signs of large RTC tear (sclerosis, proximal migration of humeral head), anatomic deformities contributing to impingement, and occult tumor.
  - Standard views: anteroposterior, scapular Y, axillary

---

P.967

- EMG study of the upper extremity may help differentiate referred cervical pain from a primary shoulder disorder.
- Obtain ECG if any suspicion for cardiac etiology.
- Serologic tests if autoimmune etiology is suspected.

## **Follow-Up Tests & Special Considerations**

- CT scan can rule out occult fracture.
- MRI is gold standard for noninvasive soft tissue imaging, including RTC, biceps tendon.
- MR arthrogram may be necessary to assess for labral tears or small/partial RTC tears.
- Ultrasound (US) helps assess RTC tears, biceps tendinopathies, and AC joint disorders.

## *Diagnostic Procedures/Other*

Diagnostic arthroscopy after noninterventional means have been exhausted if structural injury is suspected.

## *Test Interpretation*

Depends on underlying diagnosis

- Tendinosis rather than tendonitis is common with stage I impingement.
- Capsular scarring is the hallmark of adhesive capsulitis.
- RTC tendon calcifications with calcific tendonitis

## **TREATMENT**

Treatment is based on underlying diagnosis. In general, conservative therapy includes activity modification, analgesics, and/or anti-inflammatory medicines in association with appropriate rehabilitative programs.

## *MEDICATION*

### *First Line*

- Analgesics and anti-inflammatory medications for symptomatic relief:
  - Ibuprofen: 200 to 800 mg TID
  - Naproxen: 250 to 500 mg BID
  - Acetaminophen: not to exceed 3 g/day
- Corticosteroid injections (subacromial, glenohumeral, AC, subscapular bursa) acutely relieve pain due to RTC pathology, adhesive capsulitis, OA, or scapulothoracic dyskinesis (1)[A]. This improves ability to engage in rehabilitative activities.
- US guidance improves accuracy of anatomic placement of corticosteroid injections (2)[A].

## *ISSUES FOR REFERRAL*

Refer if etiology remains unclear, patient is not responsive to conservative care, for complicated or displaced fractures, or full thickness RTC tears >1 cm acute or chronic in patients <65 years old or any tear with significant changes in functional status. These tears have a high rate of progression, fatty infiltration, or retraction with nonoperative care (3).

## ***ADDITIONAL THERAPIES***

- Physical therapy benefits persistent RTC disorders, adhesive capsulitis, and shoulder instability.
- Physical therapy/exercise may improve nonspecific shoulder pain, but it does not generally improve ROM or function (4)[A].
- Manual manipulative therapy (MMT) by chiropractors, osteopathic physicians, or physical therapists improves pain with adhesive capsulitis, RTC, and soft tissue disorders (5)[A]. MMT is generally less effective than glucocorticoid injections at 6 weeks with similar long-term outcomes in adhesive capsulitis (6)[A].

## ***SURGERY/OTHER PROCEDURES***

- Surgery is necessary for shoulder pain caused by acute displaced fractures, large RTC tears (criteria as above), shoulder dislocation in patients <20 years of age. Surgery may be necessary for shoulder pain unresponsive to conservative measures >3 to 6 months. Surgery is not more effective than active nonsurgical treatment in impingement syndrome (7)[A].
- Platelet-rich therapies need more conclusive evidence before routine use in treatment of MSK soft tissue injuries (8)[A].

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Acupuncture may help with acute shoulder pain. There is no conclusive evidence for the effectiveness of acupuncture.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Limit overhead activity to reduce impingement symptoms.

### ***PATIENT EDUCATION***

Refer to specific diagnosis for shoulder pain.

### ***PROGNOSIS***

Shoulder pain generally has a favorable outcome with conservative care, but recovery can be slow, with 40-50% of patients complaining of persistent pain or recurrence at 12 months.

## Codes

**&NA;**

### ICD10

- M25.519 Pain in unspecified shoulder
- S43.429A Sprain of unspecified rotator cuff capsule, init encntr
- M19.019 Primary osteoarthritis, unspecified shoulder

## Clinical Pearls

**&NA;**

- RTC disorders (tendinopathy, tears) are the most common cause of shoulder pain in individuals >30 years of age.
- Shoulder instability (acute dislocation/subluxation or chronic instability) is the most common source of shoulder pain in individuals <30 years of age.
- Patients with diabetes are at increased risk for adhesive capsulitis.

# Sinusitis

Chirag N. Shah, MD

Patrick J. Rogers, DO

## BASICS

### DESCRIPTION

- Acute sinusitis is a symptomatic inflammation of <sup>31</sup> paranasal sinuses of <4 weeks' duration resulting from impaired drainage and retained secretions accompanied by obstruction, facial pain/pressure/fullness, or both. Because rhinitis and sinusitis usually coexist, Rhinosinusitis<sup>3</sup> is the preferred term.
- Disease is subacute when symptomatic for 4 to 12 weeks, recurrent acute when <sup>34</sup> annual episodes without persistent symptoms in between and chronic when symptomatic for >12 weeks.
- Uncomplicated rhinosinusitis has no extension of inflammation beyond paranasal sinuses and nasal cavity.
- System(s) affected: head/eyes/ears/nose/throat (HEENT), pulmonary

### EPIDEMIOLOGY

- Affects one in eight adults accounting for >30 million individuals in the United States each year diagnosed with rhinosinusitis
- Diagnosis of acute bacterial rhinosinusitis remains the fifth leading reason for prescribing antibiotics.
- 0.5-2% of viral rhinosinusitis episodes have a bacterial superinfection.
- Viral cause in 90-98% of cases

### Incidence

Incidence is highest in early fall through early spring (related to incidence of viral upper respiratory infection [URI]). Adults have two to three viral URIs per year; 90% of these colds are accompanied by viral rhinosinusitis. It is the fifth most common diagnosis made during family physician visits.

# ETIOLOGY AND PATHOPHYSIOLOGY

- Important features
  - Inflammation and edema of the sinus mucosa
  - Obstruction of the sinus ostia
  - Impaired mucociliary clearance
- Secretions that are not cleared become hospitable to bacterial growth.
- Inflammatory response (neutrophil influx and release of cytokines) damages mucosal surfaces.
- Viral: vast majority of cases (rhinovirus; influenza A and B; parainfluenza virus; respiratory syncytial; adeno-, corona-, and enteroviruses)
- Bacterial (complicates 0.5-2% of viral cases)
  - More likely if symptoms worsen within 5 to 6 days after initial improvement
  - No improvement within 10 days of symptom onset
  - >3 to 4 days of fever >102°F and facial pain and purulent nasal discharge
  - *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Moraxella catarrhalis* are the most common bacterial pathogens.
  - Often overdiagnosed, which leads to overuse of and increasing resistance to antibiotics
  - Methicillin-resistant *Staphylococcus aureus* present in 0-15.9% of patients.
- Fungal: seen in immunocompromised hosts (uncontrolled diabetes, neutropenia, use of corticosteroids) or as a nosocomial infection

## Genetics

No known genetic pattern

## RISK FACTORS

- Viral URI
- Allergic rhinitis
- Asthma
- Cigarette smoking
- Dental infections and procedures
- Anatomic variations

- Tonsillar and adenoid hypertrophy
- Turbinate hypertrophy, nasal polyps
- Cleft palate
- Immunodeficiency (e.g., HIV)
- Cystic fibrosis (CF)

## GENERAL PREVENTION

- Hand washing to prevent transmission of viral infection
- Childhood vaccinations up to date
- Avoid close contacts with symptomatic individuals.
- Avoid smoking and exposure to second hand smoke.

## DIAGNOSIS

- History and physical exam suggest and establish the diagnosis but are rarely helpful in distinguishing bacterial from viral causes.
- Use a constellation of symptoms rather than a particular sign or symptom in diagnosis.

## HISTORY

- Symptoms somewhat predictive of bacterial sinusitis (1)[C]
  - Worsening of symptoms >5 to 6 days after initial improvement
  - Persistent symptoms for 10 days
  - Persistent purulent nasal discharge
  - Unilateral upper tooth or facial pain
  - Unilateral maxillary sinus tenderness
  - Fever
- Associated symptoms
  - Headache
  - Nasal congestion
  - Retro-orbital pain
  - Otagia
  - Hyposomia

## Halitosis

- Chronic cough
- Symptoms requiring urgent attention
  - Visual disturbances, especially diplopia
  - Periorbital swelling or erythema
  - Altered mental status

## *PHYSICAL EXAM*

- Fever
- Edema and erythema of nasal mucosa
- Purulent discharge
- Tenderness to palpation over sinus(es)
- Pain localized to sinuses when bending forward
- Transillumination of the sinuses may confirm fluid in sinuses (helpful if asymmetric; not helpful if symmetric exam).

## *Pediatric Considerations*

- Sinuses are not fully developed until age 20 years. Maxillary and ethmoid sinuses, although small, are present from birth.
- Because children have an average of six to eight colds per year, they are at risk for developing sinusitis.
- Diagnosis can be more difficult than in adults because symptoms are often more subtle.

## *DIFFERENTIAL DIAGNOSIS*

- Dental disease
- CF
- Wegener granulomatosis
- HIV infection
- Kartagener syndrome
- Neoplasm
- Headache, tension, or migraine

## DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic tests are not routinely recommended; no diagnostic tests can adequately differentiate between viral and bacterial rhinosinusitis (2)[C].

- None indicated in routine evaluation
- Routine use of sinus radiography discouraged because of the following:
  - 33 clinical findings have similar diagnostic accuracy as imaging.
  - Imaging does not distinguish viral from bacterial etiology.
- Limited coronal CT scan can be useful in recurrent infection or failure to respond to medical therapy.

### *Diagnostic Procedures/Other*

Sinus CT if signs suggest extrasinus involvement or to evaluate chronic rhinosinusitis

### *Test Interpretation*

- Inflammation, edema, thickened mucosa
- Impaired ciliary function
- Metaplasia of ciliated columnar cells
- Relative acidosis and hypoxia within sinuses
- Polyps

## TREATMENT

Most cases resolve with supportive care (treating pain, nasal symptoms). Antibiotics should be reserved for symptoms that persist >10 days, onset with severe symptoms (high fever, purulent nasal discharge, facial pain) for at least 3 to 4 consecutive days, or worsening signs/symptoms that were initially improving (1,2)[C].

## GENERAL MEASURES

- Hydration
- Steam inhalation 20 to 30 minutes TID
- Saline irrigation (Neti pot) or nose drops
- Sleep with head of bed elevated.

- Avoid exposure to cigarette smoke or fumes.
- Avoid caffeine and alcohol.
- Antibiotics are indicated only when findings suggest bacterial infection.
- Analgesics, NSAIDs
- Acute viral sinusitis is self-limiting; antibiotics should not be used.

## MEDICATION

### First Line

- Decongestants
  - Pseudoephedrine HCl
  - Phenylephrine nasal spray (limited use)
  - Oxymetazoline nasal spray (e.g., Afrin) (not to be used >3 days)
- Analgesics
  - Acetaminophen
  - Aspirin
  - NSAIDs

---

P.969

- Antibiotics
  - Antibiotics have a slight advantage over placebo at 7 to 14 days (3)[A], yet most improve without therapy.
  - Reserve antibiotic use for patients with moderate to severe disease.
  - Choice should be based on understanding of antibiotic resistance in the community.
  - Infectious Disease Society of America recommends the following (1)[C]:
    - Start antibiotics as soon as clinical diagnosis of acute bacterial sinusitis is made.
    - Use amoxicillin-clavulanate rather than amoxicillin alone.
    - Amoxicillin-clavulanate 875/125 mg q12h; 2 g orally BID in geographic regions with high rates of resistant *S. pneumoniae*
    - Doxycycline: 100 mg PO BID an alternative to amoxicillin-clavulanate for initial therapy (adults only)

- Trimethoprim-sulfamethoxazole (TMP/SMX) and 3rd generation cephalosporins not recommended due to high rate of resistance (1)[C]
- Treat for 5 to 7 days in adults if uncomplicated bacterial rhinosinusitis (IDSA low-moderate-quality evidence). Treat for 10 to 14 days in children if uncomplicated bacterial rhinosinusitis (IDSA low-moderate-quality evidence).
- American Academy of Pediatrics recommends the following (1)[C]:
  - Amoxicillin: 45 to 90 mg/kg/day in 2 divided doses if uncomplicated acute bacterial sinusitis in children
  - Amoxicillin-clavulanate: 80 to 90 mg/6.4 mg/kg/day in 2 divided doses for children with severe illness, recent antibiotics, or attending daycare
  - Levofloxacin: 10 to 20 mg/kg/day max 750mg/day if history of type 1 hypersensitivity to PCN (1)[C]
  - Clindamycin (30 to 40 mg/kg/day) + cefixime (8mg/kg/day in 2 divided doses) or cefpodoxime (10 mg/kg/day in 2 divided doses) (1)[C] for non-type 1 PCN allergy
  - Ceftriaxone: 50 mg/kg IM single dose if not able to tolerate oral meds (4)[C]
- Because allergies may be a predisposing factor, some patients may benefit from use of the following agents:
  - Oral antihistamines
    - Loratadine (Claritin), fexofenadine (Allegra), cetirizine (Zyrtec), desloratadine (Clarinex), or levocetirizine (Xyzal)
    - Chlorpheniramine (Chlor-Trimeton)
    - Diphenhydramine (Benadryl)
  - Leukotriene inhibitors (Singulair, Accolate), especially in patients with asthma
  - Nasal steroids (i.e., fluticasone [Flonase])

## *Second Line*

- Levofloxacin (Levaquin): 750 mg/day for 5 days or moxifloxacin 400 mg/day for 5 to 7 days (adults only) (1)[C]
- If no response to first-line therapy after 72 hours
  - Broaden antibiotic coverage or switch to a different class, evaluate for resistant pathogens or other causes for treatment failure (i.e., noninfectious etiology) fluoroquinolones as above.

- *Note:* Bacteriologic failure rates of up to 20-25% are possible with use of azithromycin and clarithromycin.
- If lack of response to 3 weeks of antibiotics, consider the following:
  - CT scan of sinuses
  - Ear/nose/throat (ENT) referral

## ***ISSUES FOR REFERRAL***

Complications or failure of treatment

### **ALERT**

- Meta-analyses have demonstrated no benefit of newer antibiotics over amoxicillin or doxycycline.
- Antibiotics recommendations vary with different guidelines. Patients seen by specialists are different from those in a primary care setting. Patients usually do not have complicated sinusitis in primary care setting.
  - American Academy of Otolaryngology—Head and Neck Surgery Foundation (2)[C] recommends the following:
    - Consider watchful waiting without antibiotics in patients with uncomplicated mild illness (mild pain and temperature <101°F) with assurance of follow-up within 7 days.
- PCV-13 pneumococcal vaccine can be helpful in reducing chronic sinusitis in children (5)[B].
- Use of intranasal steroids small but significant improvement in symptoms when used alone or in combination with antibiotics (6)[A].
- Precautions
  - Decongestants can exacerbate hypertension.
  - Intranasal decongestants should be limited to 3 days to avoid rebound nasal congestion.

## ***Pregnancy Considerations***

- Nasal irrigation with saline, pseudoephedrine, most antihistamines, and some nasal steroids are safe during pregnancy and lactation.
- Antibiotics safe in pregnancy and lactation
  - Amoxicillin, amoxicillin-clavulanate, cephalosporins

- Antibiotic contraindicated: doxycycline, fluoroquinolones
- Antibiotic safe in lactation but not pregnancy: levofloxacin

## ***SURGERY/OTHER PROCEDURES***

- If medical therapy fails, consider sinus irrigation.
- Functional endoscopic sinus surgery is the preferred treatment for medically recalcitrant cases.
- Absolute surgical indications
  - Massive nasal polyposis
  - Acute complications: subperiosteal or orbital abscess, frontal soft tissue spread of infection
  - Mucocele or mucopyocele
  - Invasive or allergic fungal sinusitis
  - Suspected obstructing tumor
  - CSF rhinorrhea

## ***INPATIENT CONSIDERATIONS***

Hospitalization for complications (e.g., meningitis, orbital cellulitis or abscess, brain abscess)

## **ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

Return if no improvement after 72 hours or no resolution of symptoms after 10 days of antibiotics.

## ***PATIENT EDUCATION***

- <http://familydoctor.org/familydoctor/en.html>
- <https://www.nlm.nih.gov/medlineplus/>

## ***PROGNOSIS***

Alleviation of symptoms within 72 hours with complete resolution within 10 to 14 days

## **COMPLICATIONS**

- Serious complications are rare.

Meningitis, orbital cellulitis, brain abscess

- Cavernous sinus thrombosis
- Osteomyelitis, subdural empyema

**&NA;**

## **ICD10**

- J01.90 Acute sinusitis, unspecified
- J01.00 Acute maxillary sinusitis, unspecified
- J01.20 Acute ethmoidal sinusitis, unspecified

## **Clinical Pearls**

**&NA;**

- When bacterial infection is present, patients recover somewhat more quickly with antibiotics, but the majority will recover with symptomatic treatment alone, and accurate diagnosis of bacterial sinusitis is very difficult.
- Multiple meta-analyses have demonstrated *no* benefit of newer antibiotics over amoxicillin or doxycycline.
- Overall NNT to prevent 1 persistent case at follow-up = 15; harm due to antibiotic-associated diarrhea is similar.
- Significant patient symptom relief with nasal saline spray or drops or irrigation (Neti pot)

# Sjögren Syndrome

Mariya Milko, DO, MS

Rubaiya Mallay, DO, FACOI, ACR

## BASICS

- Chronic inflammatory disorder characterized by lymphocytic infiltrates in exocrine organs
- Typically presents with diminished salivary and lacrimal gland function, resulting in sicca symptoms such as dry eyes (xerophthalmia), dry mouth (xerostomia), and parotid enlargement
- Extraglandular manifestations: arthralgia, myalgia, Raynaud phenomenon, pulmonary disease, GI disease, leukopenia, anemia, lymphadenopathy, vasculitis, renal tubular acidosis, lymphoma, CNS involvement with longitudinal transverse myelitis (>4 vertebral segments), and optic neuritis associated with anti-aquaporin-4 antibodies, PNS involvement with small fiber neuropathy
- Primary Sjögren: Not associated with other diseases; *HLA-DRB1\*0301* and *HLA-DRB1\*1501* are the most common.
- Secondary Sjögren: complication of other rheumatologic conditions, most commonly rheumatoid arthritis; associated with HLA-DR4
- First described by Swedish ophthalmologist Henrik Sjögren (1899-1986)

## EPIDEMIOLOGY

### Incidence

Annual incidence:  $\div 4/100,000$ . Primary SS is one of the most common autoimmune diseases, affecting 1-4% of population.

- All races are affected
- Predominant sex: female > male (9:1)
- Predominant age: can affect patients of any age but is most common in the elderly; onset typically in the 4th to 5th decades of life

### Prevalence

Sjögren syndrome (SS) affects 1 to 4 million people in the United States.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Multifactorial systemic autoimmune process characterized by infiltration of glandular tissue by CD4 T-lymphocytes
- Theorized that glandular epithelial cells present antigen to the T cells. Cytokine production then occurs. There is also evidence for B-cell activation, resulting in autoantibody production and an increased incidence of B-cell malignancies.
- Etiology is unknown. Estrogen may play a role because SS is more common in women. Exogenous factors such as viral proteins (EBV, HCV, HTLV-1) have also been implicated.

### Genetics

- A familial tendency suggests a genetic predisposition.
- Associations in the HLA regions *HLA-DQA1\*0501*, *HLA-DQB1\*0201*, and *HLA-DRB\*0301* are the strongest genetic risk factors for SS.

## RISK FACTORS

There are no known modifiable risk factors.

## GENERAL PREVENTION

- No known prevention. Complications can be prevented by early diagnosis and treatment.
- Oral health providers play a key role in early detection and management of symptoms resulting from salivary dysfunction (1)[C].

## COMMONLY ASSOCIATED CONDITIONS

Secondary SS associated with rheumatoid arthritis, scleroderma, systemic lupus erythematosus (SLE), polymyositis, HIV, hepatitis C, MCTD, PBC, hypergammaglobulinemic purpura, necrotizing vasculitis, autoimmune thyroiditis, chronic active hepatitis, mixed cryoglobulinemia

### Pregnancy Considerations

Pregnant SS patients with anti-SSA Abs have increased risk of delivering fetus with skin rash and 3rd-degree heart block.

## DIAGNOSIS

- American College of Rheumatology Diagnostic Criteria (2)[A]: Individuals with signs/symptoms that may be suggestive of SS, who have at least two of the following three objective features:

- Positive serum anti-SSA/Ro and/or anti-SSB/La or (positive rheumatoid factor and ANA titer  $\geq 1:320$ )
- Labial salivary gland biopsy exhibiting focal lymphocytic sialadenitis with a focus score  $\geq 1$  focus/4 mm<sup>2</sup>
- Keratoconjunctivitis sicca with ocular staining score  $>3$  (assuming that individual is not currently using daily eye drops for glaucoma and has not had corneal surgery or cosmetic eyelid surgery in the last 5 years)
- Ocular signs and symptoms
  - Troublesome dry eyes daily for  $>3$  months
  - Recurrent sandy/gritty ocular sensation
  - Use of tear substitute  $>3$  times per day
- Oral signs and symptoms
  - Daily symptoms of dry mouth for  $\geq 3$  months
  - Recurrent feeling of swollen salivary glands
  - Need to drink liquid to help swallow dry foods
- Other manifestations: chronic arthritis, type 1 RTA, tubular interstitial nephritis, rheumatoid arthritis, vasculitis, vaginal dryness, pleuritis, pancreatitis

## HISTORY

- Decreased tear production; burning, scratchy sensation in eyes
- Difficulty speaking/swallowing, dental caries, xerotrachea
- Enlarged parotid glands or intermittent swelling (bilateral)
- Dyspareunia; vaginal dryness

## PHYSICAL EXAM

Common physical exam findings include:

- Eye exam: dry eyes (keratoconjunctivitis sicca), decreased tear pool in the lower conjunctiva, dilated conjunctival vessels, mucinous threads, and filamentary keratosis (slit-lamp examination)
- Mouth exam: dry mouth (xerostomia); decreased sublingual salivary pool (tongue may stick to the tongue depressor); frequent oral caries (sometimes in unusual locations such as the incisor surface and along the gum line); dark red tongue from prolonged xerostomia

- Ear, nose, and throat exam: parotid enlargement, submandibular enlargement
- Skin exam: nonpalpable or palpable vasculitic purpura (typically 2 to 3 mm in diameter and on the lower extremities)

## ***DIFFERENTIAL DIAGNOSIS***

- Causes of ocular dryness: hypovitaminosis A, decreased tear production unrelated to autoimmune process, chronic blepharitis or conjunctivitis, impaired blinking (i.e., due to Parkinson disease or Bell palsy), infiltration of lacrimal glands (i.e., amyloidosis, lymphoma, sarcoidosis), low estrogen levels
- Causes of oral dryness: anticholinergic medications, sialadenitis due to chronic obstruction, chronic viral infections (i.e., hepatitis C or HIV), radiation of head/neck
- Causes of salivary gland swelling: unilateral: obstruction, chronic sialadenitis, bacterial infection, neoplasm; bilateral (asymmetric): IgG4-related disease, HIV bilateral (symmetric): hepatic cirrhosis, DM, anorexia/bulimia, acromegaly, alcoholism, hypolipoproteinemia, chronic pancreatitis, acute or chronic viral infection (i.e., mumps, Epstein-Barr virus [EBV], coxsackievirus, echovirus, granulomatous diseases (i.e., tuberculosis, sarcoidosis)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

The following tests can be used to support diagnosis:

- Schirmer test (<5-mm wetness after 5 minutes)
- Rose Bengal test (slit lamp)
- Minor salivary gland biopsy (gold standard)
- Auto antibodies: +ANAs (95%), +RF (75%)
- In primary SS: +anti-Ro (anti-SSA, 56%) and +anti-La (anti-SSB, 30%)

### ***Initial Tests (lab, imaging)***

Preliminary lab workup

- Basic labs: CBC with differential, BUN/creatinine (Cr), AST/ALT, ESR, C-reactive protein (CRP), urinalysis (UA)
- Special labs: ANA, rheumatoid factor (RF), anti-Ro/SSA, anti-La/SSB, ESR, CRP
- Anti-SSA and anti-SSB antibodies present in 33-74% and 23-52% of SS patients, respectively.
- Other auto antibodies-muscarinic receptor type 3 (M3R) and anti-*agr*-fodrin are being explored with good specificity (3)[A].

- Initial imaging studies may include:
  - Imaging for xerostomia: salivary gland scintigraphy (insensitive but highly specific)
  - Parotid gland sialography (should not be used in acute parotitis)
  - MRI (correlates well with salivary gland biopsy)
- A novel diagnostic tool is Salivary Gland US (SGUS) which is noninvasive and highly specific for salivary gland involvement in SS (4)[A].

P.971

## *Diagnostic Procedures/Surgery*

- Salivary gland biopsy: used to confirm suspected diagnosis of SS or to exclude other causes of xerostomia and bilateral glandular enlargement
- Parotid biopsy if malignancy is suspected
- Lymph node biopsy to rule out pseudolymphoma or lymphoma if suspected

## *Test Interpretation*

- Salivary gland histology shows focal collections of lymphocytes; immunocytology shows CD4+ T cell lymphocyte predominance.
- SGUS parameters include:
  - Parenchymal nonhomogeneity—the most useful diagnostic marker with high specificity and good sensitivity (4)[A].
  - US inflammatory findings include hypoechoic and hyperechoic bands (4)[A].
  - Real-time sonoelastography (RTS) to quantify tissue rigidity and assess glandular damage (4)[A]

## **TREATMENT**

- Treatment is primarily supportive.
- Treat sicca symptoms—dry eyes, dry mouth
- Avoid medications that may worsen oral dryness (i.e., anticholinergics).
- Promote good oral hygiene.
- Treat systemic manifestations.
- Address fatigue and pain.

## *MEDICATION*

- Therapy for sicca symptoms: artificial tears and ocular lubricants (5)[C]
- Topical therapy for dry mouth: can be as simple as liberally drinking sips of water, trying sugar-free lemon drops or artificial saliva preparations such as Salivart, Saliment, Xero-Lube, MouthKote
- Immunosuppressive therapy such as hydroxychloroquine can be used for systemic symptoms; however, it has not shown any benefit in relieving refractory sicca symptoms.
- Evoxac (Cevimeline) may be prescribed for SS-associated xerostomia. It works by stimulating muscarinic cholinergic receptors to increase salivary gland secretion.
- Dry eyes are graded by severity of symptoms, conjunctival injection and staining, corneal damage, tear quality, and lid involvement. Artificial tears may be used; however, artificial tears with hydroxyethylcellulose or dextran are more viscous and can last longer.
- Acetaminophen or NSAIDs for arthralgias

### *First Line*

- Xerostomia: sugar-free lozenges, especially malic acid, artificial saliva; pilocarpine 5 mg PO QID or cevimeline 30 mg PO TID
- Keratoconjunctivitis sicca: artificial tears and ocular lubricants for symptomatic relief, topical cyclosporine (Restasis), or autologous tears

### *Second Line*

- Xerostomia: Interferon-alfa lozenges may enhance salivary gland flow.
- Keratoconjunctivitis sicca: topical glucocorticoids or topical NSAIDs (use with caution)
- Immunosuppressive therapy: antimalarials (e.g., hydroxychloroquine) for arthralgias, lymphadenopathies, and skin manifestations; may then consider methotrexate or cyclosporine, which showed subjective improvement but no significant objective improvement
- Early studies show improvement in fatigue with rituximab (6)[B].
- For life-threatening extraglandular manifestations, cyclophosphamide (PO or IV), mycophenolate mofetil, and azathioprine are often used.

## *ISSUES FOR REFERRAL*

- A rheumatologist can help with management of systemic manifestations or resistant symptoms.

- Oral health
- Ophthalmology, for grading of severity and management of xerophthalmia

## ***ADDITIONAL THERAPIES***

- Patients should use vaginal lubricants, such as Replens, for vaginal dryness. Vaginal estrogen creams can help in postmenopausal women. Be alert for and treat vaginal yeast infections.
- Xerostomia: small sips of water, good dental care
- Keratoconjunctivitis sicca: Conserve tears with side shields or ski/swim goggles, humidifiers, and moist washcloths.
- Dehydroepiandrosterone (DHEA) does not offer improvement in fatigue and well-being above placebo.

## ***SURGERY/OTHER PROCEDURES***

Keratoconjunctivitis sicca: If refractory to artificial tears, punctal occlusion is the treatment of choice.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Some studies show acupuncture benefits saliva production and symptoms of xerostomia.
- There is insufficient evidence to determine the effects of electrostimulation devices on dry mouth symptoms or saliva production in patients with Sjögren syndrome.

## ***INPATIENT CONSIDERATIONS***

May be required for extraglandular manifestations, such as cardiopulmonary disease, renal involvement, and CNS manifestations (e.g., optic neuritis, transverse myelitis, vasculitis, or ischemic stroke)

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Frequency of follow-up depends on severity

#### ***Patient Monitoring***

- Monitor for complications, systemic manifestations, and relief of symptoms.
- Medicolegal pitfalls: Monitor for parotid tumor or lymphoma.

## PATIENT EDUCATION

In most cases, simple measures are adequate: humidifiers, sips of water, chewing gum, or artificial tears.

## PROGNOSIS

- Hypocomplementemia is an independent risk factor for premature death.
- Primary SS is associated with increased risks of malignancy, non-Hodgkin lymphoma, and thyroid cancer.

## COMPLICATIONS

Complications include dental caries, gum disease, dysphagia, salivary gland calculi, keratitis, conjunctivitis, and scarring of the ocular surface.

---

# Codes

**&NA;**

## ICD10

- M35.00 Sicca syndrome, unspecified
- M35.02 Sicca syndrome with lung involvement
- M35.09 Sicca syndrome with other organ involvement

## Clinical Pearls

**&NA;**

- Many symptoms of SS can be treated with simple interventions such as artificial tears and sugar-free lozenges.
- Consider lacrimal duct plugs for dry eyes.
- Consider SS in patients with unexplained lung disease and +ANA.
- Patients with primary SS may have an increased incidence of celiac disease because both disease share similar genetics.

# Sleep Apnea, Obstructive

Sonya Shipley, MD

## BASICS

### DESCRIPTION

- Obstructive sleep apnea (OSA) is defined as repetitive episodes of cessation of airflow (apnea) at the nose and mouth during sleep due to obstruction at the level of the pharynx.
  - Apneas often terminate with a snort/gasp.
  - Repetitive apneas produce sleep disruption, leading to excessive daytime sleepiness.
  - Associated with oxygen desaturation and nocturnal hypoxemia
  - Usual course is chronic.
- System(s) affected: cardiovascular; nervous; pulmonary
- Synonym(s): Pickwickian syndrome; sleep apnea syndrome; nocturnal upper airway occlusion

### EPIDEMIOLOGY

#### *Incidence*

- Predominant age: middle-aged men and women
- Predominant sex: male > female (2:1)

#### *Prevalence*

- Up to 4% in men, 2% in women
- Prevalence is higher in obese/hypertensive patients.

### ETIOLOGY AND PATHOPHYSIOLOGY

OSA occurs when the naso- or oropharynx collapses passively during inspiration. Anatomic and neuromuscular factors contribute to pharyngeal collapse.

- Anatomic abnormalities such as increased soft tissue in the palate, tonsillar hypertrophy, macroglossia, and craniofacial abnormalities, predispose the airway to collapse by decreasing

the area of the upper airway or increasing the pressure surrounding the airway.

- During sleep, decreased muscle tone in the naso- or oropharynx contributes to airway obstruction and collapse.
- Upper airway narrowing may be due to the following:
  - Obesity, redundant tissue in the soft palate
  - Enlarged tonsils/uvula
  - Low soft palate
  - Large/posteriorly located tongue
  - Craniofacial abnormalities
  - Neuromuscular disorders
  - Alcohol/sedative use before bedtime

## *RISK FACTORS*

- Obesity
- Age >40 years
- Alcohol/sedative intake before bedtime
- Smoking
- Nasal obstruction (due to polyps, rhinitis, or deviated septum)
- Anatomic narrowing of nasopharynx (e.g., tonsillar hypertrophy, macroglossia, micrognathia, retrognathia, craniofacial abnormalities)
- Acromegaly
- Hypothyroidism
- Neurologic syndromes (e.g., muscular dystrophy, cerebral palsy)

## *GENERAL PREVENTION*

Weight control and avoidance of alcohol and sedatives at night can help to prevent airway collapse.

## *COMMONLY ASSOCIATED CONDITIONS*

- Common
  - Hypertension

- Obesity
- Daytime sleepiness
- Metabolic syndrome
- Rare
  - Cardiac arrhythmias
  - Cardiovascular disease
  - Congestive heart failure
  - Pulmonary hypertension
  - Nasal obstructive problems

## DIAGNOSIS

### HISTORY

- Elicit a complete history of daytime and nighttime symptoms. Symptoms can be insidious and present for years.
- Daytime symptoms
  - Excessive daytime sleepiness (EDS) or fatigue (cardinal symptom) (1)[A]
    - Mild symptoms occur during quiet activities (e.g., reading, watching television).
    - Severe symptoms occur during dynamic activities (e.g., work, driving).
  - Tired on morning awakening
  - Sore/dry throat
  - Poor concentration, memory problems, irritability, mood changes
  - Morning headaches
  - Decreased libido
  - Depression
- Nighttime symptoms
  - Loud snoring (present in 60% of people with OSA)
  - Snort/gasp that arouses patient from sleep
  - Disrupted sleep
  - Witnessed apneic episodes at night

## *PHYSICAL EXAM*

- OSA is commonly associated with obesity. It is unlikely to be found in those with normal body weight who do not snore (1)[A].
- Focused head and neck exam
  - Short neck with large circumference
  - Oropharynx
    - Narrowing of the lateral airway wall
    - Tonsillar hypertrophy
    - Macroglossia
    - Micrognathia/retrognathia
    - Soft palate edema
    - Long/thick uvula
    - High, arched hard palate
  - Nasopharynx
    - Deviated nasal septum
    - Poor nasal airflow

## *DIFFERENTIAL DIAGNOSIS*

- Other causes of EDS such as the following:
  - Narcolepsy
  - Idiopathic daytime hypersomnolence
  - Inadequate sleep time
  - Depressive episodes with EDS
  - Periodic limb movements disorder
- Respiratory disorders with nocturnal awakenings such as the following:
  - Asthma
  - Chronic obstructive pulmonary disease
  - Congestive heart failure

- Central sleep apnea
- Sleep-related choking/laryngospasm
- Gastroesophageal reflux
- Sleep-associated seizures (temporal lobe epilepsy)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- When clinically indicated
  - Thyroid-stimulating hormone to evaluate hypothyroidism
  - CBC to evaluate anemia and polycythemia, which can indicate nocturnal hypoxemia.
  - Fasting glucose in obesity to evaluate for diabetes
  - Rare: arterial blood gases to evaluate daytime hypercapnia
- Cephalometric measurements from lateral head and neck radiographs aid in surgical treatment.

### *Diagnostic Procedures/Other*

- The gold standard for OSA is polysomnography (PSG), a nighttime sleep study (1)[A].
  - Demonstrates severity of hypoxemia, sleep disruption, and cardiac arrhythmias associated with OSA and elevated end-tidal CO<sub>2</sub>
  - Shows repetitive episodes of cessation/marked reduction in airflow despite continued respiratory efforts
  - Apneic episodes must last at least 10 seconds and occur 10 to 15 times per hour to be considered clinically significant.
  - Complete PSG is expensive, and health insurance may not cover the cost.
- Multiple sleep latency testing is a diagnostic tool used to measure the time it takes from the start of a daytime nap period to the first signs of sleep (sleep latency). It provides an objective measurement of daytime sleepiness.
- The apnea-hypopnea index (AHI) is defined as the total number of apneas and hypoapneas divided by the total sleep time.
  - Mild OSA: AHI = 5 to 15
  - Moderate OSA: AHI = 15 to 30

- Severe OSA: AHI >30
- Drugs that may alter the test results include benzodiazepines and other sedatives that can amplify the severity of apnea seen during the sleep study.
- Early data suggest that home-based diagnosis using portable monitoring devices may be an alternative to laboratory-based PSG if the test is of sufficient duration (2)[B].

## TREATMENT

- Lifestyle modification is the most frequently recommended treatment for mild to moderate OSA. This includes weight loss, exercise, and avoidance of alcohol, smoking, and sedatives, especially before bedtime. Weight loss has been shown to decrease the severity of symptoms in obese patients. Lifestyle modifications should be seen as adjunctive rather than curative therapy (3)[A], and a lack of improvement of symptoms with lifestyle modification should not preclude patients from receiving other therapy such as continuous positive airway pressure (CPAP).
  - If OSA is present only when supine, keep the patient off his/her back when sleeping (e.g., tennis ball worn on back of nightshirt or using a sleep position trainer) (4)[B].
- 
- P.973
- The most effective therapy for mild, moderate, or severe OSA is CPAP (5)[B]. Treatment with CPAP uses a mask interface and a flow generator to prevent airway collapse, thus helping to prevent apnea, hypoxia, and sleep disturbance. Compared with inactive controls, CPAP significantly improves both objective (24-hour systolic and diastolic blood pressures) and subjective measures (Epworth Sleepiness Scale) in OSA patients with symptoms of daytime sleepiness (6)[A]. CPAP may also decrease the risk for atherosclerosis (7)[A] as well as improves insulin resistance in nondiabetic patients (8)[A]. Early data show that these benefits may not be seen in patients who do not have symptoms of daytime sleepiness (9)[B].
  - Several types of mask interfaces, including nasal masks, oral masks, and nasal pillows exist for CPAP therapy. Short-term data suggest that nasal pillows are the preferred interface in almost all patients. In patients with compliance difficulty, a different choice of interface may be appropriate (10)[A].
  - Oral appliances to treat OSA are available and often subjectively preferred by patients. Although oral appliances have been shown to improve symptoms compared with inactive controls, they are not as effective for reduction of respiratory disturbances as CPAP over short-term data. Treatment with oral appliances may be considered in patients who fail to comply with CPAP therapy (11)[A].

## **MEDICATION**

Medications are yet to be proven effective in treating OSA (12)[A]. Further studies in this area are needed.

### ***First Line***

Some short-term data found fluticasone nasal spray, mirtazapine, physostigmine, and nasal lubricant of some benefit; longer-term studies needed.

## **ISSUES FOR REFERRAL**

If sleep apnea is suspected, patient should be referred to a sleep specialist/neurologist for a sleep study evaluation.

## **SURGERY/OTHER PROCEDURES**

Surgical corrections of the upper airway include alteration of the uvula and/or palate such as uvulopalatopharyngoplasty (UPPP), tracheostomy, and craniofacial surgery. Currently no evidence supports the use of surgery for the treatment of OSA (13)[A].

## **INPATIENT CONSIDERATIONS**

On admission, patients should continue to use CPAP/dental devices if they do so at home. They should bring in their own appliance and know their CPAP settings.

## **ONGOING CARE**

Lifelong compliance with weight loss or CPAP is necessary for successful OSA treatment.

## **DIET**

Overweight and obese patients should be encouraged to lose weight, and all patients must avoid weight gain. Weight loss alone could reduce symptoms of OSA (14)[A].

## **PATIENT EDUCATION**

- Weight loss and avoidance of alcohol and sedatives may reduce OSA symptoms particularly in severe cases (15)[A].
- Significantly sleepy patients should not drive a motor vehicle/operate dangerous equipment.

## **PROGNOSIS**

- EDS is reduced dramatically with appropriate apnea control.

Lifelong compliance with weight loss or CPAP is necessary for effective treatment of OSA.

- If untreated, OSA is progressive.
- Significant morbidity and mortality with OSA usually are due to motor vehicle accidents or are secondary to cardiac complications, including arrhythmias, cardiac ischemia, and hypertension.

## **COMPLICATIONS**

Untreated OSA may increase the risk for development of hypertension, stroke, myocardial infarction, diabetes, cardiovascular disease, and work-related and driving accidents.

### ***Pediatric Considerations***

- The prevalence of pediatric OSA is 1-2% in children 4 to 5 years of age, and the peak incidence is between 3 and 6 years of age.
- Predominant sex: male = female
- Etiology: The most common cause is tonsillar hypertrophy. Additional causes are obesity and craniofacial abnormalities. OSA is also seen in children with neuromuscular diseases, such as cerebral palsy and spinal muscular atrophy, due to abnormal pharyngeal muscle control.
- Signs and symptoms
  - Nighttime: loud snoring, restlessness, and sweating
  - Daytime: hyperactivity and decreased school performance
  - EDS is not a significant symptom.
- Diagnosis: Gold standard is PSG (PSG may be an even better tool in children due to lessened night-to-night variation. There is a lack of studies showing efficacy of home-based diagnostic studies vs. PSG in children). Abnormal AHI is different in children: >1 to 2/hr is abnormal.
- Treatment: Surgery is the first-line treatment in cases due to tonsillar enlargement (reduces symptoms in 70%). Some data suggest improved academic performance if tonsillectomy is performed for OSA. For cases due to obesity/craniofacial abnormalities, patients can use CPAP treatment (16)[A].

### ***Geriatric Considerations***

The presence of sleep apnea in the geriatric population may be associated with earlier onset of mild cognitive impairment as well as Dementia at an earlier age. The rate of decline of cognitive function may be slowed by the usage of CPAP (17)[B].

## Codes

**&NA;**

### ICD10

G47.33 Obstructive sleep apnea (adult) (pediatric)

## Clinical Pearls

**&NA;**

- OSA is characterized by repetitive episodes of apnea at the pharynx, often terminating in a snort/gasp.
- Laboratory PSG is the key to diagnosis.
- CPAP is the most effective form of treatment for both mild to moderate and moderate to

severe OSA.

- Central sleep apnea may mimic OSA.

# Sleep Disorder, Shift Work

Ronald G. Chambers Jr., MD, FAAFP

Cindy J. Chambers, MD, MAS, MPH

## BASICS

### DESCRIPTION

- The human system fundamentally relies on a natural circadian rhythm coordinated by the suprachiasmatic nucleus (SCN), an endogenous clock or pacemaker of the hypothalamus, which is responsible for linking the nervous system to the endocrine system (1).
- A shift in work schedule can desynchronize this circadian pacemaker with peripheral cells.
- The major environmental factor that can disrupt or reset the circadian rhythm is light at night (LAN) (1).
- Shift work disorder (SWD), also classified as circadian rhythm sleep disorder, shift work is a sleep disorder caused by a misalignment between the internal circadian rhythm and the required sleepwake schedule resulting from erratic or nighttime shift work (2).
- Diagnostic criteria for SWD requires that all criteria for circadian rhythm disorders be met in addition to specific SWD criteria (see below).
- Criteria for circadian rhythm disorder:
  - A persistent/recurrent sleep disruption due to either an alteration in the circadian (24-hour) timekeeping system or due to a misalignment between endogenous circadian rhythm and exogenous factors that affect sleep
  - A complaint of insomnia/excessive daytime sleepiness or both
  - An impairment in occupational, educational, or social functioning
  - Insomnia or excessive sleepiness temporarily associated with a recurring work schedule that overlaps with the usual time for sleep
  - Symptoms associated with shift work schedule are present for at least 1 month
  - Sleep log or actigraphy monitoring (with sleep diaries) for at least 7 days demonstrates disturbed sleep (insomnia) and circadian and sleep time misalignment
  - Sleep disturbance is not due to another current sleep disorder, substance use disorder, or

medication use.

## EPIDEMIOLOGY

### Prevalence

- Shift workers include those who work night shifts, evening shifts, or rotating shifts, and comprise approximately 15-25% of the workforce in the United States (2).
- SWD has been estimated to affect 10-23% of the presently 22 million American shift workers, with a prevalence estimate of approximately 2-5% of the general population (14.1% night shift workers and 8.1% of rotating shift workers) (3).

## PATHOPHYSIOLOGY

- Circadian rhythms are evident in multiple biologic functions, including body temperature, hormone levels, blood pressure, metabolism, cellular regeneration, sleep/wake cycles, and DNA transcription and translation (2).
- Transcription factors involved in circadian rhythm generation collectively referred to as the "molecular clock," control production of the many proteins that are expressed within a period of approximately 24 hours. This molecular clock is self-sustaining but requires resetting daily or it may become out of sync with environmental cues also called "zeitgebers" (2).
- The most powerful *zeitgeber*, or timekeeper, is light. Light transmitted from the retinohypothalamic tract of the eye to the SCN of the hypothalamus upregulates the production of the "clock gene" (PER) (2).
- Periods of darkness cause the SCN to induce the release of melatonin from the pineal gland, which can also help to reset the molecular clock (2).
- A dysynchrony between the endogenous molecular clock and external cues (most notably light/dark cycles) is responsible for the development of circadian rhythm disorders and can have a severe impact on both physical and mental health (2).

## RISK FACTORS

- Shift work, including night shifts, early morning shifts, or rotating shifts
- Younger age and "eveningness" (a.k.a. "night owls" rather than "morning larks") may provide some protection from the development of SWD (2).

### Genetics

No genetic predisposition has been described.

## GENERAL PREVENTION

- Limit rotating shifts.
- Use of bright light during shifts
- Scheduling brief, strategic 10- to 20-minute naps during shifts, if suitable

## COMMONLY ASSOCIATED CONDITIONS

- Shift workers in general have impaired immediate free recall, decreased processing speed, and selective attention, impairments that may worsen with longer duration of shift work (2).
- Shift workers also have been shown to have a much higher risk of vehicular accidents, job-related injuries, absenteeism, and quality control errors (2).
- SWD has been associated with GI disease, specifically peptic ulcer disease, cardiovascular disease (CVD), infertility, mood disorders, and pregnancy complications (2).
- There is also evidence for possible increased risk of breast and prostate cancer. As such, the International Agency for Research on Cancer (IARC) has classified shift work that involves a circadian disruption as a probable carcinogen (1).

## DIAGNOSIS

This is primarily a clinical diagnosis. However, there are some useful diagnostic aids.

### HISTORY

- A careful history is critical to assess sleep disturbance including difficulty falling asleep, staying asleep, or nonrestorative sleep.
- Special attention should be paid to the following (4)[C]:
  - Sleep/wake habits
  - Degree of alertness or sleepiness
  - Sleep environment
  - Light exposure before, during, and after the shift
  - Job-related factors: length of shift, number of consecutive shifts, commute after shift.
  - Medications as well as over-the-counter (OTC) stimulants such as caffeine and energy drinks
  - Impact on social and domestic responsibilities (including drowsy driving)
- It is also essential to evaluate for symptoms of other sleep disorders, which often coexist and can exacerbate SWD such as the following:

- Snoring (obstructive sleep apnea [OSA])
- Sudden sleep attacks and leg symptoms (restless legs syndrome [RLS])
- Falling asleep at inappropriate times, drop attacks, and daytime fatigue (narcolepsy)

## *PHYSICAL EXAM*

Evaluate for depression, GI, CV, and potential cancer risk as well as signs of OSA such as obesity, a large neck, and a tight oropharynx (4)[C].

## *DIFFERENTIAL DIAGNOSIS*

- Other primary sleep disorders: OSA, RLS, narcolepsy, and psychophysiologic insomnia.
- Other circadian rhythm sleep disorder such as delayed sleep phase disorder or jet lag syndrome. Distinguishing among these is challenging even for sleep specialists.

## *DIAGNOSTIC TESTS & INTERPRETATION*

Given possible increased risk for CVD and cancer among shift workers, consider appropriate screenings.

### *Initial Tests (lab, imaging)*

Fasting lipid panel, fasting glucose, age-appropriate cancer screenings

### *Diagnostic Procedures/Other*

- Evaluation of a sleep/wake diary that records the patient's sleep/wake habits including amount of sleep, naps during the waking hours, and mood (1 to 2 weeks) (4)[C].
- Consider actigraphy (a mechanical device, often worn on the arm/leg, to measure movement): serves as a gross measure of time and amount of activity and rest (4)[C]
- Polysomnography, a measure of sleep duration and quality is not typically used to diagnose SWD but may be helpful in ruling out other sleep/wake disorders such as sleep apnea and narcolepsy (2)[C].
- Several diagnostic tools are available including the Multiple Sleep Latency Test (MSLT), the Morningness-Eveningness Questionnaire (MEQ), and the Epworth Sleepiness Scale (ESS) to help determine circadian misalignment (2)[C].

### *Test Interpretation*

Typically, sleep diaries and actigraph data reveal the following:

- Increased sleep latency
- Decreased total sleep time
- Frequent awakenings
- Notably, most people revert to nocturnal sleeping on their days off, meaning that every workweek, they start fresh in their attempt to shift their circadian rhythms to align with work schedules.

## TREATMENT

- The only therapeutic modality deemed as 'standard' by the American Academy of Sleep Medicine is planned (or prescribed) sleep schedules (5)[C].
- Other commonly used treatment strategies include optimizing sleep hygiene, bright light, melatonin, caffeine and other stimulants as well as hypnotics and other medication sleep aids (discussed below).

## GENERAL MEASURES

- Sleep hygiene: An important first step in approaching the treatment of sleep disorders is to educate the patient on proper sleep hygiene including minimizing exposure to bright light before and during scheduled sleep periods (maintain a dark sleeping space, wear dark sunglasses following work shift, wearing eye mask to sleep), maintaining a quiet sleep environment (wearing ear plugs to sleep, disconnecting phone, doorbell), retraining core body temperature to shifted sleep/wake schedule (maintain cool sleeping quarters), and avoiding use of stimulants during second half of work shift (2)[C].
- Sleep time: Educate on need of protected time for sleep prior to and following work shifts with strategic use of naps when possible (4)[C].
- Address work/social/domestic factors: Treat psychosocial stress, depression, encourage healthy eating habits, limit substance use, increase exercise to at least 30 minutes 5 times per week (not within 2 to 4 hours of bedtime) (4)[C].
- Work-related interventions: If possible, reduce number of consecutive shifts (<4) or reduce shift duration (<12 hours), allow adequate time between shifts (>11 hours), and move heavy workload outside circadian nadir (04:00 to 07:00) (4)[C].
- Bright light: Several studies have demonstrated that timed bright light and darkness can promote adaptation to night work (6)[C].
- Bright light therapy with conventional light/light boxes (10,000 lux preferable, but >1,000 lux

will help) should be given 30 min/day during the night/early morning shift prior to the nadir of the core body temperature rhythm (6)[C].

## **MEDICATION**

- Melatonin may help shift circadian rhythms and can increase the quality and duration of sleep as well as increase alertness during the work shift.
- Ramelteon (Rozerem), a melatonin receptor agonist, is not FDA-approved for the treatment of SWD but may be helpful in improving daytime sleep (2)[C].
- Antidepressants: Doxepin (tricyclic) and trazodone are FDA-approved for the treatment of insomnia. Given at low doses, doxepin and trazodone can improve sleep without residual daytime impairment (2)[C].
- Intermediate-acting hypnotics zolpidem (Ambien) or eszopiclone (Lunesta) may be used (see below) but can cause postsleep sedation (2)[C].
- Wakefulness-promoting medications are as follows:
  - Modafinil and armodafinil are FDA approved for excessive sleepiness in patients with SWD and can reduce daytime sleepiness and improve cognitive performance (2)[C].
  - Prophylactic caffeine use (200 mg) immediately prior to work shift and during work shift (4) [C].

### **First Line**

Circadian shift/sleep promoting: Melatonin, 3 mg PO or sublingual, 30 minutes before daytime sleep period. It should be taken only when the patient is home and able to go to bed if the hypnotic effects begin (2)[C].

### **Second Line**

- Wakefulness-promoting:
  - Modafinil (Provigil) 100 to 200 mg PO 60 minutes before the shift begins
  - Armodafinil (Nuvigil) 150 to 250 mg is longacting (12 to 16 hours, depending on food intake) and should be used judiciously in SWD as not to impede a patient's ability to sleep after the shift.
- Sleep promoting:
  - Nonbenzodiazepine hypnotics
    - Zolpidem (Ambien) 5 to 10 mg or eszopiclone (Lunesta) 2 to 3 mg 30 minutes before

desired sleep period. Eszopiclone is the only hypnotic approved for use over 35 days.

- Antidepressants: Doxepin (1 to 6 mg) and trazodone (25 to 50 mg), 1 to 2 hours prior to bed (2)[C]
- Benzodiazepines: Estazolam, flurazepam, quazepam, temazepam, and triazolam are FDA-approved for the treatment of insomnia; however, they have high risk of tolerance and withdrawal, and should be used cautiously for short-term treatment of insomnia (2)[C].
- In general, hypnotics may improve daytime sleep; however, they do not appear to improve sleep maintenance, nighttime alertness, and may cause residual sedation during the work hours, potentially worsening SWD symptoms (2)[C].

## ISSUES FOR REFERRAL

Refer to a sleep specialist if there is suspicion of other primary sleep disorders; dependence on hypnotics, alcohol, or stimulants

## ONGOING CARE

## PATIENT EDUCATION

- Health care providers should discuss good sleep hygiene and recommend on how to optimize the sleep environment.
- Shift workers who need to sleep in the daytime must take serious measures to ensure that their sleep environment is cool, dark, and quiet.
- Reserve bedroom for sleeping and intimacy only. Remove all televisions and telephones from bedroom.
- When going to sleep, turn clock away from bed; discourage prolonged reading in bed.
- Blackout shades are usually necessary in order to achieve the proper darkness.

## Codes

&NA;

### ICD10

G47.26 Circadian rhythm sleep disorder, shift work type

## Clinical Pearls

&NA;

- SWD is associated with shortened and disturbed sleep, fatigue, decreased alertness, cognitive

decrements, increased injuries and accidents, reproductive problems, and risks to cardiovascular and gastrointestinal health, and has been classified as a carcinogen given possible association with breast and prostate cancer.

- The most important first diagnostic step in SWD is to obtain and evaluate a sleep diary.

# Smell and Taste Disorders

Beth Mazyck, MD

Daniel B. Kurtz, PhD

## BASICS

### DESCRIPTION

- The senses of smell and taste allow a full appreciation of the flavor and palatability of foods and also serve as a warning system against toxins, polluted air, smoke, and spoiled food.
- Physiologically, the chemical senses aid in normal digestion by triggering GI secretions. Smell/taste dysfunction may have a significant impact on quality of life.
- Loss of smell occurs more frequently than loss of taste, and patients frequently confuse the concepts of flavor loss (as a result of smell impairment) with taste loss (an impaired ability to sense sweet, sour, salty, or bitter).
- Smell depends on the functioning of CN I (olfactory nerve) and CN V (trigeminal nerve).
- Taste depends on the functioning of CNs VII, IX, and X. Because of these multiple pathways, total loss of taste (ageusia) is rare.
- Systems affected: nervous, upper respiratory

### EPIDEMIOLOGY

#### *Incidence*

There are ÷200,000 patient visits a year for smell and taste disturbances.

#### *Prevalence*

- Predominant sex: male > female. Men begin to lose their ability to smell earlier in life than women.
- Predominant age: Chemosensory loss is age dependent:
  - Age >80 years: 80% have major olfactory impairment; nearly 50% are anosmic.
  - Ages 65 to 80 years: 60% have major olfactory impairment; nearly 25% are anosmic.
  - Age <65 years: 1-2% have smell impairment.

- Estimated >2 million affected in the United States

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Smell and/or taste disturbances:
  - Nutritional factors (e.g., malnutrition, vitamin deficiencies, liver disease, pernicious anemia)
  - Endocrine disorders (e.g., thyroid disease, diabetes mellitus, renal disease)
  - Head trauma
  - Migraine headache (e.g., gustatory aura, olfactory aura)
  - Sjögren syndrome
  - Toxic chemical exposure
  - Industrial agent exposure
  - Aging
  - Medications (see below)
  - Neurodegenerative diseases (e.g., multiple sclerosis, Alzheimer disease, cerebrovascular accident, Parkinson disease)
  - Infections (e.g., upper respiratory infection [URI], oral and perioral infections, candidiasis, coxsackievirus, AIDS, viral hepatitis, herpes simplex virus)
- Possible causes of smell disturbance:
  - Nasal and sinus disease (e.g., allergies, rhinitis, rhinorrhea)
  - Cigarette smoking
  - Cocaine abuse (intranasal)
  - Hemodialysis
  - Radiation treatment of head and neck
  - Congenital conditions
  - Neoplasm (e.g., brain tumor, nasal polyps, intranasal tumor)
  - Systemic lupus erythematosus (SLE)
  - Bell palsy
  - Oral/perioral skin lesion
  - Damage to CN I/V

- Possible association with psychosis and schizophrenia
- Possible causes of taste loss:
  - Oral appliances
  - Dental procedures
  - Intraoral abscess
  - Gingivitis
  - Damage to CN VI, IX, or X
  - Stroke (especially frontal lobe)
- Selected medications that reportedly alter smell and taste:
  - Antibiotics: amikacin, ampicillin, azithromycin, ciprofloxacin, clarithromycin, doxycycline, griseofulvin, metronidazole, ofloxacin, tetracycline, terbinafine, & *bgr*-lactamase inhibitors
  - Anticonvulsants: carbamazepine, phenytoin
  - Antidepressants: amitriptyline, doxepin, imipramine, nortriptyline
  - Antihistamines and decongestants: zinc-based cold remedies (Zicam)
  - Antihypertensives and cardiac medications: acetazolamide, amiloride, captopril, diltiazem, hydrochlorothiazide, nifedipine, propranolol, spironolactone
  - Anti-inflammatory agents: auranofin, gold, penicillamine
  - Antimanic drugs: lithium
  - Antineoplastics: cisplatin, doxorubicin, methotrexate, vincristine
  - Antiparkinsonian agents: levodopa, carbidopa
  - Antiseptic: chlorhexidine
  - Antithyroid agents: methimazole, propylthiouracil
  - Lipid-lowering agents: statins

## *Genetics*

May be related to underlying genetically associated diseases (Kallmann syndrome, Alzheimer disease, migraine syndromes, rheumatologic conditions, endocrine disorders)

## **RISK FACTORS**

- Age >65 years

- Poor nutritional status
- Smoking tobacco products

## **GENERAL PREVENTION**

- Eat a well-balanced diet, with appropriate vitamins and minerals.
- Maintain good oral and nasal health, with routine visits to the dentist.
- Do not smoke tobacco products.
- Avoid noxious chemical exposures/unnecessary radiation.

## **Geriatric Considerations**

- Elders are at particular risk of eating spoiled food or inadvertently being exposed to natural gas leaks owing to anosmia from aging.
- Anosmia also may be an early sign of degenerative disorders and has been shown to predict increased 5-year mortality (1)[B].

## **Pediatric Considerations**

- Smell and taste disorders are uncommon in children in developed countries.
- In developing countries with poor nutrition (particularly zinc depletion), smell and taste disorders may occur.
- Delayed puberty in association with anosmia ( $\pm$  midline craniofacial abnormalities, deafness, or renal abnormalities) suggests the possibility of Kallmann syndrome (hypogonadotropic hypogonadism).

## **Pregnancy Considerations**

- Pregnancy is an uncommon cause of smell and taste loss or disturbances.
- Many women report increased sensitivity to odors during pregnancy as well as an increased dislike for bitterness and a preference for salty substances.

## **COMMONLY ASSOCIATED CONDITIONS**

URI, allergic rhinitis, dental abscesses

## **DIAGNOSIS**

Smell and taste disturbances are symptoms; it is essential to look for possible underlying causes.

## **HISTORY**

- Symptoms of URI, environmental allergies
- Oral pain, other dental problems
- Cognitive/memory difficulties
- Current medications
- Nutritional status, ovolactovegetarian
- Weight loss or gain
- Frequent infections (impaired immunity)
- Worsening of underlying medical illness
- Increased use of salt and/or sugar to increase taste of food
- Neurodegenerative disease

## **PHYSICAL EXAM**

Thorough HEENT exam

## **DIFFERENTIAL DIAGNOSIS**

- Epilepsy (gustatory aura)
- Epilepsy (olfactory aura)
- Memory impairment
- Psychiatric conditions

## **DIAGNOSTIC TESTS & INTERPRETATION**

### *Initial Tests (lab, imaging)*

Consider (not all patients require all tests)

- CBC
- Liver function tests
- Blood glucose
- Creatinine
- Vitamin B<sub>12</sub> level
- Thyroid-stimulating hormone (TSH)
- Serum IgE

- CT scanning is the most useful and cost-effective technique for assessing sinonasal disorders and is superior to an MRI in evaluating bony structures and airway patency. Coronal CT scans are particularly valuable in assessing paranasal anatomy (2)[B].

## *Follow-Up Tests & Special Considerations*

Diagnosis of smell and taste disturbances is usually possible through history; however, the following tests can be used to confirm:

- Olfactory tests
  - Smell identification test: evaluates the ability to identify 40 microencapsulated scratch-and-sniff odorants (3)[B]
  - Brief smell identification test (4)[B]
  - Taste tests (more difficult because no convenient standardized tests are presently available): Solutions containing sucrose (sweet), sodium chloride (salty), quinine (bitter), and citric acid (sour) are helpful.
  - An MRI is useful in defining soft tissue disease; therefore, a coronal MRI is the technique of choice to image the olfactory bulbs, tracts, and cortical parenchyma. Possible placement of an accessory coil (TMJ) over the nose to assist in imaging.

## **TREATMENT**

### *GENERAL MEASURES*

- Appropriate treatment for underlying cause
- Quit smoking (5)[B].
- Treatment of underlying nasal congestion with nasal decongestants and/or nasal/oral steroids (6,7,8,9)[B]
- Surgical correction of nasal blockage/nasal polyps (10)[B]
- Some drug-related smell or taste loss or dysgeusias can be reversed with cessation of the offending medication, but it may take many months (11,12,13,14)[B].
- Stop repeated oral trauma (e.g., appliances, tonguebiting behaviors).
- Proper nutritional and dietary assessment (2)[C]
- Formal dental evaluation

## *MEDICATION*

- Treat underlying causes as appropriate. Idiopathic cases will often resolve spontaneously.
- Consider trial of corticosteroids topically (e.g., fluticasone nasal spray daily to BID) and/or systemically (e.g., oral prednisone 60 mg daily for 5 to 7 days) (6)[B].
- Zinc and vitamins (A, B complex) when deficiency is suspected (15)[B]

## *ISSUES FOR REFERRAL*

- Consider referral to an otolaryngologist or neurologist for persistent cases.
- Referral to a subspecialist at a regional smell and taste center when complex etiologies are suspected

## *SURGERY/OTHER PROCEDURES*

If needed for treatment of underlying cause

## **ONGOING CARE**

### *DIET*

- Weight gain/loss is possible because the patient may reject food or may switch to calorie-rich foods that are still palatable.
- Ensure a nutritionally balanced diet with appropriate levels of nutrients, vitamins, and essential minerals.

### *PATIENT EDUCATION*

- Caution patients not to overindulge as compensation for the bland taste of food. For example, patients with diabetes may need help in avoiding excessive sugar intake as an inappropriate way of improving food taste.
- Patients with chemosensory impairments should use measuring devices when cooking and should not cook by taste.
- Optimizing food texture, aroma, temperature, and color may improve the overall food experience when taste is limited.
- Patients with permanent smell dysfunction must develop adaptive strategies for dealing with hygiene, appetite, safety, and health.
- Natural gas and smoke detectors are essential; check for proper function frequently.

- Check food expiration dates frequently; discard old food.

## PROGNOSIS

- In general, the olfactory system regenerates poorly after a head injury. Most patients who recover smell function following head trauma do so within 12 weeks of injury.
- Patients who quit smoking typically recover improved olfactory function and flavor sensation.
- Many taste disorders (dysgeusias) resolve spontaneously within a few years of onset.
- Phantosias that are flow-dependent may respond to surgical ablation of olfactory mucosa.
- Conditions such as radiation-induced xerostomia and Bell palsy generally improve over time.

## COMPLICATIONS

- Permanent loss of ability to smell/taste
- Psychiatric issues with dysgeusias and phantosmia

## Codes

&NA;

### ICD10

- R43.9 Unspecified disturbances of smell and taste
- R43.1 Parosmia

## Clinical Pearls

### &NA;

- Smell disorders are often mistaken as decreased taste by patients.
- Most smell loss is due nasal passage obstruction.
- Actual taste disorders are often related to dental problems or medication side effects.
- Gradual smell loss is very common in the elderly; extensive workup in this population may not be indicated if no associated signs/symptoms are present but may be predictive of 5-year mortality.

# Somatic Symptom (Somatization) Disorder

William G. Elder, PhD

## BASICS

### DESCRIPTION

- A pattern of one or more somatic symptoms recurring or persisting for >6 months that are distressing or result in significant disruption of daily life (1)
- Conceptualization and diagnostic criteria for somatic symptom presentations were significantly modified with the advent of *DSM-5*. Somatic symptom disorder (SSD) is similar in many aspects to the former somatization disorder, which required presentation with multiple physical complaints, no longer based on symptoms counts; current diagnosis is based on the way the patient presents and perceives his or her symptoms.
- SSD now includes most presentations that would formerly be considered hypochondriasis. Hypochondriasis has been replaced by illness anxiety disorders, which is diagnosed when the patient presents with significant preoccupation with having a serious illness in the absence of illness-related somatic complaints.
- Somatization increases disability independent of comorbidity and individuals with SSD have healthrelated functioning that is two standard deviations below the mean (1,2).
- Symptoms may be specific (e.g., localized pain) or relatively nonspecific (e.g., fatigue).
- Symptoms sometimes may represent normal bodily sensations or discomfort that does not signify serious disease.
- Suffering is authentic. Symptoms are not intentionally produced or feigned.

### EPIDEMIOLOGY

#### Incidence

- Usually, first symptoms appear in adolescence.
- Predominant sex: female > male (10:1) (1)
- Type and frequency of somatic complaints may differ among cultures, so symptom reviews should be adjusted based on culture. More frequent in cultures without western/empirical explanatory models (3).

## *Prevalence*

- Expected 2% among women and <0.2% among men (4)
- Somatization seen in up to 29% of patients presenting to primary care offices (3)
- Somatic concerns may increase, but other features of the presentation decrease such that prevalence declines after age 65 years (5).

## **ETIOLOGY AND PATHOPHYSIOLOGY**

Unknown

### *Genetics*

Consanguinity studies and single nucleotide polymorphism genotyping indicate that both genetic and environmental factors contribute to the risk of SSD (6).

## **RISK FACTORS**

- Child abuse, particularly sexual abuse, has been shown to be a risk factor for somatization.
- Symptoms begin or worsen after losses (e.g., job, close relative, or friend).
- Greater intensity of symptoms often occurs with stress.

## **COMMONLY ASSOCIATED CONDITIONS**

Comorbid with other psychiatric conditions is yet to be determined but is likely to be 20-50% with anxiety, depression, or personality disorders.

## **DIAGNOSIS**

- Determining that a somatic symptom is medically unexplained is unreliable, and it is inappropriate to diagnose a mental disorder solely because a medical diagnosis is not demonstrated. Rely on symptoms and presentation rather than ruling out medical causes in making the SSD diagnosis.
- Illness anxiety and somatic distress are independent but often co-occur.

## **HISTORY**

- One or more somatic complaints, with sometimes a grossly positive review of symptoms
- SSD involves patient excessive thoughts, feelings, or behaviors associated with symptoms or associated health concerns manifested by at least one of

the following:

- Disproportionate and persistent thoughts about the seriousness of the symptoms
- Persistent high level of anxiety about health or symptoms
- Excessive time or energy devoted to symptoms or health concerns.
- Diagnoses no longer relies on symptom counts, but common symptoms include:
  - Pain symptoms related to different sites such as head, abdomen, back, joints, extremities, chest, or rectum, or related to body functions such as menstruation, sexual intercourse, or urination.
  - GI symptoms such as nausea, bloating, vomiting (not during pregnancy), diarrhea, intolerance of several foods
  - Sexual symptoms such as indifference to sex, difficulties with erection or ejaculation, irregular menses, excessive menstrual bleeding, or vomiting throughout all 9 months of pregnancy
  - Pseudoneurologic symptoms such as impaired balance or coordination, weak or paralyzed muscles, lump in throat or trouble swallowing, loss of voice, retention of urine, hallucinations, numbness (to touch or pain), double vision, blindness, deafness, seizures, amnesia or other dissociative symptoms, loss of consciousness (other than with fainting); none of these is limited to pain.
- Patients with SSD frequently use alternative treatments, which should be explored for their effects on health and physical functioning (2).

## *PHYSICAL EXAM*

Physical exam remarkable for absence of objective findings to explain the many subjective complaints

## *DIFFERENTIAL DIAGNOSIS*

- Other psychiatric illnesses must be ruled out:
  - Depressive disorders
  - Anxiety disorders
  - Schizophrenia
  - Other somatic disorders: illness anxiety disorder, conversion disorder
  - Factitious disorder

- Body dysmorphic disorder
- Malingering
- General medical conditions, with vague, multiple, confusing symptoms, must be ruled out.
  - Systemic lupus erythematosus
  - Hyperparathyroidism
  - Hyper- or hypothyroidism
  - Lyme disease
  - Porphyria

## *DIAGNOSTIC TESTS & INTERPRETATION*

Several screening tools are available that help to identify symptoms as somatic:

- Patient Health Questionnaire (PHQ)-15 (screens and monitors symptoms) (7)[B]
- Minnesota Multiphasic Personality Inventory (MMPI) (identifies somatization) (8)[B]

### *Initial Tests (lab, imaging)*

- Laboratory test results do not support the subjective complaints.
- Imaging studies do not support the subjective complaints.

### *Test Interpretation*

None are identified.

## **TREATMENT**

### *GENERAL MEASURES*

- The goal of treatment is to help the person learn to control the symptoms (9)[B].
- A supportive relationship with a sympathetic health care provider is the most important aspect of treatment:
  - Regular scheduled appointments should be maintained to review symptoms and the person's coping mechanisms (at least 15 minutes once a month).
  - Acknowledge and explain test results.

- The involvement of a single provider is important because a history of seeking medical attention and Doctor shopping is common.
- Antidepressant or anti-anxiety medication and referral to a support group or mental health provider can help patients who are willing to participate in their treatment.
- Patients usually receive the most benefit from primary care providers who accept the limitations of treatment, listen to their patient's concerns, and provide reassurance.
- It is not helpful to tell patients that their symptoms are imaginary.

## *MEDICATION*

Antidepressants (e.g., SSRIs) help to treat comorbid depression and anxiety (10)[C].

## *ISSUES FOR REFERRAL*

- Discourage referrals to specialists for further investigation of somatic complaints.
- Referrals to support groups or to a mental health provider may be helpful.

## *ADDITIONAL THERAPIES*

Treatments have not been evaluated for this recently reformulated disorder. However, there are numerous studies with positive outcomes for patients with various forms of somatization or medically unexplained symptoms.

- Treatment typically includes long-term therapy, which has been shown to decrease the severity of symptoms.
- Individual or group cognitive-behavioral therapy addressing health anxiety, health beliefs, and health behaviors has been shown to be the most efficacious treatment for somatoform disorders. Cognitive processes modified in therapy include patient tendencies to ruminate and catastrophize (11,12,13)[A].

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Patients should have regularly scheduled followup with a primary care doctor, psychiatrist, and/or therapist.

### *PATIENT EDUCATION*

Encourage interventions that decrease stressful elements of the patient's life:

- Psychoeducational advice
- Increase in exercise
- Pleasurable private time

## PROGNOSIS

- Chronic course, fluctuating in severity
- Full remission is rare.
- Individuals with this disorder do not experience any significant difference in mortality rate or significant physical illness.
- Patients with this diagnosis do experience substantially greater functional disability and role impairment than nonsomatizing patients.

## COMPLICATIONS

- May result from invasive testing and from multiple evaluations that are performed while looking for the cause of the symptoms
- A dependency on pain relievers or sedatives may develop.

**&NA;**

## **ICD10**

- F45.9 Somatoform disorder, unspecified
- F45.20 Hypochondriacal disorder, unspecified
- F45.22 Body dysmorphic disorder

## **Clinical Pearls**

**&NA;**

- With the advent of *DSM-5*, diagnosis is now based on a pattern of symptoms rather than an absence of medical explanation.
- A clue is accumulation of several diagnoses with >13 letters (e.g., chronic fatigue syndrome, fibromyalgia syndrome, reflex sympathetic dystrophy, temporomandibular joint syndrome, carpal tunnel syndrome, mitral valve prolapse).
- Inability of more than three physicians to make a meaningful diagnosis suggests somatization.
- Acknowledge the patient's pain, suffering, and disability.
- Do not tell patients the symptoms are "all in their head."
- Emphasize that this is not a rare disorder.
- Discuss the limitations of treatment while providing reassurance that there are interventions that will lessen suffering and reduce symptoms.

# Spinal Stenosis

**N. Wilson Holland, MD, FACP, AGSF**

**Birju B. Patel, MD, FACP, AGSF**

## BASICS

### DESCRIPTION

Narrowing of the spinal canal and foramen:

- Spondylosis or degenerative arthritis is the most common cause of spinal stenosis, resulting from compression of the spinal cord by disc degeneration, facet arthropathy, osteophyte formation, and ligamentum flavum hypertrophy.
- The L4-L5 level is most commonly involved.

### EPIDEMIOLOGY

The prevalence of spinal stenosis increases with age due to wear and tear on the normal spine.

#### *Incidence*

Symptomatic spinal stenosis affects up to 8% of the general population.

#### *Prevalence*

- The prevalence of spinal stenosis can be very high if assessed solely by imaging in elderly patients. Not all patients with radiographic spinal stenosis are symptomatic. The degree of radiographic stenosis does not always correlate with patient symptoms. Lumbar MRI showed significant abnormalities in one study in 22% of asymptomatic patients <60 years and in 57% of patients >60 years. T2-weighted imaging showed a 98% prevalence of disc degeneration in asymptomatic patients >60 years (1)[C].
- Predominant age: Symptoms develop in 5th to 6th decades (congenital stenosis is symptomatic earlier) (2)[A].

### ETIOLOGY AND PATHOPHYSIOLOGY

- Spinal stenosis can result from congenital or acquired causes. Degenerative spondylosis is the most common cause.

- Disc dehydration leads to loss of height with bulging of the disc annulus and ligamentum flavum into the spinal canal, increasing facet joint loading.
- Facet loading leads to reactive sclerosis and osteophytic bone growth, further compressing spinal canal and foraminal elements.
- Other causes of acquired spinal stenosis include:
  - Trauma
  - Neoplasms
  - Neural cysts and lipomas
  - Postoperative changes
  - Rheumatoid arthritis
  - Diffuse idiopathic skeletal hyperostosis
  - Ankylosing spondylitis
  - Metabolic/endocrine causes-osteoporosis, renal osteodystrophy, and Paget disease (3)[A]

## *Genetics*

No definitive genetic links

## ***RISK FACTORS***

Increasing age and degenerative spinal disease

## ***GENERAL PREVENTION***

There is proven prevention for spinal stenosis. Symptoms can be alleviated with flexion at the waist:

- Leaning forward while walking
- Pushing a shopping cart
- Lying in flexed position
- Sitting
- Avoiding provocative maneuvers (back extension, ambulating long distances without resting)

**DIAGNOSIS**

**HISTORY**

- The history helps distinguish spinal stenosis from other causes of back pain and peripheral vascular disease.
  - Insidious onset and slow progression are typical. Discomfort with standing, paresthesias and weakness (often bilateral) (4)[C].
  - Symptoms *worsen with extension* (prolonged standing, walking downhill, or down stairs).
  - Symptoms *improve with flexion* (sitting, leaning forward while walking, walking uphill or upstairs, lying in a flexed position).
- Neurogenic claudication (i.e., pain, tightness, numbness, and subjective weakness of lower extremities) may mimic vascular claudication.
- Nocturnal leg cramps may relate to the severity of lumbar spinal stenosis (5) [C].

## PHYSICAL EXAM

Neurologic exam may be normal. Key exam areas:

- Examine gait (rule out cervical myelopathy or intracranial pathology).
- Loss of lumbar lordosis
- Evaluate range of motion of lumbar spine.
- Pain with extension of the lumbar spine is typical.
- Straight-leg raise test may be positive if nerve root entrapment is present.
- Muscle weakness is usually mild and involves the L4, L5, and (rarely) S1 nerve roots.
- About half of patients with symptomatic stenosis have a reduced or absent Achilles reflex. Some have reduced or absent patellar reflex.

## DIFFERENTIAL DIAGNOSIS

- Vascular claudication. Symptoms of vascular claudication do not improve with leaning forward and usually do not persist with standing or rest.
- Disc herniation
- Cervical myelopathy

## DIAGNOSTIC TESTS & INTERPRETATION

Generally a clinical diagnosis. Imaging (MRI is best) is used to stage severity and plan treatment.

## *Initial Tests (lab, imaging)*

- CBC, ESR, C-reactive protein (if considering infection or malignancy)
- New back pain lasting >2 weeks or back pain accompanied by neurologic findings in patients >50 years generally warrants neuroimaging.
- MRI is the modality of choice for the diagnosis of spinal stenosis.
- CT myelography is an alternative to MRI but is invasive and has higher risk of complications.
- Plain radiography helps exclude other causes of new back pain (e.g., malignant lytic lesions) but does not reveal the underlying pathology.
- Radiologic abnormalities in general do not correlate with the clinical severity (6)[C].

## *Diagnostic Procedures/Other*

Surgical decompression is the definitive option for patients who are symptomatic after nonoperative treatment:

- Spinal stenosis generally does not lead to neurologic damage.
- Surgery may be required for pain relief, allowing patients to become more mobile and improving overall health and quality of life.

## *Test Interpretation*

Common radiographic findings include decreased disc height, facet hypertrophy, and spinal canal and/or foraminal narrowing.

## **TREATMENT**

- In general, nonoperative interventions are preferred unless there are progressive or debilitating neurologic symptoms:
  - Physical therapy, exercise, weight management, lumbar epidural steroid injections, and medications are all options. There is not enough evidence in the current literature to guide definitive clinical practice.
  - Patients considering surgery should understand that the benefits of surgery may diminish over time (7)[A].
  - Rule out other neuropathies and peripheral vascular disease.
- Spinal decompression and physical therapy yield similar effects (8)[A].
- There is some controversy about whether a fusion should be performed with the

decompression because of risk of future spondylolisthesis (7)[A],(9) [C],(10)[A].

## *MEDICATION*

### *First Line*

- Acetaminophen: caution in those with preexisting liver disease; increased warnings for hepatotoxicity; limit daily dosing in the elderly.
- NSAIDs: Consider potential for GI side effects, fluid retention, and renal failure.

### *Second Line*

- Tramadol—currently a schedule IV controlled substance. Has the potential to cause confusion, dizziness, lower seizure threshold, and increase fall risk in the elderly; should be used with caution
- There is limited evidence for long-term efficacy of lumbar epidural steroid and/or anesthetic injections. Injections maybe less effective in those with more severe stenosis and those with stenosis involving >3 lumbar levels.
- Use opioids judiciously and only when other treatments have failed to control severe pain.

### *Geriatric Considerations*

- Anti-inflammatory medications should be used with caution in the elderly due to the risks of GI bleeding, fluid retention, renal failure, and cardiovascular risks.

---

P.981

- Side effects of opioids, include constipation, confusion, urinary retention, drowsiness, nausea, vomiting, and the potential for dependence.
- >10% of elderly lack Achilles reflexes.

## *ISSUES FOR REFERRAL*

Refer to a spine surgeon when patients are in unremitting pain or have a neurologic deficit.

## *ADDITIONAL THERAPIES*

- Patients with spinal stenosis are typically able to ride a bicycle because leaning forward tends to relieve symptoms.
- Aquatic therapy (helpful for muscle training and general conditioning)
- Strengthening of abdominal and back extensor muscles
- Gait training

- A brace or corset may help in the short term but is not recommended for prolonged periods due to development of paraspinal muscle weakness.
- Encourage physical activity to prevent deconditioning.

## ***SURGERY/OTHER PROCEDURES***

- Surgery is indicated when symptoms persist despite conservative measures (7)[A].
- Age alone should not be an exclusion factor for surgical intervention. Cognitive impairment, multiple comorbidities, and osteoporosis may increase the risk of perioperative complications in the elderly.
- Lumbar decompressive laminectomy is the mainstay of treatment. The traditional approach is laminectomy and partial facetectomy.
- Controversy exists about whether the decompression should be supplemented by a fusion procedure:
  - There is evidence that fusion (simple or complex), as opposed to decompression procedure alone, may be associated with higher risk of major complications, increased mortality, and increased resource use in the elderly.
- A less-invasive alternative, known as interspinous distraction (X STOP implant), is an option (11)[B].
- The evidence for use of the Aperius interspinous implant device is inconclusive (12, 13)[C].
- A unilateral partial hemilaminectomy combined with transmedial decompression may adequately treat stenosis with less morbidity in the elderly (14)[C].
- Transforaminal balloon treatment may be a viable option for resistant spinal stenosis pain and functional impairment (15)[B].

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Acute or progressive neurologic deficit

### ***Discharge Criteria***

Improved pain or after neurologic deficit has been addressed.

**ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

- Follow up based on progression of symptoms.
- No limitations to activity; patients may be as active as tolerated. Exercise should be encouraged.

## ***Patient Monitoring***

Patients are monitored for improvement of symptoms and development of any complications.

## ***DIET***

Optimize nutrition for weight management and surgery.

## ***PATIENT EDUCATION***

- Activity as tolerated, if no other pathology is present (e.g., fractures).
- Patients should present for care if they develop progressive motor weakness and/or bladder/bowel dysfunction.
- Patients should know the natural history of the condition and how best to relieve symptoms.

## ***PROGNOSIS***

- Spinal stenosis is generally benign, but the pain can lead to limitation in ADLs and progressive disability.
- Surgery usually improves pain and symptoms in patients who fail nonoperative treatment.
- Surgical outcomes are similar in terms of pain relief and functional improvement for patients of all ages.

## **COMPLICATIONS**

- Severe spinal stenosis can lead to bowel and/or bladder dysfunction.
- Surgical complications include infection, neurologic injury, chronic pain, and disability.

## See Also

**&NA;**

Algorithm: Low Back Pain, Acute

## Codes

**&NA;**

### ICD10

- M48.00 Spinal stenosis, site unspecified
- M48.06 Spinal stenosis, lumbar region
- M48.04 Spinal stenosis, thoracic region

## Clinical Pearls

**&NA;**

- Spinal stenosis often presents as neurogenic claudication (pain, tightness, numbness, and subjective weakness of lower extremities). This can mimic vascular claudication.
- Neurogenic claudication (as opposed to vascular claudication) is improved by uphill ambulation and lumbar flexion.
- Flexion of the spine generally relieves symptoms associated with spinal stenosis.
- Spinal extension (prolonged standing, walking downhill, and walking downstairs) can worsen

symptoms of spinal stenosis.

- Urgent surgery should be considered for patients with cauda equina/conus medullaris syndrome or progressive bladder dysfunction. Most other patients with lumbar spinal stenosis can begin with conservative management.

# Sprain, Ankle

Shane L. Larson, MD

## BASICS

### DESCRIPTION

The most common cause of ankle injury comprising a significant proportion of sports injuries:

- Types of ankle sprains: lateral, medial, and syndesmotic (or high ankle sprain)
  - Lateral ankle sprains are the most common, accounting for 85% of all ankle sprains:
    - In lateral ankle sprains, the anterior talofibular ligament (ATFL) is most likely to be injured.
    - The calcaneofibular ligament (CFL) is the second most likely ligament to be injured.
    - The posterior talofibular ligament (PTFL) is the least likely to be injured.
  - Medial ankle sprains (5-10%) result from an injury to the deltoid ligament.
  - Syndesmotic (or high ankle) injuries account for 5-10% of ankle sprains.
    - The syndesmosis between the distal tibia and distal fibula bones consists of the anterior, posterior, and transverse tibiofibular ligaments and the interosseous ligament and interosseous membrane.
- Ankle sprains are classified according to the degree of ligamentous disruption:
  - Grade I: mild stretching of a ligament with possible microscopic tears
  - Grade II: incomplete tear of a ligament
  - Grade III: complete ligament tear

### *Geriatric Considerations*

Increased risk of fracture in patients with preexisting bone weakness (osteoporosis/osteopenia)

### *Pediatric Considerations*

- Increased risk of physeal injuries instead of ligament sprain because ligaments have greater tensile strength than physes

- Inversion ankle injuries in children may have a concomitant fibular physeal injury (Salter Harris type I or higher fracture).
- Consider tarsal coalition with recurrent ankle sprains.

## *EPIDEMIOLOGY*

### *Incidence*

- Peak incidence in children (0 to 12 years old), then adolescents (13 to 17 years old), and finally adults (<sup>3</sup>18 years old) (1)
- 1/2 of all ankle sprains are sports-related; highest incidence in indoor/court sports (basketball, volleyball, tennis), followed by football and soccer (2)
- Most common sports injury
- More common in males age <30 years and females >30 years old

### *Prevalence*

- 25% of sports injuries in the United States
- 75% of all ankle injuries are sprains.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Lateral ankle sprains result from an inversion force with the ankle in plantar flexion.
- Medial ankle sprains are due to forced eversion while the foot is in dorsiflexion.
- Syndesmotic sprains result from eversion stress/extreme dorsiflexion along with internal rotation of tibia.

## *RISK FACTORS*

- The greatest risk factor is a prior history of an ankle sprain (3-34% recurrence rate).
- Postural instability, gait alterations
- Joint laxity and decreased proprioception are not risk factors.

## *GENERAL PREVENTION*

- Improve overall physical conditioning:
  - Training in agility and flexibility
  - Single-leg balancing

- Proprioceptive training (3)
- Taping and bracing may help prevent primary injury in selected sports (i.e., volleyball, basketball, football) or reinjury (4). Taping and bracing do not reduce sprain severity.

## COMMONLY ASSOCIATED CONDITIONS

- Contusions
- Fractures
  - Fibular head fracture/dislocation (Maisonneuve)
  - Fracture of the base of the 5th metatarsal
  - Distal fibula physeal fracture (includes Salter-Harris fractures in pediatric patients; most common type of pediatric ankle fracture)

## DIAGNOSIS

### HISTORY

- Elicit specific mechanism of injury (inversion vs. eversion)
- Popping/snapping sensation during the injury
- Previous history of ankle injuries
- Ability to ambulate immediately after the injury
- Rapid onset of pain, swelling, or ecchymosis
- Location of pain (lateral/medial)
- Difficulty bearing weight
- Past medical history of systemic disorders

### PHYSICAL EXAM

- Timing: Initial assessment for laxity may be difficult due to pain, swelling, and muscle spasm. Repeat exam ÷5 days after injury may improve sensitivity.
- Compare to uninjured ankle for swelling, ecchymosis, weakness, and laxity
- Neurovascular exam
- Palpate ATFL, CFL, PTFL, and deltoid ligament for tenderness.
- Palpate lateral and medial malleolus, base of 5th metatarsal, navicular, and entire fibula.

High ankle sprain associated with fracture of proximal fibula

- Grade I sprain: mild swelling and pain; no laxity; able to bear weight/ambulate without pain
- Grade II sprain: moderate swelling and pain; mild laxity with firm end point noted; weight bearing/ambulation painful
- Grade III sprain: severe swelling, pain, and bruising; laxity with no end point; significant instability and loss of function/motion; unable to bear weight/ambulate
  - Swelling less sensitive for grade of tear in pediatric patient
- Special tests:
  - Anterior drawer test to check for ATFL laxity
  - Talar tilt test to check laxity in CFL (with inversion) or deltoid ligament (eversion)
  - Squeeze test: Compress tibia and fibula midcalf to check for syndesmotic injury; sensitivity 30%, specificity 93.5%.
  - Dorsiflexion/external rotation test: Positive test is pain at syndesmosis with rotation; sensitivity 20%, specificity 85%.

## *DIFFERENTIAL DIAGNOSIS*

- Tendon injury
  - Tendinopathy/tendon tear
- Fracture and/or dislocation of the ankle/foot
- Hindfoot/midfoot injuries
- Nerve injury
- Contusion

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Ottawa Ankle Rules (nearly 100% sensitive, 30-50% specific) determine need for radiographs to rule out ankle fractures (patient must be 18 to 55 years; certain patients, e.g., diabetics with diminished sensation, may still need radiographs):
  - Pain in malleolar zone
  - Inability to bear weight (walk <sup>34</sup> steps) immediately and in the exam room
  - Bony tenderness at tip/posterior edge of the lateral/medial malleolus

Note: Ottawa rule for foot imaging series (reported pain in the midfoot zone AND pain with palpation of navicular or base of 5th metatarsal, OR inability to bear weight immediately and in the ER/office)

- Although Ottawa rules are highly sensitive, they should not overrule clinical judgment.
- If radiographs are indicated, obtain anteroposterior, lateral, and mortise views of the ankle.
  - Small avulsion fractures are associated with grade III sprains.
- Consider CT if radiographs are negative but occult fracture is suspected clinically.
- MRI is the gold standard for soft tissue imaging but is expensive and rarely necessary.
  - Syndesmotic ankle sprains: MRI is more sensitive.
- US is a good second line imaging option with a sensitivity comparable to MRI.

## Follow-Up Tests & Special Considerations

If patient condition does not improve in 6 to 8 weeks, consider CT, MRI, or US.

## TREATMENT

### GENERAL MEASURES

- Most grade I, II, and III lateral ankle sprains can be managed conservatively.
- Conservative therapy: PRICE (protection, relative rest, ice, compression, elevation)
- Protection/compression: For grade I/II sprains, laceup bracing is superior to air-filled/gel-filled ankle brace, which is superior to elastic bandage/taping to provide support and decrease swelling.
  - Note: The combination of air-filled brace and compression wrap is superior to each individual for return to preinjury joint function at 10 days and 1 month for grades I and II sprains (5)[A].

---

P.983

- Grade III sprains should have short-term immobilization (10 days) with below-the-knee cast, followed by a semirigid brace (air cast). If a patient refuses casting, a 10-day period of strict non-weight-bearing with air cast splint and elastic bandage is a comparable alternative if non-weight-bearing is maintained.
- Rest: Initially, activity as tolerated. Early mobilization and physical therapy speed recovery/reduce pain:

- Weight bearing, as tolerated
- Consider crutches if unable to bear weight.
- Exercises should be initiated as early as tolerated and limited to pain-free range of motion.
- Patients can start mobilization by tracing the alphabet with the foot in the air.
- Resistance exercises with an elastic band
- Ice: Ice for first 3 to 7 days for pain reduction and decrease recovery time
- Elevation: Elevate ankle to decrease swelling.

## *MEDICATION*

- NSAIDs: preferably oral; topical forms (e.g., diclofenac 1% gel) may be used to minimize GI side effects. PRN NSAID dosing has similar outcomes to scheduled dosing with improved safety profile.
  - Example: Naproxen 500 mg BID PRN
- Acetaminophen 650 mg q4-6h (max outpatient therapy dose: 3,250 mg/day)
- Opioids if severe pain

## *ISSUES FOR REFERRAL*

- Malleolar/talar dome fracture
- Syndesmotic sprain
- Dislocation/subluxation
- Tendon rupture
- Ongoing instability
- Uncertain diagnosis

## *ADDITIONAL THERAPIES*

Physical therapy:

- After the acute phase of the injury, patients with grade II or III sprain should start physical therapy as soon as possible to increase range of motion, strength, flexibility, and improve proprioceptive balance (wobble board/ankle disk).
- Functional rehabilitation prevents chronic instability and speeds healing.
- Athletes should undergo sports-specific rehabilitation before returning to play.

## ***SURGERY/OTHER PROCEDURES***

- Surgery is typically reserved for treatment of complicated recurrent sprains and certain syndesmotic sprains.
- Patients with chronic ankle instability who fail functional rehabilitation or with poor tissue quality may need anatomic repair/reconstructive surgery.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- After an ankle sprain, ankle-stabilizing orthoses (air stirrup braces, lace-up supports, athletic taping, etc.) should be worn for high-risk sports to prevent future ankle sprains.
- Moderate and severe sprains require ankle orthoses for <sup>3</sup>6 months during sports participation.
- Gradual return to play for athletes with a grade I lateral ankle sprain can generally be accomplished in 1 to 2 weeks; grade II sprain return to play time is 2 to 3 weeks; grade III sprain is approximately 4 weeks.
- Syndesmotic sprains take longer (approx. 8 to 9 weeks) to heal than lateral ankle sprains.

### ***Patient Monitoring***

If athletes continue to have symptoms when they return to play or if a patient has pain for 6 to 8 weeks after injury, repeat examination and imaging.

### ***PATIENT EDUCATION***

- Crutch training
- Provide training on proper use of elastic bandages, brace, and/or orthoses
- Demonstrate mobilization exercises (alphabet trace, towel grab).

### ***PROGNOSIS***

- Earlier physical therapy and mobilization with bracing allows for faster return to daily living and/or sports.
- Higher grade sprains, older patient age, and initial non-weight-bearing status have poorer prognosis and longer recovery.
- Ligamentous strength does not return for months after the injury.

## COMPLICATIONS

- Joint instability
- Intermittent swelling/pain if not properly treated
- Accumulation of cartilage damage, leading to degenerative changes
- 5-33% continue to have pain 1 year postinjury.

## Codes

**&NA;**

### ICD10

- S96.919A Strain of unsp msl/tnd at ank/ft level, unsp foot, init
- S93.499A Sprain of other ligament of unspecified ankle, init encntr
- S93.419A Sprain of calcaneofibular ligament of unsp ankle, init

## Clinical Pearls

**&NA;**

- Children are at an increased risk of physeal injuries because ligaments are stronger than physes.
- Conditioning, including proprioceptive training, before participating in sports and throughout the season helps to prevent ankle sprains.
- Functional rehabilitation, rather than total immobilization, is recommended for quicker return to sport and work.
- If patient's condition is not improving in 6 to 8 weeks, consider advanced imaging with CT, MRI, or US.

# Sprains and Strains

Daniel L. Jones, MD

J. Herbert Stevenson, MD

## BASICS

### DESCRIPTION

- *Sprains* are complete or partial ligamentous injuries either within the body of the ligament or at the site of attachment to bone.
  - Classified as grade 1, 2, or 3 (AMA Ligament Injury Classification)
    - Grade 1: stretch injury without ligamentous laxity
    - Grade 2: partial tear with increased ligamentous laxity but firm endpoint on exam
    - Grade 3: complete tear with increased ligamentous laxity and no firm endpoint on exam
  - Usually secondary to trauma (e.g., falls, twisting injuries, motor vehicle accidents)
  - Physical exam is the key to accurate diagnosis.
- *Strains* are partial or complete disruptions of the muscle, muscle-tendon junction, or tendon
  - Classified as
    - First degree: minimal damage to muscle, tendon, or musculotendinous unit
    - Second degree: partial tear to the muscle, tendon, or musculotendinous unit
    - Third degree: complete disruption of the muscle, tendon, or musculotendinous unit
  - Often associated with overuse injuries

### *Geriatric Considerations*

More likely to see associated bony injuries due to decreased joint flexibility and increased prevalence of osteoporosis and osteopenia

### *Pediatric Considerations*

- Sprains and strains account for 24% of pediatric injuries.

- 3 million pediatric sports injuries occur annually.
- Must be concerned about physeal/apophyseal injuries in the skeletally immature patient

## *EPIDEMIOLOGY*

### *Incidence*

÷80% of all U.S. athletes experience a sprain or strain at some point.

### *Prevalence*

- Ankle sprains are among the most common injuries in primary care, accounting for ÷30% of sports medicine clinic visits. Most ankle sprains are due to inversion injuries (lateral sprains) involving the anterior talofibular ligament. Account for 650,000 annual ER visits in the United States (1)
- Predominant age
  - Sprains: any age in physically active patient
  - Strains: usually 15 to 40 years of age
- Predominant sex: male > female for most; female > male for sprain of acromioclavicular ligament

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Trauma, falls, motor vehicle accidents
- Excessive exercise; poor conditioning
- Improper footwear
- Inadequate warm-up and stretching before activity
- Prior sprain or strain

## *RISK FACTORS*

- Prior history of sprain or strain is greatest risk factor for future sprain/strain.
- Change in or improper footwear, protective gear, or environment (e.g., surface)
- Sudden increase in training schedule or volume.
- Tobacco use

## *GENERAL PREVENTION*

- Appropriate warm-up and cool-down exercises
- Use proper equipment and footwear.
- Balance training programs improve proprioception and reduce the risk of ankle sprains (2)[B].
- Semirigid orthoses or air casts may prevent ankle sprains during high-risk sports, especially in athletes with history of sprain (3)[A].
- Proprioception and strength training decrease injury risk, stretching does not (4)[A].

## COMMONLY ASSOCIATED CONDITIONS

- Effusions, hemarthrosis
- Stress, avulsion, or other fractures
- Syndesmotic injuries
- Contusions
- Dislocations/subluxations

## DIAGNOSIS

### HISTORY

- Obtain thorough description of mechanism of injury including activity, trauma, baseline conditioning, and prior musculoskeletal injuries.
- May describe feeling or hearing pop or snap

## PHYSICAL EXAM

- Inspect for swelling, asymmetry, ecchymosis and gait disturbance.
- Palpate for tenderness.
- Evaluate for decreased range of motion (ROM) of joint and joint instability.
- Evaluate for strength.
- Sprains
  - Grade 1: tenderness without laxity; minimal pain, swelling; little ecchymosis; can bear weight
  - Grade 2: tenderness with increased laxity on exam but firm endpoint; more pain, swelling; often ecchymosis; some difficulty bearing weight

Grade 3: tenderness with increased laxity on exam and no firm end point; severe pain, swelling; obvious ecchymosis; difficulty bearing weight

## ***DIFFERENTIAL DIAGNOSIS***

- Tendonitis
- Bursitis
- Contusion
- Hematoma
- Fracture
- Osteochondral lesion
- Rheumatologic process

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Ankle
  - Anterior drawer test assesses integrity of anterior talofibular ligament.
  - Talar tilt test assesses integrity of calcaneofibular ligament.
  - Squeeze test assesses for syndesmotic injury.
  - Palpate fibular head.
- Knee
  - Lachman test assesses integrity of anterior cruciate ligament. Posterior drawer assesses integrity of posterior cruciate ligament.
  - Valgus/varus stress tests assess integrity of medial and lateral collateral ligaments, respectively.
- Shoulder
  - Positive apprehension test may indicate glenohumeral ligament sprain.
- Radiographs help rule out bony injury; stress views may be necessary. Obtain bilateral radiographs in children to rule out growth plate injuries.
- Use Ottawa foot and ankle rules (age 18 to 55 years) to determine if radiographs are necessary (5)[A].
- Ankle films: required if pain in the malleolar zone *and*

- Bone tenderness in posterior aspect distal 6 cm of tibia *or* fibula *or*
- Unable to bear weight immediately or in emergency department
- Foot films: required if midfoot zone pain is present *and*
  - Bone tenderness at base of 5th metatarsal *or*
  - Bone tenderness at navicular *or*
  - Inability to bear weight immediately or in emergency department

## Follow-Up Tests & Special Considerations

- CT scan if occult fracture is suspected
- MRI is the gold standard for imaging soft tissue structures, including muscle, ligaments, and intraarticular structures. If tibiofibular syndesmotic disruption is suspected, MRI is highly accurate for diagnosis.

## Diagnostic Procedures/Surgery

Surgery may be required for some partial and complete sprains depending on location, mechanism, and chronicity.

## TREATMENT

### GENERAL MEASURES

- Acute: Protection, relative rest (activity modification), *ice*, compression, elevation, *medications*, modalities (PRICEMM) therapy
- Ankle sprains: Compression stockings didn't affect pain, swelling, or time to pain-free walking but did show decreased time to return to sport (6)[B].
- Grade 1, 2 ankle sprain: functional treatment with brace, orthosis, taping, elastic bandage wrap
  - Ankle braces (lace-up, stirrup-type, air cast) are a more effective functional treatment than elastic bandages or taping (7)[A].

---

P.985

- Grade 3 ankle sprain: Short period of immobilization may be needed.
- Refer for early physical therapy (8)[A].
- For high-level athletes with more extensive damage (e.g., biceps or pectoralis disruption),

consider surgical referral.

## *MEDICATION*

### *First Line*

- Acetaminophen: not to exceed 3 g/day
- NSAIDs
  - Ibuprofen: 200 to 800 mg TID
  - Naproxen: 250 to 500 mg BID
  - Diclofenac: 75 mg BID
- Opioids may be needed acutely for severe pain.
- Acetaminophen and NSAIDs have similar efficacy in reducing pain after soft tissue injuries with less GI side effects, NSAIDs were better than narcotics (9)[B].
- Topical diclofenac, ibuprofen, ketoprofen are effective for pain related to strains and sprains, especially in gel form or patch (10)[A].
- Platelet-rich plasma injections may aid recovery in treatment of muscle strains, but more studies are needed.

## *ISSUES FOR REFERRAL*

- ACL sprain in athletes/physically active
- Salter-Harris physeal fractures
- Joint instability especially chronic
- Tendon disruption (i.e., Achilles, biceps, ACL)
- Lack of improvement with conservative measures

## *ADDITIONAL THERAPIES*

- Physical therapy is a useful adjunct after a sprain, particularly if early mobilization is crucial.
  - Proprioception retraining
  - Core strengthening
  - Eccentric exercises
  - Thera-Band exercises

- After hamstring strain, frequent daily stretching and progressive agility and trunk stabilization exercises may speed recovery and reduce risk of reinjury (11)[A]. Rehab protocols emphasizing eccentric/lengthening exercises are more effective than conventional exercises (12)[B].

## ***SURGERY/OTHER PROCEDURES***

- Casting and surgery are reserved for select partial and complete sprains. Need for surgery depends on the neurovascular supply to the injured area as well as the ability to attain full ROM and stability of the affected joint. The need for surgery also depends on activity level and patient preference.
- For primary management of acute lateral ankle sprains, there is no difference between surgical versus conservative therapy. Risks are increased with surgical intervention (1)[A].

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

If the affected joint has full strength and ROM, the patient can advance activity as tolerated using pain as a guide for return to activity.

### ***Patient Monitoring***

After initial treatment, consider early rehabilitation. Limit swelling and provide pain-free, full ROM.

### ***DIET***

Weight loss if obese

### ***PATIENT EDUCATION***

- Injury prevention through proprioceptive training and physical therapy
- ROM and strengthening exercises to restore functional capacity

### ***PROGNOSIS***

Favorable with appropriate treatment and rest. Duration of recovery depends on the severity of injury.

### **COMPLICATIONS**

- Chronic joint instability
- Arthritis

- Muscle contracture

### ICD10

- S93.409A sprain of unsp ligament of unspecified ankle, init encntr
- S96.919A Strain of unsp msl/tnd at ank/ft level, unsp foot, init
- S43.50XA Sprain of unspecified acromioclavicular joint, initial encounter

## Clinical Pearls

&NA;

For acute injury, remember PRICEMM:

- Protection of the joint
- Relative rest (activity modification)
- Apply ice
- Apply compression
- Elevate joint
- Medications for pain
- Other modalities as needed

# Squamous Cell Carcinoma, Cutaneous

Mercedes E. Gonzalez, MD, FAAD

Herbert P. Goodheart, MD

## BASICS

- Squamous cell carcinoma (SCC) is a malignant epithelial tumor arising from epidermal keratinocytes. Cutaneous (nonmucous membrane) SCC is the second most common form of skin cancer.
- Lesions most frequently occur on sun-exposed sites of elderly, fair-skinned individuals. Most SCCs arise in actinic keratoses (*solar keratoses*). SCCs that develop from actinic keratoses are slow-growing, minimally invasive, and unaggressive. Thus, the prognosis of an SCC arising from an actinic keratosis is usually excellent because distant metastases are extremely rare.
- An SCC may also appear de novo without a preceding actinic keratosis or emerge from a preexisting human papillomavirus (HPV) infection (*verruccous carcinoma*).
- SCCs may develop from causes other than sun exposure such as within an old burn scar or on sites previously exposed to ionizing radiation.
- Metastases are more likely to occur in thicker tumors >6-mm deep (1). Other risk factors for metastases include lesions that arise on the ears, the vermilion border of the lips, or on mucous membranes. An SCC located on sites that received ionizing radiation on the skin of organ transplant recipients, in chronic inflammatory lesions (e.g., discoid lupus erythematosus), in long-standing scars or cutaneous ulcers (e.g., venous stasis ulcers), or other nonhealing wounds, also have an increased rate of metastasis.
- System(s) affected: skin/exocrine
- Synonym(s): squamous cell carcinoma of the skin; epidermoid carcinoma; prickle cell carcinoma

## EPIDEMIOLOGY

- Predominant age: elderly population
- Predominant sex: males >females
- In the United States, >700,000 new cases each year

## *Incidence*

- The escalating incidence in the United States is due to an increase in sun exposure in the general population, aging of the population, earlier and more frequent diagnosis of SCC, and the increase of immunosuppressed patients.
- The incidence is highest in Australia and in the Sun Belt of the United States.

### **ALERT**

Bowen disease (SCC in situ) and frank SCC are two of the few skin cancers that should be considered in African Americans. Such non-sun-related SCCs tend to arise on the extremities de novo, in an old scar, or in a lesion of discoid lupus erythematosus.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Exact mechanisms are not established; however, SCC is thought to arise from a multistep process that begins with a single mutated keratinocyte.
- UV radiation damages skin cell nucleic acids (DNA), resulting in a mutant clone of the tumor suppressor gene, *p53*. This leads to an uncontrolled growth of skin cells containing a mutated *p53* gene. Additional mutations in genes controlling cellular proliferation and/or death lead to squamous cell dysplasia, which then progresses to SCC in situ and later invasive SCC that has the potential for metastasis.
- Cumulative UV radiation (including tanning salons, and psoralen-UV-A [PUVA] phototherapy) over a lifetime is the major etiologic factor in SCC (2)[A].
- A high prevalence of HPV DNA from SCC tissue has been noted in immunocompromised as well as immunocompetent specimens of SCC tissue (3).
- Other causative agents: ionizing radiation exposure, inorganic arsenic exposure, coal tar, and other oil derivatives
- Immunosuppression by medications or disease such as HIV/AIDS

## *Genetics*

- Persons of Irish or Scottish ancestry have the highest prevalence of SCC.
- Caucasians with the red hair/fair skin phenotype (associated with certain variant alleles of the human melanocortin-1 receptor [MC1R]) are predisposed to SCC.
- SCC is rare in people of African and Asian descent, although it is the most common form of skin cancer in these populations.

## *RISK FACTORS*

- Older age
- Male sex: However, incidence is increasing in females due to lifestyle changes (e.g., suntan parlors, shorter dresses).
- Chronic sun exposure: SCC is noted more frequently in those with a greater degree of outdoor activity (e.g., farmers, sailors, gardeners).
- Patients with multiple actinic keratoses
- Personal or family history of skin cancer
- Northern European descent
- Fair complexion, fair hair, light eyes
- Poor tanning ability, with tendency to burn
- Organ transplant recipients, chronic immunosuppression
- Exposure to chemical carcinogens (e.g., arsenic, tar) or ionizing radiation
- Smoking (4)
- Therapeutic UV and ionizing radiation exposure
- Defects in cell-mediated immunity related to lymphoproliferative disorders (chronic lymphocytic leukemia [CLL], lymphoma)
- HPV infection
- Chronic scarring and inflammatory conditions
- Specific genodermatoses (e.g., xeroderma pigmentosum, oculocutaneous albinism, and dystrophic epidermolysis bullosa)

## *GENERAL PREVENTION*

Sun-avoidance measures: sunscreens, hats, clothing, and sunglasses with UV protection; tinted windshields and side windows in cars; sun-protective garments

## *COMMONLY ASSOCIATED CONDITIONS*

- Some investigators consider an actinic keratosis to be an early SCC, although relatively few ultimately are found to develop into an SCC.
- Actinic cheilitis and leukoplakia of the mucous membranes of the lips
- Cutaneous horn (see following discussion)

Xeroderma pigmentosum albinism

- Immunosuppression
- Chronic skin ulcers, preexisting scars, burns

## DIAGNOSIS

### *PHYSICAL EXAM*

Lesions occur chiefly on chronically sun-exposed areas.

- Face and backs of the forearms and hands
- Bald areas of the scalp and top of ears in men
- The sun-exposed  $\text{OV}\text{O}$  of the neck as well as the posterior neck below the occipital hairline
- In elderly females, lesions tend to occur on the legs and other sun-exposed locations.
- In African Americans, equal frequency in sunexposed and unexposed areas
- Clinical appearance
  - Generally slow-growing, firm, hyperkeratotic papules, nodules, or plaques
  - Most SCCs are asymptomatic, although bleeding, pain, and tenderness may be noted.
  - Lesions may have a smooth, verrucous, or papillomatous surface.
  - Varying degrees of ulceration, erosion, crust, or scale
  - Color is often red to brown, tan, or pearly (indistinguishable from basal cell carcinoma).
- Clinical variants of SCC
  - Bowen disease (SCC in situ): solitary lesion that resembles a scaly psoriatic plaque
  - Invasive SCC: often a raised, firm papule, nodule, or plaque. Lesions may be smooth, verrucous, or papillomatous, with varying degrees of ulceration, erosion, crust, or scale.
  - Cutaneous horn: SCC with an overlying cutaneous horn. A cutaneous horn represents a thick, hard, fingernail-like keratinization produced by the SCC. Bowen disease may also produce a cutaneous horn on its surface.
  - Erythroplasia of Queyrat refers to Bowen disease of the glans penis, which manifests as one or more velvety red plaques.
  - Subungual SCC appear as hyperkeratotic lesions under the nail plate or on surrounding periungual skin, often mimicking warts (5).

- Marjolin ulcer: an SCC evolving from a new area of ulceration or elevation at site of a scar or ulcer
- HPV-associated SCC: virally induced. An SCC most commonly seen as a new or enlarging warty growth on penis, vulva, perianal area, or periungual region
- Verrucous carcinoma: subtype of SCC that is extremely well differentiated, can be locally destructive, but rarely metastasizes. Lesions are cauliflower-like verrucous nodules or plaques.
- Basaloid SCC: less common than typical SCC; seen more often in men aged 40 to 70 years

## **ALERT**

Subungual SCC: Such lesions typically mimic warts.

## ***DIFFERENTIAL DIAGNOSIS***

- Actinic keratosis: Early SCC lesions may be clinically difficult, if not impossible, to distinguish from a precursor actinic keratosis.
- Basal cell carcinoma may be indistinguishable from an SCC, particularly if the lesion is ulcerated.
- Keratoacanthoma: This lesion also may be clinically and histopathologically impossible to differentiate from an SCC; it is considered by some to be a lowgrade variant of an SCC.
- Verruca vulgaris: The appearance of common warts is often similar to that of SCC lesions.
- Seborrheic keratosis
- Pyoderma gangrenosum
- Venous stasis ulcer
- Chemical or thermal burn

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Surgical biopsy to ensure diagnosis: shave, punch, excisional, or incisional biopsy
- 
- Sentinel lymph node biopsy rarely is used to identify micrometastases in patients with high-risk SCC and clinically negative nodes. Whether the early detection of lymph node metastasis leads to enhanced survival in SCC is unknown.
  - Patients with lymphadenopathy should be evaluated for metastases with CT scanning, MRI,

US, or PET.

## *Test Interpretation*

- Noninvasive SCC is characterized by an intraepidermal proliferation of atypical keratinocytes. Hyperkeratosis, acanthosis, and confluent parakeratosis are seen within the epidermis. Cellular atypia, including pleomorphism, hyperchromatic nuclei, and mitoses are prominent. Atypical keratinocytes may be found in the basal layer and often extend deeply down the hair follicles, but they do not invade the dermis.
- In the in situ type of SCC (Bowen disease), atypia involves the full thickness of the epidermis but the basement membrane remains intact.
- An invasive SCC penetrates through the basement membrane into the dermis. It has various levels of anaplasia and may manifest relatively few to multiple mitoses and display varying degrees of differentiation, such as keratinization.
- Poorly differentiated tumors are clinically more aggressive. SCCs proliferate first by local invasion. Metastases, when they do occur, spread via local lymph ducts to local lymph nodes.

### **ALERT**

Melanoma: An amelanotic melanoma and ulcerated melanoma may also be impossible to distinguish from an SCC.

## **TREATMENT**

### *MEDICATION*

#### *First Line*

- Total excision: preferred method for SCCs, permitting histologic diagnosis of the tumor margins
- Electrodesiccation and curettage (ED&C)
  - Best for small lesions (generally <1 cm) on flat surfaces (e.g., forehead, cheek) and SCC in situ (Bowen disease). ED&C may be used to treat superficially invasive SCCs that lack high-risk characteristics, but it is not appropriate for certain high-risk anatomic locations.
- Cryosurgery with LN<sub>2</sub> in selected lesions, such as SCC in situ
- Micrographic (Mohs) surgery is a microscopically controlled method of removing skin cancers that allows for controlled excision and maximum preservation of normal tissue. It has the highest cure rate (94-99%) of all surgical treatments. Mohs surgery may be indicated for the following:

- Large, recurrent or invasive SCCs (e.g., to bone or cartilage)
  - Lesions with a poorly delineated clinical border
  - Locations where preservation of normal tissue is extremely important (e.g., tip of the nose, eyelids, ala nasi, ears, lips, and glans penis)
- Radiation therapy is a primary treatment option that is generally restricted to older patients who are physically debilitated or are unable to undergo or refuse to undergo excisional surgery.

## *Second Line*

- Immunotherapy with topical imiquimod (Aldara) 5% cream has been successfully used for the treatment of SCC in situ (Bowen disease), actinic keratoses, genital warts, and superficial basal cell carcinomas (6)[A].
- Topical chemotherapy: topical formulations of 5-fluorouracil (5-FU) (6)[A]
- Intralesional 5-FU and bleomycin has also been used successfully to treat SCCs.
- Photodynamic therapy (PDT): PDT involves application of a photosensitizer (given topically or systemically) followed by exposure to a light source. Used primarily to treat large numbers of solar keratoses and is not recommended for treatment of invasive SCCs.
- In patients with multiple or recurrent SCCs or those at high risk, such as organ transplant recipients, chemoprevention with systemic retinoids, such as acitretin, may be effective for reducing the number of new SCCs, treating existing SCCs, and reducing the risk of recurrence.

## **ADDITIONAL THERAPIES**

For metastatic SCC, oral 5-FU has been used alone or in combination with SC interferon. More recently, epidermal growth factor receptor (EGFR) inhibitors, such as cetuximab (7)[C], are used in combination with systemic chemotherapy for metastatic disease.

## **SURGERY/OTHER PROCEDURES**

- Complete lymphadenectomy of the draining nodal basin for high-risk tumors
- Metastatic disease requires aggressive management by a multidisciplinary team, involving plastic, ENT/maxillofacial, general and oncologic surgeons.

**ONGOING CARE**

## **FOLLOW-UP RECOMMENDATIONS**

## *Patient Monitoring*

Skin exam every month for 3 months, 6 months after treatment, and then yearly

## **PATIENT EDUCATION**

Skin self-exam: Encourage sun-avoidance techniques, protective clothing, sunscreens, and so forth. Artificial tanning devices should be avoided.

## **PROGNOSIS**

- For low-risk SCCs: a 90-95% cure rate with appropriate treatment
- Overall, head and neck lesions have better prognosis; however, lip and ear lesions metastasize more frequently when compared with other sites.
- The ability to produce scale (*keratinization*) indicates a tendency for a lesion to be more differentiated and less likely to metastasize.
- Softer, nonkeratinizing lesions are not as well differentiated and thus are more likely to spread.
- Lesions  $\geq 2$  cm are more likely to recur.
- SCCs that arise in areas of non-sun-exposed skin or have a greater tendency to metastasize
- An SCC arising on a mucous membrane or in a chronic ulcer should be regarded as potentially metastatic.
- Recurrence rate and mortality is greater in immunosuppressed patients, especially solid-organ transplant recipients.
- SCCs that are deeply invasive ( $\geq 6$  mm in SC fat), or have perineural involvement, are more likely to metastasize.
- When SCC does metastasize, it usually occurs within several years from the time of diagnosis and involves draining lymph nodes.
- Once nodal metastasis of cutaneous SCC has occurred, the overall 5-year survival rate has historically been in the range of 25-35%.

## **COMPLICATIONS**

- Untreated, an SCC becomes indurated, with a tendency to ooze, ulcerate, or bleed.
- Local recurrence
- Metastatic disease

**&NA;**

## **ICD10**

- C44.92 Squamous cell carcinoma of skin, unspecified
- C44.320 Squamous cell carcinoma of skin of unspecified parts of face
- C44.42 Squamous cell carcinoma of skin of scalp and neck

## **Clinical Pearls**

**&NA;**

- SCCs that develop from actinic keratoses are generally unaggressive.
- Unlike most basal cell carcinomas, SCCs of the skin are associated with a risk of metastasis, especially those arising on mucous membranes, chronic ulcers, or in immunocompromised patients.
- A subungual SCC can easily be mistaken for a wart.

# Stevens-Johnson Syndrome

Matthew A. Silva, PharmD, RPh, BCPS

Pablo I. Hernandez Itriago, MD, MS, FAAFP

## BASICS

### DESCRIPTION

- A generalized hypersensitivity reaction, usually to a drug, in which skin and mucous membrane lesions are an early manifestation
- A severe form of erythema multiforme in which >1 mucosal surface is involved; many now consider it to be a different disease with a more difficult course and a more ominous prognosis.
- Stevens-Johnson syndrome (SJS) exists on a continuum with toxic epidermal necrolysis (TEN).
- SJS presents with characteristic targetoid cutaneous lesions when <10% of the body surface area (BSA) is involved.
- Targetoid cutaneous lesion involvement of 10-30% of BSA is considered an overlap between SJS and TEN. Involvement of >30% of BSA is TEN, which has a high morbidity and up to 70% mortality.
- System(s) affected: cardiovascular, hematologic, lymphatic/immunologic, nervous, renal/urologic, skin/exocrine
- Synonym(s): ectodermosis erosiva pluriorificialis; febrile mucocutaneous syndrome; herpes iris; erythema polymorphe; toxic epidermal necrolysis (TEN)

### ALERT

Patients with discrete skin lesions and >10% epidermal detachment are at risk of rapid progression to TEN.

### Geriatric Considerations

TEN has a greater mortality in older patients.

### Pediatric Considerations

Rare in children <3 years of age, more common in years 3 to young adult

## *Pregnancy Considerations*

Pregnancy is a possible predisposing condition.

## *EPIDEMIOLOGY*

### *Incidence*

- Incidence/prevalence of SJS in the United States is difficult to estimate because there is no universally accepted definition of SJS.
- 1.1 to 7.1 and 0.4 to 1.2 cases/1 million personyears for SJS and TEN, respectively

### *Prevalence*

- Predominant sex: male > female (2:1)
- Sex (females): 33-62% for SJS and 61.3-64.3% for TEN
- Age (average range): 25 to 47 years for SJS and 46 to 63 years for TEN, <10% of cases are children.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- 50% of cases are idiopathic; cross-reactivity between drug classes is suspected (1).
- Associated with abnormal metabolism and clearance of drugs and metabolites (2)
- Slow intrinsic acetylation rates
- 75% of cases involving SJS/TEN including those with overlap associated with a recent medication:
  - 50% of cases occur within 4 weeks and 90% of cases occur within 8 weeks of an offending agent (1).
- Algorithm-based approach is helpful for assessing probability of drug causality in SJS, TEN, or overlap (3)[B],(4).
- Frequently associated with upper respiratory tract infection and recent use of antibiotics
- Sulfonamides are the drugs most strongly associated with SJS and TEN. Then:
  - Cephalosporins
  - Quinolones
  - Aminopenicillins
  - Tetracyclines

- Macrolides
  - Imidazole antifungals
  - Antiretrovirals (e.g., protease inhibitors, efavirenz, abacavir, amprenavir, telaprevir, fosamprenavir, atazanavir, darunavir, etravirine)
  - Anticonvulsants, especially carbamazepine
  - NSAIDs, especially oxycam
  - Allopurinol, especially in patients of European/Israeli heritage
  - Acetaminophen
  - Vaccines: DPT, BCG, oral polio
  - *Mycoplasma pneumoniae* infection
- Erythematous papular lesions and keratinocyte necrosis are a consequence of cell-mediated immunity.
  - Occurs 1 to 2 weeks after initial exposure to offending drugs and within 48 hours on rechallenge
  - Accumulation and binding of reactive drug metabolites to mucocutaneous epithelial cells as haptens (3)
  - Drug haptens signal drug-specific CD8+ T-lymphocyte and macrophages, which infiltrate and express interleukin 2 (IL-2), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), and interferon- $\gamma$ , leading to keratinocyte activation.
  - Cytokines enhance keratinocyte expression of soluble Fas ligand and Fas receptors, leading to apoptosis.

## Genetics

Associations with *HLA-A\*3101* in Northern Europeans; *HLA-B\*1501*, *HLA-B\*1502*, *HLA-B\*1511*, *HLA-B\*5801* in patients of Asian ancestry, *HLA-Bw44*, *HLA-B12*, and *HLA-DQB1\*0601*

## RISK FACTORS

- Previous history of SJS
- Immunocompromised status, including chronic viral infections with Epstein-Barr virus and HIV (5)
- Patients with HIV infection may be predisposed to developing SJS in response to their medications:

- HLA allele subtypes A, B, and D
- Diseases that cause immune compromise (e.g., deficiencies, malignancy)
- Possibly radiation therapy/ultraviolet light

## GENERAL PREVENTION

Secondary prevention possible by avoiding exposure to offending medications/chemical agents.

## COMMONLY ASSOCIATED CONDITIONS

- SJS progressing to TEN is ominous prognostically.
- *M. pneumoniae* may be an infectious precursor.

## DIAGNOSIS

### HISTORY

- Usually a preceding illness for which the medication was given 1 to 3 weeks before initial cutaneous manifestations
- Sudden onset with rapidly progressive pleomorphic rash that includes petechiae, vesicles, bullae
- Considered to be SJS if epidermal detachments affect <10% of the skin
- Classified as TEN if epidermal detachments affect >30% or >10% in the absence of discrete skin lesions
- Discrete skin lesions and 10-30% epidermal detachment are an overlap between SJS/TEN.
- Burning sensation of the skin and sometimes of the mucous membranes
- Usually no pruritus
- Fever 39-40°C (102-104°F)
- Headache, malaise, arthralgias
- Cough productive of thick, purulent sputum

## PHYSICAL EXAM

- Recognized by the presence of several of the following features:
  - Vesicles and ulcers on the mucous membranes, especially the mouth and throat
  - Confluent erythematous macules with purpuric, necrotic centers and overlying blistering (1)

- Epidermal detachment with light lateral pressure (Nikolsky sign)
- Fever 39-40°C (102-104°F)
- Crusted nares
- Conjunctivitis and/or corneal ulcerations
- Erosive vulvovaginitis/balanitis
- Cough productive of thick, purulent sputum
- Tachypnea/respiratory distress
- Arrhythmias
- Pericarditis
- Congestive heart failure (CHF)
- Mental status changes
- Seizures
- Coma
- Sepsis:
  - May be seen in SJS when epidermal detachment affects <10% of the skin
  - Seen in TEN if epidermal detachment >30% or >10% in the absence of discrete skin lesions

## *DIFFERENTIAL DIAGNOSIS*

- Erythema multiforme major
- Exfoliative dermatitis
- Linear IgA bullous dermatosis
- Staphylococcal scalded skin syndrome
- Pemphigus (paraneoplastic)
- Generalized fixed drug eruption
- Burns
- Pressure blisters (coma, barbiturates)

## *DIAGNOSTIC TESTS & INTERPRETATION*

## *Initial Tests (lab, imaging)*

- Culture/serologic tests for suspected sources of infection
- Electrolytes and creatinine
- Urine for albuminuria/hematuria

## *Follow-Up Tests & Special Considerations*

Skin biopsy

## **TREATMENT**

### *GENERAL MEASURES*

- Withdraw all suspected medications, and treat any underlying disease.
- Meticulous care of damaged skin
- Supportive care, including moisture-retentive ointment, petroleum jelly, and sterile saline compresses
- Catheter changing and culturing
- Reverse isolation and temperature control with extensive epidermal loss
- Maintenance of fluid, electrolyte, and protein balance
- Plasmapheresis
- Adequate calorie intake; parenteral nutrition, if necessary
- Mouthwashes of warm saline or a solution of diphenhydramine, lidocaine, and kaolin suspension
- Ophthalmologic consultation and monitoring for corneal damage
- Venous thromboembolism prophylaxis with unfractionated heparin or low-molecular-weight heparin

### *MEDICATION*

#### *First Line*

- Corticosteroids are controversial. Early high-dose IV steroids may attenuate disease progression, reduce skin detachment, decrease inflammatory cytokine activity, and improve patient comfort. Withdraw if no benefit is seen in the 1st few days.

- Experimental treatments that appear to have been useful include:
  - Recombinant granulocyte colony-stimulating factor
  - Cyclophosphamide
  - Cyclosporine (6)
  - Intravenous immunoglobulin (IVIG) in HIV-positive patients; IVIG is considered beneficial treatment and prophylaxis, although not approved by the FDA (5). Interferes with Fas ligand-induced apoptosis.
- Contraindications: Avoid steroids in diabetic/immunosuppressed patients/those with chronic infections.

## *Second Line*

- Acyclovir for herpetic infections
- Erythromycin or related antibiotic for *Mycoplasma* infections (empirical use of antibiotics is not recommended)

## **ADDITIONAL THERAPIES**

In severe ocular surface and eyelid inflammation due to acute SJS and TEN, amniotic membrane transplantation is an effective treatment for severe ocular surface and eyelid inflammation, greatly decreasing the risk of significant ocular and visual sequelae.

## **SURGERY/OTHER PROCEDURES**

- Sterile débridement of areas of extensive epidermal loss
- Application of biosynthetic dressings, such as Biobrane to denuded areas
- Damage to the vulva, vagina, or cornea: Consider surgical repair.

## **INPATIENT CONSIDERATIONS**

### *Admission Criteria/Initial Stabilization*

- This disease progresses rapidly; all patients should be admitted.
- Admission to a burn unit greatly improves the outcome for any patient who has sloughed skin over <sup>3</sup>10% of the BSA.
- ICU for bronchiolitis, acute respiratory distress syndrome (ARDS), or multiorgan damage

### *IV Fluids*

Fluid management with saline and macromolecules is necessary in the first 24 hours with decreasing IV fluid requirements as oral intake proceeds with nasogastric tube.

## *Nursing*

- Bed rest until clinically stabilized
- Avoid administration of topical silver sulfadiazine owing to association with sulfonamide and SJS.
- Use a coordinated approach involving critical care, wound care, and burn specialists (1).

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Extensive documentation of all offending/suspected medications/chemical agents
- Education to limit exposure to offending/suspected medications/chemical agents

### *DIET*

IV nutritional support with increased protein requirements; may need insulin for glycoregulation in this hypercatabolic state

### *PATIENT EDUCATION*

Plan to prevent exposure to offending/suspected medications/agents.

### *PROGNOSIS*

- Rapid onset or evolve over 1 to 2 weeks with resolution over 4 to 6 weeks.
- Often skin/mucous membrane scarring occurs, especially of the vulva
- Blindness/corneal opacities occur in 7-20% of patients.
- Risk of recurrence is as high as 37%.

### **COMPLICATIONS**

- Secondary infections, sepsis, pneumonia, ARDS
- Bronchiolitis obliterans in children
- Dehydration/electrolyte disturbance, acute tubular necrosis
- Corneal ulceration/iritis, urethral erosions, and genitourinary strictures
- Arrhythmias

- Venous thromboembolism, disseminated intravascular coagulation DIC
- Death occurs in 5-15% of the patients with SJS, up to 30% in patients with SJS/TEN overlap, and in up to 50% of patients with TEN (7).

## Codes

**&NA;**

## **ICD10**

- L51.1 Stevens-Johnson syndrome
- L51.3 Stevens-Johnson synd-tox epdrml necrolysis overlap syndrome

## **Clinical Pearls**

**&NA;**

- Corticosteroid treatment is controversial. If chosen and no response within 1st few days, discontinue.
- Recurrences are possible. Etiologic agents should be identified if possible and avoided indefinitely.

# Stress Fracture

Nandhini Veeraraghavan, MD, CAQSM

## BASICS

### *DESCRIPTION*

- Overuse injuries caused by cumulative microdamage from repetitive bone loading.
- Stress fractures occur in different situations:
  - Fatigue fracture: abnormal stress applied to normal bone (e.g., young college athletes or new military recruits with increased physical activity demands and inadequate conditioning)
  - Insufficiency fracture: normal stress applied to structurally abnormal bone (e.g., femoral neck fracture in osteopenic bone)
  - Combination fracture: abnormal stress applied to abnormal bone (e.g., female long-distance runners with premature osteoporosis from female athletic triad)
- Weight-bearing bones of the lower extremity are most commonly affected at the following sites:
  - Tibia
  - Metatarsal bones
  - Fibula
  - Navicular
  - Femoral neck
  - Pars interarticularis
- Less commonly affected sites:
  - Pelvis
  - Calcaneus
  - Ribs
  - Ulna
- High-risk stress fractures occur in zones of tension or areas with poor blood supply and are

more likely to result in fracture displacement and/or nonunion. High-risk sites include the following:

- Tension side of femoral neck
  - Anterior tibial diaphysis
  - Sesamoids
  - Pars interarticularis of lumbar spine (L4, L5)
  - 5th metatarsal at metaphyseal-diaphyseal junction
  - Proximal 2nd metatarsal
  - Medial malleolus
  - Tarsal navicular
  - Patella
  - Talar neck
- Synonym(s): march fracture; fatigue fracture

## *EPIDEMIOLOGY*

### *Incidence*

- Greatest incidence in 15- to 27-year-olds
- Females more commonly affected than males
- Affects 9-21% of track and field athletes annually
- Accounts for as many as 8% of visits to sports medicine and orthopedic clinics
- Occurs in <1% of general population

### *Prevalence*

- Affects 5% of military recruits
- Affects 1-3% of college athletes

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Bone is a dynamic tissue that is constantly remodeling in response to applied physiologic stress.
- Repetitive loading or overuse causes microfractures that can't heal due to imbalance between bone resorption and bone formation.

- If microdamage accumulates in excess of reparation, bony fatigue leads to stress fracture.

## *RISK FACTORS*

- Intrinsic
  - Female athlete triad (low energy availability with or without disordered eating, menstrual dysfunction, and low bone mineral density)
  - History of previous stress fracture
  - History of osteoporosis, osteomalacia, rheumatoid arthritis, corticosteroid therapy
  - Skeletal malalignment: pes cavus, pes planus, leg length discrepancies, excessive forefoot varus, tarsal coalitions, prominent posterior calcaneal process, tight heel cords
  - Increased vertical loading rate (e.g., heel-to-toe running instead of forefoot striking)
  - Muscle fatigue and decreased lean muscle mass
  - Extremes of body size and composition
  - Previous inactivity or low aerobic fitness
- Extrinsic
  - Type of exercise—running, track and field, basketball, gymnastics, soccer, and dance are highest risk.
  - Rapid increase in mileage, running pace, or training volume
  - Inappropriate footwear
  - Hard training surface
  - Inadequate recovery or rest and training with fatigued muscle
- Tobacco use

## *GENERAL PREVENTION*

- Avoid abrupt increases in physical activity (no more than 10% increase in load per week).
- Reduce intensity and duration of activity if new onset pain.
- Proper footwear
- Increasing dynamic physical activity (jumping; plyometric training) increases bone density and resistance to mechanical stress.
- Decrease vertical loading rate either by switching to forefoot strike running or (if continuing

with heel-to-toe strike) by using a heel pad insert.

- Shock-absorbing foot inserts may help.
- Increasing calcium and vitamin D intake may reduce stress fracture rates in female runners and military recruits.

## **COMMONLY ASSOCIATED CONDITIONS**

- Osteoporosis/osteopenia
- Female athlete triad
- Metabolic bone disorders

## **DIAGNOSIS**

### **HISTORY**

- Insidious onset of vague bony pain over period of weeks worsened with physical activity
- Rest initially relieves pain.
- If untreated, pain progresses and may occur earlier during training sessions or even at rest. Pain also becomes more localized.
- History of recent change in training intensity, alteration in training terrain, and/or footwear
- Assess dietary practices: energy availability, disordered eating, and weight fluctuations, calcium and vitamin D intake
- Assess menstrual history: menarche, oligomenorrhea, or amenorrhea

### **PHYSICAL EXAM**

- Height, weight, BMI, and any stigmata of disordered eating (cold extremities, hypercarotenemia, lanugo hair, calluses on back of fingers, poor oral hygiene, parotid gland hypertrophy, bradycardia, or orthostatic hypotension)
- Antalgic gait
- Point tenderness or percussion tenderness over injury site
- Placing a vibrating tuning fork over the fracture site may intensify pain.
- Swelling may be present.
- Specific tests:

- Hop test for tibial stress fracture: cannot hop on one leg 10 times; if able to perform test, consider shin splints (medial tibial stress syndrome).
  - Fulcrum test for femoral stress fracture: With patient seated, provoke pain by applying downward force on the distal femur while other hand uses the mid thigh as fulcrum on femoral shaft (use with caution to avoid completing a femoral neck stress fracture if clinical suspicion is high).
  - Single-leg hyperextension (Stork) test for pars interarticularis fracture of lumbar spine: Stand on leg of symptomatic side and extend lumbar spine. Positive if painful.
- Anatomic malalignment may be present (leg length discrepancy, pes planus/cavus).

## *DIFFERENTIAL DIAGNOSIS*

- Shin splints (medial tibial stress syndrome) (pain resolves with rest; stress fracture pain does not)
- Infection (osteomyelitis)
- Soft tissue injury (sprain, tendonitis, and periostitis)
- Compartment syndrome
- Bony fracture
- Neoplasm (osteoid osteoma)
- Entrapment syndromes
- Intermittent claudication

## *DIAGNOSTIC TESTS & INTERPRETATION*

- None unless clinically indicated for suspected disease (e.g., female athlete triad, hyperparathyroidism, and vitamin D deficiency)
- Plain films:
  - First line in suspected stress fracture
  - Findings typically seen 2 to 8 weeks after onset of pain.
  - Sensitivity during early stages (1 to 2 weeks) may be as low as 10%.
  - May see periosteal callus, "gray cortex sign" (region of decreased cortical intensity), osteopenia, endosteal reaction, or ill-defined cortical margin
  - Severe cases may show discrete fracture.

## Follow-Up Tests & Special Considerations

- MRI:
  - Gold standard for imaging stress fractures
  - Very sensitive
  - Better evaluation of exact anatomic location and extent of injury
- Bone scan:
  - Sensitive but nonspecific for stress fracture
  - Should not be used to assess healing process

---

P.991

- CT scan:
  - Less sensitive than MRI or bone scan for early stress fractures but has an important role in evaluating occult fractures of foot, tibia, carpal scaphoid, and pars interarticularis
  - Can distinguish diseases (osteoid osteoma, malignancy, and osteomyelitis) that mimic stress fracture on bone scan
  - Bony detail provided by CT scan allows differentiation of complete versus incomplete fracture, especially when MRI is equivocal.
- US:
  - Not routinely used but may be of particular help in the evaluation of metatarsal stress fracture to distinguish from other causes of metatarsalgia (e.g., Morton neuroma)
- Classification by radiographic grading (1)
- Grade I: normal x-ray, positive short time inversion recovery (STIR) MRI
- Grade II: normal x-ray, positive STIR + positive T2-weighted MRI
- Grade III: discrete line or discrete periosteal reaction on x-ray, positive T1/T2-weighted MRI but with no definite cortical break
- Grade IV: fracture or periosteal reaction on x-ray, positive T1/T2-weighted fracture line.

## TREATMENT

- Protection, rest, ice, compression, and elevation (PRICE) for acute pain and edema
- Decrease activity to the level of pain-free functioning.

- Pain at rest or with gentle range of motion (ROM) may require temporary immobilization.
- Painful ambulation requires patients use crutches with periodic walking trial to assess readiness for nonaided ambulation.
- Pneumatic leg brace is effective in decreasing the return-to-play time for tibial shaft stress fracture (2)[C].
- For low-risk stress fracture, slowly increase impact loading once ambulation and daily activities are pain free. Progression of activity depends on the individual and should be modified according to symptoms (3,4).
- High-risk fractures often require immediate immobilization and a period of non-weight-bearing. Many patients will require early surgical intervention to avoid nonunion and facilitate earlier return to sport (5,6).
- In bisphosphonate-associated femoral stress fracture, prophylactic nail fixation may avoid fracture completion, shorten hospital stay, and decrease subsequent morbidity (7)[C].

## *MEDICATION*

### *First Line*

- Calcium and vitamin D supplementation should be initiated when dietary intake is inadequate or deficiencies are found.
- Acetaminophen
- NSAIDs are beneficial for pain and inflammation but may adversely affect fracture healing and should, therefore, be used only sparingly.
- Bisphosphonates theoretically could treat stress fractures by suppressing bone remodeling. There is no conclusive evidence to prove that this improves fracture healing in humans. Currently, only case reports have shown benefit (8)[A].

## *ISSUES FOR REFERRAL*

Orthopedic consultation for high-risk fractures, failure to improve with standard treatment, evidence of nonunion within 3 to 4 weeks, or inability to tolerate rehabilitation

## *ADDITIONAL THERAPIES*

- Electrical stimulation may be an adjunct for delayed union and nonunion.
- Extracorporeal shock wave therapy (ESWT) and pulsed US may have some potential benefits but require additional study (9)[A].
- Physical therapy:

- Correct training errors and inappropriate mechanics predisposing to stress fracture.
- Strengthen muscles around the site of stress fracture.
- Encourage cross-training to maintain fitness.
- Correct anatomic variations.
- Antigravity treadmills

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Once the patient is pain free, low-impact training can start and be advanced gently as tolerated.
- Once running has resumed, increase mileage slowly.

### *Patient Monitoring*

Radiographs every 4 to 6 weeks to document healing progress

### *PATIENT EDUCATION*

- Gradually increase activity as long as pain free
- Rest and reevaluate if there is a recurrence of pain.
- Correct mechanical and training errors.
- Strengthen core muscles.

### *PROGNOSIS*

- Stress fractures in young people have a good prognosis.
- Older patients or those with metabolic bone disease often develop insufficiency fractures in other bones.
- Time to return to full activity:
  - Grade I: 3+ weeks
  - Grade II: 5+ weeks
  - Grade III: 11+ weeks
  - Grade IV: 14+ weeks

## COMPLICATIONS

- Completion of fracture
- Delayed union
- Nonunion
- May require surgery with internal fixation

### ICD10

- M84.38XA Stress fracture, other site, initial encounter for fracture
- M84.369A Stress fracture, unsp tibia and fibula, init for fx
- M84.376A Stress fracture, unspecified foot, init encntr for fracture

## Clinical Pearls

&NA;

- The diagnosis of stress fractures requires a high index of suspicion. X-rays are often negative initially.
- Identify and treat female athletic triad to prevent stress fractures.
- Progress activity levels gradually and avoid sudden increases in activity or running mileage to help prevent stress fractures.
- High-risk fractures often require immobilization and surgery.

# Stroke Rehabilitation

Aaron Hauptman, MD

Jordan Eisenstock, MD

Robert A. Baldor, MD, FAAFP

## BASICS

### DESCRIPTION

- Stroke is a compromise in blood supply to an area of the nervous system, secondary to hemorrhage or occlusion, with resultant infarction of nervous tissue.
- 3rd leading cause of death and the leading cause of long-term disability in the United States (1)
- Rehabilitation refers to the process of restoring a debilitated person toward baseline functionality.
- Specific rehabilitation techniques should be used depending on the individual and based on particular deficits and brain regions impacted.
- Rehabilitation involves cycling through the following (2):
  - Assessment of patient with the goal of identification and quantification needs of the individual
  - Setting of objectives that are realistic, concrete, and attainable
  - Repetition of assessment to gauge changes in status, with subsequent alteration of techniques as necessary
- Motor impairment is the most commonly recognized impairment secondary to stroke.
- Speech and language, swallowing, vision, sensation, and cognition are also commonly impaired.

### EPIDEMIOLOGY

#### Incidence

- Each year, ÷795,000 people suffer stroke; ÷610,000 are first attacks, and 185,000 are recurrent attacks (3).

- ÷14% of stroke survivors reach full recovery in physical function; 25-50% need assistance poststroke (1).
- According to the WHO, 15 million people suffer stroke worldwide each year. Of these, 5 million die and another 5 million are permanently disabled.

## *Prevalence*

- ÷7 million Americans <sup>3</sup>20 years old have had a stroke (÷3%) (3).
- ÷50 million stroke survivors worldwide (4)
- >1/2 of strokes in people <65 years result in death within 8 years (1).

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Stroke involves a compromise in blood supply to an area, usually by either rupture or blockage of a vessel. Of all strokes, 87% are ischemic, 10% intracerebral hemorrhage, and 3% subarachnoid hemorrhage (3).

### *Neural Mechanisms of Remodeling*

Poststroke remodeling changes provide some degree of recovery that varies considerably between individuals. Outcomes are greatest when remodeling mimics normal organization to the greatest degree possible. Neurophysiologic changes involved in spontaneous recovery include the following (5)[B]:

- Augmented excitability in areas of cortex functionally connected to injured brain
- Increased activity contralateral to traumatized cortex
- Changes in somatotopic map in other regions

Research suggests a critical window for neurophysiologic changes, further understanding of which may facilitate neurorehabilitation by augmenting endogenous healing. Animal studies suggest promising strategies for enhancing rehabilitative efforts including growth factors, hormones, proteins, cytokines, stem cells, and so forth. Studies are ongoing exploring combinations of plasticity-promoting factors, rehabilitative training, and imaging/biomarker modalities together with carefully timed neurorehabilitation that takes advantage of endogenous plasticity timing. Such work is complicated by the vast heterogeneity of stroke insults but offers promising options for future multimodal treatments.

## *RISK FACTORS*

Risk factors for stroke are discussed in the topics ÒStroke, AcuteÓ and ÒAtherosclerosis.Ó

# GENERAL PREVENTION

See ÒStroke, Acute.Ó

## DIAGNOSIS

### HISTORY

- For acute stroke symptoms, see "Stroke, Acute."
- A wide variety of systems and functions are commonly impacted by stroke, depending on type, severity, location, and so forth including the following (2):
  - Consciousness and psychological functions
    - Orientation, arousal, alertness, attention, intellect, personality, sleep, memory, cognition, perception, behavior, temperament, psychomotor functions, and so forth
  - Perceptual functions, most commonly
    - Vision, proprioception, touch sensation
  - Communication, excretory, and sexual functions
    - Vocal control and articulation; intake of food (chewing, swallowing), urinary and bowel functions; sexual function
  - Neuromuscular and ADLs
    - Muscle strength, stability, endurance, reflexes, tone, gait, voluntary movement

### PHYSICAL EXAM

- Neurologic manifestations should be examined based on location of stroke when known but should include investigation of the following:
  - Sensory or motor deficits, especially unilaterally (i.e., hemiparesis/hemiplegia)
  - Dysarthria or aphasia
  - Visual field deficits (i.e., hemianopsia)
  - Dysphagia
  - Apraxia
  - Unilateral facial palsy
- Neuropsychiatric evaluation should be undertaken to assess cognitive, intellectual, personality,

memory, psychomotor, and other system changes that may benefit from treatment during rehabilitation.

## ***DIFFERENTIAL DIAGNOSIS***

- Differential diagnosis in stroke rehabilitation should take into account acute changes that are inconsistent with general trend in the individual patient's status.
- New changes in motor function, mental status, and so forth could represent new stroke.
- Subacute changes could include a wide range of neuromuscular, neuropsychiatric, or psychiatric diseases that could be related or unrelated to the initial stroke event.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

A wide range of standardized, quantifiable scales have been used to track outcomes in stroke rehabilitation. These include the following (2):

- Neurologic scales
  - Glasgow Coma scale, Mini-Mental State Examination, NIH stroke scale among others
- Global ADL scales
  - Including, but not limited to, Barthel index, functional independence measure, modified Rankine scale, Frenchay activities index, Trunk Control Test, timed up-and-go test, Stair Climb Test, Toronto Bedside Swallowing Screening Test, and so forth.
- Family and caretaker contextual factors are very important to stroke rehabilitation and have been shown to impact outcomes, so thorough assessment should include testing such as the following:
  - Caregiver Strain Index, Family Assessment Device

See topic "Stroke, Acute."

## **Follow-Up Tests & Special Considerations**

Monitor the coagulation profile of patients on anticoagulants.

## **TREATMENT**

- Tailor to specific stroke-related sequelae.
- The three major stroke rehabilitation goals are as follows (1):
  - Prevent/treat prolonged inactivity complications.

- Prevent recurrent stroke and cardiovascular events.
- Increase aerobic fitness.

## GENERAL MEASURES

Prevention and/or treatment of the complications associated with stroke (4)[C]

- Aspiration
  - Immediately after stroke, up to 50% of patients have dysphagia; this improves in many.
  - Remain NPO until bedside swallow assessment.
  - Prevention of aspiration involves postural changes, increased sensory input, swallowing maneuvers, active exercise programs, diet modifications, nonoral feeding (if indicated), psychological support, and supportive nursing
- Pulmonary embolism/deep venous thrombosis
  - Risk is highest during the first 3 to 120 days poststroke.
  - Pneumatic compression devices and compression stockings
  - Ambulation as soon as possible
- Skin breakdown
  - Increased risk due to loss of sensation, impaired circulation, older age, decreased level of consciousness, inability to move due to paralysis, and incontinence of urine or stool
  - Frequent repositioning (at least q2h) with special care to avoid excessive friction
  - Keep skin clean and dry.
- Spasticity
  - Occurs in ÷35% of stroke survivors; treat with combination of modalities:
    - Range-of-motion exercises
    - Heat, cold, or electric stimulation
    - Splinting
    - Oral medications for spasticity of cerebral origin (e.g., dantrolene, tizanidine); phenol or botulinum toxin injections for targeting specific muscles or muscle groups
- Malnutrition
  - Nutritional assessment with a diet history and monitoring by a dietician

- Seizures
  - More common after hemorrhagic stroke (11%) than after ischemic stroke (9%)
  - Antiepileptic drugs and elimination of disturbances (i.e., toxins, metabolic) that may lower seizure threshold

---

P.993

- Falls
  - Lifestyle changes
    - Avoid loose rugs; maintain a clear path without obstruction.
    - Avoid slippery surfaces (such as wet floors).
    - Maintain good lighting.
    - Shoes with nonskid soles
    - Slow down movements for transfers or walking.
- Severe sleep apnea
  - Lifestyle changes
    - Stop smoking; lose weight.
    - Sleep on side versus back.
    - Mouthpieces and breathing devices (CPAP)
    - Surgery
- Neurocognitive (6)
  - Wide range of deficit patterns that can be focal (e.g., aphasia) or diffuse (general cognitive slowing)
    - Most broadly effected are orientation, language, attention, and memory.
    - Common particular deficits: aphasia, neglect, cognitive slowing, memory/executive deficits
    - Assessment, treatment, and outcomes vary markedly based on stroke type, location, severity, timing, and additional factors.
    - Cognitive rehabilitation has some success in focal deficits but less in diffuse changes.
    - Pharmacology: evidence of efficacy for escitalopram and rivastigmine

- Additional modalities under investigation: Therapies such as repetitive transcranial magnetic stimulation and prism adaptation have shown some benefit in driving plasticity and functional brain changes.
- Depression
  - May be organic secondary to stroke or reactive to the stroke itself
  - Poststroke depression has been found to cause higher mortality, poorer functional recovery, and less activity socially (1)[C].
  - Treat with a combination of pharmacotherapy and psychotherapy:
    - Evidence suggests heterocyclic antidepressants are effective in the setting of poststroke depression but must be closely monitored in older adults due to side effects.
    - SSRIs are also effective in treating poststroke depression.
    - All stroke patients should be assessed for depression and treated with the appropriate antidepressant for 6 months.

## **MEDICATION**

### ***First Line***

- Management of controllable risk factors, including BP reduction, diabetes, and cholesterol (Initiate statin therapy, if history of TIA or stroke with evidence of atherosclerosis, LDL  $\geq$ 100, and no CHD.)
- Anticoagulation with warfarin for patients with mechanical prosthetic heart valves and ischemic stroke or TIA (dosage varies depending on optimum INR for patient in setting of comorbidities)
- Note potential medication interactions (e.g., warfarin and SSRIs due to liver enzyme metabolism).
- Antiplatelet drugs (aspirin, aspirin/dipyridamole, clopidogrel) decrease relative risk of stroke, MI, or death by  $\approx$ 22% (7)[C].

## **ISSUES FOR REFERRAL**

For stroke survivors who require 24-hour care of medical comorbidities, close physician supervision, and specialized nursing care (RN with specialized training or rehabilitation experience), an inpatient rehabilitation facility (IRF) can offer hospital-level care.

## **ADDITIONAL THERAPIES**

Physical, occupational, speech, and recreational therapy

# INPATIENT CONSIDERATIONS

## *Admission Criteria/Initial Stabilization*

- For stroke survivors requiring 24-hour care, close physician supervision, and specialized nursing care (RN with specialized training or rehabilitation experience), an inpatient rehabilitation facility (IRF) can offer hospital-level care.
- Such patients must also require and receive a minimum of 3 hours daily occupational or physical therapy for no <5 days each week; this can be combined with other skilled modalities, such as speech-language or prosthetic-orthotic services) to meet the 3-hr/day requirement.
- Either the aforementioned is required or an IRF is the only reasonable setting in which a low-intensity rehab program may be executed.
- An alternative setting is a skilled nursing facility for residents needing daily rehabilitation or nursing care on an inpatient basis.

See "Stroke, Acute."

## *IV Fluids*

Avoid D5W in acute setting to avoid hyperglycemia and its secondary effects.

## *Nursing*

An alternative inpatient setting is a skilled nursing facility that provides nursing care or rehabilitation to residents needing daily rehabilitation or nursing care on an inpatient basis.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

Patient should follow-up regularly with primary care physician for management of risk factors for stroke.

## *Patient Monitoring*

Continue to monitor risk factors. Lab studies monitored periodically may include hemoglobin A1c (and finger-stick glucose testing in diabetics), lipid panel, CBC including platelets, lipid profile, coagulation studies (PT/INR) of special importance in patients on anticoagulation).

## *DIET*

Low salt, low calorie, low saturated and trans fat, low cholesterol

# PATIENT EDUCATION

National Stroke Association: <http://www.stroke.org/>

## PROGNOSIS

- Strong evidence suggests an organized, interdisciplinary stroke care team of physicians, nurses, therapists, family, and patient can reduce mortality rates and the likelihood of institutional care and long-term disability. It can also enhance recovery and increase ADL independence.
- Aggressive rehabilitation beyond the time window of the 1st poststroke months, including treadmill with or without body weight support, can increase aerobic capacity and sensorimotor functionality.

## COMPLICATIONS

- Aspiration
- Pulmonary embolism/deep venous thrombosis
- Muscle atrophy
- Osteoporosis
- Skin breakdown
- Spasticity
- Malnutrition
- Seizures
- Severe sleep apnea

- Traumatic Brain Injury (TBI) – Long Term Care; Stroke, Acute; Dementia; Delirium
- Algorithm: Stroke

## Codes

&NA;

### ICD10

- I63.9 Cerebral infarction, unspecified
- I69.10 Unsp sequelae of nontraumatic intracerebral hemorrhage
- I69.11 Cognitive deficits following nontraumatic intracerebral hemorrhage

## Clinical Pearls

&NA;

- Stroke is the third leading cause of death and the leading cause of long-term disability in the United States.

- An essential part of poststroke management is the treatment of controllable risk factors, including BP reduction and cholesterol control (initiate statin therapy, if history of TIA or stroke with evidence of atherosclerosis, LDL  $\geq$  100).
- Strong evidence suggests an organized, interdisciplinary stroke care team of physicians, nurses, therapists, family, and patient can reduce mortality rates and the likelihood of institutional care and long-term disability. It can also enhance recovery and increase ADL independence.

# Stroke, Acute

Scott A. Drummond Jr., DO, DABR

## BASICS

A cerebrovascular accident (CVA) is an infarction or hemorrhage in the brain.

### DESCRIPTION

Stroke is the sudden onset of a focal neurologic deficit(s) resulting from either infarction or hemorrhage within the brain.

- Two broad categories: ischemic (thrombotic or embolic; 87%) and hemorrhagic (13%)
- Hemorrhage can be intracerebral or subarachnoid.
- System(s) affected: neurologic; vascular
- Synonym(s): CVA; cerebral infarct; brain attack
- Related terms: transient ischemic attack (TIA), a transient episode of neurologic dysfunction due to focal ischemia without permanent infarction on imaging (see topic *Transient Ischemic Attack [TIA]*)

### Pediatric Considerations

- Cardiac abnormalities (congenital heart disease, paradoxical embolism, rheumatic fever, bacterial endocarditis)
- Metabolic: homocystinuria, Fabry disease

### EPIDEMIOLOGY

#### Incidence

Annual incidence in the United States is  $\div$  795,000.

#### Prevalence

- Prevalence in the United States: 550/100,000
- Predominant age: Risk increases >45 years of age and is highest during the 7th and 8th decades.

- Predominant sex: male > female at younger age, but higher incidence in women with age > 75 years

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- 87% of stroke is ischemic, three main subtypes for etiology: thrombosis, embolism, and systemic hypoperfusion. Large vessel atherothrombotic strokes are commonly related to the origin of the internal carotid artery. Small vessel lacunar strokes are commonly due to lipohyalinotic occlusion. Embolic strokes are largely from a cardiac source (due to left atrial thrombus, atrial fibrillation, recent MI, valve disease, or mechanical valves) or ascending aortic atheromatous disease (>4 mm).
- 13% of stroke is hemorrhagic; most commonly due to HTN. Other causes include intracranial vascular malformations (cavernous angiomas, AVMs), cerebral amyloid angiopathy (lobar hemorrhages in elderly), and anticoagulation.
- Other causes include fibromuscular dysplasia (rare), vasculitis, or drug use (cocaine, amphetamines).

## **Genetics**

Stroke is a polygenic multifactorial disease, with some clustering within families.

## **RISK FACTORS**

- Uncontrollable: age, gender, race, family history/genetics, prior stroke or TIA
- Controllable/modifiable/treatable
  - Metabolic: diabetes, dyslipidemia
  - Lifestyle: smoking, cocaine use, amphetamine use
  - Cardiovascular: hypertension, atrial fibrillation, valvular heart disease, endocarditis, recent MI, severe carotid artery stenosis, hypercoagulable states, and patent foramen ovale

## **GENERAL PREVENTION**

Smoking cessation, regular exercise, weight control to maintain nonobese BMI and prevent type 2 diabetes, use alcohol in moderation, control BP, and manage hyperlipidemia; use of antiplatelet agent, such as aspirin, in high-risk persons; treatment of nonvalvular atrial fibrillation with dose-adjusted warfarin or dabigatran, apixaban, and rivaroxaban

## **COMMONLY ASSOCIATED CONDITIONS**

Coronary artery disease is the major cause of death during the first 5 years after a stroke.

# DIAGNOSIS

## HISTORY

Acute onset of focal arm/leg weakness, facial weakness, difficulty with speech or swallowing, vertigo, visual disturbances, diminished consciousness; presence of vomiting and severe headache favor diagnosis of hemorrhagic stroke.

## PHYSICAL EXAM

- Assess airway, breathing, and circulation (ABC).
- Anterior (carotid) circulation: hemiparesis/hemiplegia, neglect, aphasia, visual field defects
- Posterior (vertebrobasilar) circulation: diplopia, vertigo, gait and limb ataxia, facial paresis, Horner syndrome, dysphagia, dysarthria, alternating sensory loss

## DIFFERENTIAL DIAGNOSIS

- Migraine (complicated)
- Postictal state (Todd paralysis)
- Systemic infection, including meningitis or encephalitis (infection also may uncover or enhance previous deficits)
- Toxic or metabolic disturbance (hypoglycemia, acute renal failure, liver failure, drug intoxication)
- Brain tumor, primary or metastases
- Head trauma, encephalopathy
- Other types of intracranial hemorrhage (epidural, subdural, subarachnoid)
- Trauma, septic emboli

## DIAGNOSTIC TESTS & INTERPRETATION

Primarily used to narrow differential and identify etiology of stroke

### *Initial Tests (lab, imaging)*

- Serum glucose level, including fingerstick testing (REQUIRED to exclude hypo- and hyperglycemia) (1)[B]
- ECG
- CBC, including platelets

- Electrolytes, including BUN and creatinine
- Coagulation studies: PT, PTT, INR
- Markers of cardiac ischemia
- Emergent brain imaging with noncontrast CT (or brain MRI with diffusion weighted [DW-MRI]) to exclude hemorrhage can be lifesaving (1)[A].
- Subsequent multimodal CT (perfusion CT, CTA, unenhanced CT) or MRI to improve diagnosis of acute ischemic stroke

## *Follow-Up Tests & Special Considerations*

Consider LFT, tox screen, blood alcohol, ABG, lumbar puncture if suspected subarachnoid hemorrhage (SAH), EEG if suspect seizures, blood type and cross.

- DW-MRI is more sensitive than CT for acute ischemic stroke; however, MRI also is better than CT for diagnosis of posterior fossa lesions (2)[B].
- Emergent treatment (IV thrombolysis) should NOT be delayed to obtain advanced imaging studies.
- Follow-up imaging of carotid vessels with Doppler ultrasound, CTA, or MRA of head and neck should be completed.

## *Diagnostic Procedures/Other*

Echocardiogram (transthoracic and/or transesophageal) in patients with increased suspicion for cardioembolic source. In cryptogenic stroke patients, prolonged ECG monitoring should be performed with a 30-day event monitor.

## *Test Interpretation*

Early CT findings: hyperdense MCA sign (increased attenuation of proximal portion of the MCA; is associated with thrombosis of MCA), loss of graywhite matter differentiation, sulcal effacement, loss of insular ribbon

## **TREATMENT**

- BP closely monitored in the first 24 hours (1)[A]
  - Antihypertensives should be withheld unless systolic BP >220 mm Hg or diastolic BP >120 mm Hg, with a goal to lower BP by  $\div$ 15% during first 24 hours if treatment is indicated. If thrombolytic therapy is to be initiated, BP must be <185/110 mm Hg prior to thrombolytics.

- In acute spontaneous intracranial hemorrhagic stroke, goal for BP control is 160/90 mm Hg or target MAP 110 (see topic, "Subarachnoid Hemorrhage" for details on BP management). With suspicion for elevated ICP, BP should be reduced with goal to keep cerebral perfusion pressure between 61 mm Hg and 80 mm Hg.
- Antihypertensive medications should be restarted 24 hours after stroke onset for patients with a history of hypertension who are neurologically stable.

## **ALERT**

Thrombolysis: IV thrombolysis should be started in patients with measurable neurologic deficits that do not clear spontaneously, presenting within 3 to 4.5 hours of stroke symptom onset.

- Exclusion criteria for thrombolysis within 3 hours of onset include:
  - Symptoms suggestive of SAH
  - Head trauma or prior stroke within 3 months
  - MI within 3 months
  - GI or gastric ulcer hemorrhage within 21 days
  - Major surgery within 14 days
  - Arterial puncture at noncompressible site within 7 days
  - Any history of intracranial hemorrhage
  - Elevated BP (systolic >185 mm Hg and diastolic >110 mm Hg)
  - Active bleeding or acute trauma on examination
  - Taking anticoagulant and INR  $\geq 1.7$
  - Activated PTT not in normal range if heparin received during previous 48 hours; platelet count <100,000 mm<sup>3</sup>
  - Blood glucose concentration <50 mg/dL
  - Seizure with postictal residual neurologic impairment
  - Multilobar infarction on CT (hypodensity >1/3 cerebral hemisphere)
  - Patient or family members not able to weigh and understand potential risks and benefits of treatment

- Extended exclusion criteria for thrombolysis within 4.5 hours include per AHA/ASA guidelines:

Age >80 years

- All patients taking oral anticoagulants regardless of INR
  - National Institute of Health (NIH) Stroke Scale >25
  - History of stroke and diabetes
- Antiplatelet agents: Oral aspirin (initial dose, 325 mg) should be started within 24 to 48 hours (1)[A].

## MEDICATION

### *First Line*

- BP management (parameters under "Treatment") options include:
  - Labetalol 10 to 20 mg IV over 1 to 2 minutes, which may be repeated once
  - Nicardipine infusion 5 mg/hr, titrate up by 2.5 mg/hr at 5- to 15-minute intervals to maximum of 15 mg/hr; reduce to 3 mg/hr when target BP is reached
- Thrombolysis, IV administration of rtPA: Infuse 0.9 mg/kg, maximum dose 90 mg over 60 minutes with 10% of dose given as bolus over 1 minute.
  - Admit to ICU or stroke unit, with neurologic exams every 15 minutes during infusion, every 60 minutes for next 6 hours, then hourly until 24 hours after treatment.
  - Discontinue infusion and obtain emergent CT scan if severe headache, angioedema, acute hypertension, or nausea and vomiting develop.
  - Measure BP every 15 minutes for first 2 hours, every 30 minutes for next 6 hours, then every hour until 24 hours after treatment. Maintain BP < 185/105. Follow-up CT at 24 hours before starting anticoagulants or antiplatelet agents.
- Antiplatelet: aspirin 325 mg/day within 48 hours, or 24 to 48 hours after thrombolytic therapy (1)[A]

### *Second Line*

Carotid endarterectomy (CEA) for carotid artery stenosis rarely is indicated emergently. CEA is indicated for stenosis >70% ipsilateral to TIA or incomplete stroke lesion and may be indicated for 50-69% stenosis in carefully selected patients, depending on risk factors.

## ISSUES FOR REFERRAL

Follow-up with neurologist 1 week after discharge, with subsequent follow-up based on individual circumstances

## ***ADDITIONAL THERAPIES***

- Prophylactic antibiotics are *not* recommended.
- Deep vein thrombosis (DVT) prophylaxis should be instituted for immobilized patients.
- Corticosteroids are *not* recommended for cerebral brain edema.
- Statin use should be continued without interruption following acute stroke (1)[B].
- At discharge, patient should be referred for physical therapy, occupational therapy, and speech therapy, as necessary.

## ***SURGERY/OTHER PROCEDURES***

- Ventricular drain may be placed for patients with acute hydrocephalus secondary to stroke (most commonly due to cerebellar stroke).
- Decompressive surgery is recommended for major cerebellar infarction; it should be considered for malignant middle cerebral artery infarction, especially if the patient is <60 years of age.
- Consider mechanical embolus removal with a cerebral infarction device in carefully selected patients, with evidence of potentially salvageable tissue on advanced imaging.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Acupuncture starting within 30 days from stroke onset may improve neurologic functioning.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Observe closely within first 24 hours for neurologic decline, particularly due to cerebral edema.
- Keep head of bed at least 30 degrees when elevated ICP is suspected. Patients with ischemic stroke may benefit from a horizontal bed position during the acute phase.
- Monitor cardiac rhythm for at least first 24 hours to identify any arrhythmias.
- Airway support and ventilatory assistance may be necessary due to diminished consciousness or bulbar involvement; supplemental oxygen should be reserved for hypoxic patients. Consider elective intubation for patients with malignant edema.
- Correct hypovolemia with normal saline.
- All patients should be kept NPO until a formal swallow evaluation has been performed; to reduce risk of aspiration pneumonia, maintain elevated head of bed to 30 degrees.

- Hypoglycemia can cause neurologic dysfunction; rapidly correct during initial evaluation.
- Hyperglycemia within first 24 hours after stroke is associated with poor functional outcomes and AHA/ASA guidelines: insulin treatment for patients with glucose levels >140 to 180 mg/dL (1)[C].
- In patients with ICH secondary to anticoagulant use, correction of an elevated INR is necessary with use of IV vitamin K and fresh frozen plasma or prothrombin concentrate complex. Factor VII infusion should be used in patients needing urgent surgical intervention (i.e., those with cerebellar hemorrhage who are neurologically deteriorating).
- DVT prophylaxis (1)[B]
- Maintain oxygen saturation >94% (1)[C].
- Early use of physical therapy and discharge planning for rehabilitation need and placement

### *IV Fluids*

IV hydration with maintenance amounts of normal saline until swallowing status is assessed; monitor fluid balance closely.

### *Nursing*

- Regular neurologic exams more frequent in first 24 hours (every 1 to 2 hours)
- Fall precautions; frequent repositioning to prevent skin breakdown

### *Discharge Criteria*

Medically stable, adequate nutritional support, neurologic status stable or improving

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Secondary prevention of stroke with aggressive management of risk factors
- Platelet inhibition using aspirin, clopidogrel, or aspirin plus extended-release dipyridamole (Aggrenox) based on physician and patient preference

### *Patient Monitoring*

Follow-up every 3 months for 1st year, then annually.

### *DIET*

Patients with impaired swallowing should receive nasogastric or percutaneous endoscopic gastrostomy feedings to maintain nutrition and hydration.

## **PATIENT EDUCATION**

National Stroke Association (800-STROKES or <http://www.stroke.org>)

## **PROGNOSIS**

Variable, depends on subtype and severity of stroke; NIH stroke scale may be used for prognosis.

## **COMPLICATIONS**

- Acute: brain herniation, hemorrhagic transformation, MI, congestive heart failure, dysphagia, aspiration pneumonia, UTI, DVT, pulmonary embolism, malnutrition, pressure sores
- Chronic: falls, depression, dementia, orthopedic complications, contractures

## **REFERENCES**

1. Jauch EC, Saver JL, Adams HP Jr, et al. Guidelines for the early management of patients with acute ischemic stroke: a guideline for healthcare professionals from the American Heart Association/American Stroke Association. *Stroke*. 2013;44(3): 870-947.

2. Chalela JA, Kidwell CS, Nentwich LM, et al. Magnetic resonance imaging and computed tomography in emergency assessment of patients with suspected acute stroke: a prospective comparison. *Lancet*. 2007;369(9558):293-298.

## **Additional Reading**

&NA;

Yew KS, Cheng EM. Diagnosis of acute stroke. *Am Fam Physician*. 2015;91(8):528-536.

## **Codes**

&NA;

## **ICD10**

- I63.9 Cerebral infarction, unspecified
- I61.9 Nontraumatic intracerebral hemorrhage, unspecified

- I63.50 Cereb infrc due to unsp occls or stenosis of unsp cereb artery

## Clinical Pearls

### &NA;

- Unless stroke is hemorrhagic or patient is undergoing thrombolysis, BP should not be lowered acutely to maintain perfusion of penumbra region.
- IV thrombolysis should be considered in eligible patients with neurologic deficits that do not clear spontaneously within 3 to 4.5 hours of symptom onset.
- DW-MRI is more sensitive than conventional CT for acute ischemic stroke. MRI is also better than CT for diagnosis of posterior fossa lesions.

# Subconjunctival Hemorrhage

Cara Marshall, MD

## BASICS

### DESCRIPTION

- Subconjunctival hemorrhage (SCH) is bleeding from small blood vessels underneath the conjunctiva, the thin clear skin covering the sclera of the eye.
- SCH is diagnosed clinically:
  - Flat, well-demarcated areas of extravasated blood can be seen just under the surface of the conjunctiva of the eye (red patch of blood sign).
  - SCH is more common in the inferior and temporal regions (1).
- Typically, SCH resolves spontaneously within 1 to 2 weeks.

### EPIDEMIOLOGY

- Male = female; no gender predilection found
- Common; 3% rate of diagnosis in outpatient eye clinic (2)

### Incidence

Incidence increases

- With increasing age
- In contact lens wearers (5% of cases) (3)
- With systemic diseases such as diabetes, hypertension (HTN), and coagulation disorders
- During summer months, possibly due to trauma (2)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Direct trauma to the blood vessels of the conjunctiva from blunt or penetrating trauma
- Direct trauma to the conjunctiva from improper contact lens placement or improper cleaning
- Increased BP in the vessels of the conjunctiva from HTN or from the temporary increase in BP

from a Valsalva type maneuver (e.g., vomiting)

- Damaged vessels from diabetes and atherosclerotic disease
- Increased bleeding tendencies from either thrombocytopenia or elevated PT/elevated INR (4)
- Trauma to the eye
- Valsalva maneuvers causing sudden severe venous congestion such as coughing, sneezing, vomiting, straining, severe asthma or COPD exacerbation, weightlifting or childbirth/labor (1)
- HTN
- Atherosclerotic disease and diabetes
- Bleeding factors such as thrombocytopenia or elevated PT (from either disease or medication side effects)
- In patients age >60 years, HTN is the most common etiology.
- In patients age <40 years, trauma/Valsalva and contact lens use are the most common etiologies.
- In patients age >40 years, conjunctivochalasis (redundant conjunctival folds) and presence of pinguecula are strongly associated (3).

## ***RISK FACTORS***

- Age
- Contact lens wearer
- Systemic diseases
- Bleeding disorders (2)
- Recent cataract surgery

## ***GENERAL PREVENTION***

- Correct cleaning and maintenance of contact lenses.
- Protective eyewear in sports and hobbies
- Control of high BP
- Optimizing control of systemic diseases such as diabetes and atherosclerotic disease
- Control of prothrombin time (PT)/international normalized ratio (INR) in patients on Coumadin therapy (5)

# DIAGNOSIS

## HISTORY

- Generally asymptomatic; usually the patient notices the redness in the mirror or another person mentions it to the patient.
- There should be little to no pain involved (5)[C].
- Obtain history of trauma. SCH can occur 12 to 24 hours after orbital fracture (1).
- Obtain history of contact lens usage or recent cataract, laser-assisted in situ keratomileusis (LASIK), or other ocular surgery (2)[C].
- Comprehensive past medical history to evaluate if at risk for systemic diseases or taking medications that might increase risk
- Obtain history for current systemic symptomatology.

## PHYSICAL EXAM

- Evaluate BP to assess control (2)[C].
- Measure visual acuity; this should be normal in a simple SCH (5)[C].
- Verify that the pupils are equal and reactive to light and accommodation; this should be normal with an SCH (5)[C].
- There should be no discharge or exudate noted (5)[C].
- Look at sclera for a bright red demarcated patch.
  - Demarcated area is most often on inferior aspect of eye due to gravity (3)[C].
- If penetrating trauma is a consideration, do a gentle digital assessment of the integrity of the globe (4)[C].
- Slit-lamp exam should be performed if there is a history of trauma (1).

## Geriatric Considerations

In older adults, the area of SCH will be more widespread across the sclera (3). Elastic and connective tissues are more fragile with age, and underlying conditions such as HTN and diabetes may contribute.

## DIFFERENTIAL DIAGNOSIS

- Viral, bacterial, allergic, or chemical conjunctivitis (enterovirus and coxsackie virus most common) (1)[B]

- Foreign body to conjunctiva
- Penetrating trauma
- Acute angle glaucoma
- Iritis
- Recent ocular surgery
- Contact lens induced
- Child abuse (particularly if bilateral in an infant or toddler) (1)
- May occur in newborns after vaginal delivery

P.997

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Typically no testing is indicated; SCH is a clinical diagnosis. If a foreign body is suspected, perform a fluorescein exam.
- Fluorescein exam of a patient with a SCH should show no uptake of staining (5)[C].
- If an orbital fracture is suspected, may obtain plain facial bone films or CT scan (4)[C]

## **Follow-Up Tests & Special Considerations**

If history and physical exam suggest a bleeding etiology (5)[C]

- CBC
- PT/INR

### **ALERT**

If a penetrating injury is suspected, may obtain a CT scan of the orbits but not an MRI (if object may be metal) (4)[C]

## **TREATMENT**

### *GENERAL MEASURES*

- Control BP.
- Control blood glucose.
- Control INR.

Wear protective eyewear.

## *MEDICATION*

No prescription medications are useful in treatment of SCH.

## *ISSUES FOR REFERRAL*

- If a penetrating eye injury is suspected, send the patient to the emergency room for emergent ophthalmology consultation.
- If the patient complains of any decreased visual acuity or visual disturbances, refer to an ophthalmologist as soon as possible.
- If there is no resolution of SCH within 2 weeks, patient may need referral to an ophthalmologist.

## *ADDITIONAL THERAPIES*

- Warm compresses
- Eye lubricants (5)[C]

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

- Follow up only if the area does not resolve within 2 weeks.
- If SCH recurs, then work up patient for systemic sources such as bleeding disorders (5)[C].

## *PATIENT EDUCATION*

- Reassurance of the self-limited nature of the problem and typical time frame for resolution
- Education to return to clinic if the area does not heal or recurs.
- Correct cleaning and maintenance of contact lenses.
- Instructions on causes, self-care, and warning signs are available at PubMed Health: Subconjunctival Hemorrhage at [www.ncbi.nlm.nih.gov/pubmedhealth/PMH0002583/](http://www.ncbi.nlm.nih.gov/pubmedhealth/PMH0002583/).

## *PROGNOSIS*

Excellent

## **COMPLICATIONS**

## Codes

&NA;

## ICD10

- H11.30 Conjunctival hemorrhage, unspecified eye
- H11.31 Conjunctival hemorrhage, right eye
- H11.32 Conjunctival hemorrhage, left eye

# Clinical Pearls

## **&NA;**

- SCH is a clinical diagnosis. The condition is typically asymptomatic and will resolve spontaneously in 1 to 2 weeks.
- Always check BP in a patient with SCH, as HTN is a risk factor.
- Indications for immediate referral to an ophthalmologist are eye pain, change in vision, lack of pupil reactivity, and/or penetrating eye trauma.
- Reassurance and comfort measures are key.
- Contact lens wearers should not wear contacts until the SCH resolves completely.

# Substance Use Disorders

S. Lindsey Clarke, MD, FAAFP

## BASICS

### DESCRIPTION

A substance use disorder manifests as any pattern of substance use causing significant physical, mental, or social dysfunction.

- Substances of abuse include the following:
  - Alcohol
  - Tobacco
  - Cannabinoids (marijuana)
  - Synthetic cannabinoids (Spice, K2, Mojo, Cloud 9, Relax, Crown); note: Increasingly, these are sold as liquid in eyedropper bottles for use with vaporizing devices (vape/hookah pens).
  - Prescription medications
    - CNS depressants (barbiturates, benzodiazepines, hypnotics)
    - Opioids and morphine derivatives (codeine, fentanyl, hydrocodone, hydromorphone, oxycodone [Opana], meperidine, methadone, morphine, oxycodone)
    - Stimulants (amphetamines, methylphenidate)
    - Dextromethorphan
  - Stimulants (cocaine, amphetamines, methamphetamines, Khat)
  - Club drugs (MDMA [ecstasy, Molly], PMMA [Superman], flunitrazepam, &agr;-hydroxybutyrate [GHB])
  - Opioids (heroin, opium, desomorphine [Krokodil])
  - Dissociative drugs (ketamine, phencyclidine [PCP])
  - Hallucinogens (lysergic acid diethylamide [LSD], salvia)
  - Synthetic cathinones (bath salts, Flakka/&agr;-PVP)
  - Inhalants (glue, paint thinners, nitrous oxide)

- Anabolic steroids
- See also [www.drugabuse.gov/drugs-abuse](http://www.drugabuse.gov/drugs-abuse).
- System(s) affected: cardiovascular, endocrine/metabolic, CNS
- Synonym(s): drug abuse; drug dependence; substance abuse

### *Geriatric Considerations*

- Alcohol is the most commonly abused substance, and abuse often goes unrecognized.
- Higher potential for drug interactions

### *Pregnancy Considerations*

Substance abuse may cause fetal abnormalities, morbidity, and fetal or maternal death.

## **EPIDEMIOLOGY**

### *Incidence*

- Predominant age: 16 to 25 years
- Predominant sex: male > female

### *Prevalence*

- 24.6 million (9.4%) Americans reported current illicit drug use in 2013.
- 8.8% for age 12 to 17 years; 21.5% for age 18 to 25 years
- Nearly one in five young adult men use marijuana.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

Multifactorial, including genetic, environmental

### *Genetics*

Substances of abuse affect dopamine, acetylcholine, &ggr;-aminobutyric acid, norepinephrine, opioid, and serotonin receptors. Variant alleles may account for susceptibility to disorders.

## **RISK FACTORS**

- Male gender, young adult
- Depression, anxiety
- Other substance use disorders

- Family history
- Peer or family use or approval
- Low socioeconomic status
- Unemployment
- Accessibility of substances of abuse
- Family dysfunction or trauma
- Antisocial personality disorder
- Academic problems, school dropout
- Criminal involvement

## GENERAL PREVENTION

- Early identification and aggressive early intervention improve outcomes.
- Universal school-based interventions are modestly effective for preventing drug use among adolescents.

## COMMONLY ASSOCIATED CONDITIONS

- Depression
- Personality disorders
- Bipolar affective disorder

### **ALERT**

*Prescription* narcotic overdose is the leading cause of accidental death between the ages of 25 and 45 years in the United States; this correlates with increased prescribing of long-acting oxycodone (see [www.cdc.gov/injury/wisqars/pdf/leading\\_causes\\_of\\_death\\_by\\_age\\_group\\_2013-a.pdf](http://www.cdc.gov/injury/wisqars/pdf/leading_causes_of_death_by_age_group_2013-a.pdf)).

## **DIAGNOSIS**

Substance use disorder (*DSM-5* criteria): <sup>32</sup> of the following in past year, with severity based on number of criteria present:

- Missed work or school
- Use in hazardous situations

- Continued use despite social or personal problems
- Craving
- Tolerance (decreased response to effects of drug due to constant exposure)
- Withdrawal upon discontinuation
- Using more than intended
- Failed attempts to quit
- Increased time spent obtaining, using, or recovering from the substance
- Interference with important activities
- Continued use despite health problems

## **HISTORY**

- History of infections (e.g., endocarditis, hepatitis B or C, TB, STI, or recurrent pneumonia)
- Social or behavioral problems, including chaotic relationships and/or employment
- Frequent visits to emergency department
- Criminal incarceration
- History of blackouts, insomnia, mood swings, chronic pain, repetitive trauma
- Anxiety, fatigue, depression, psychosis

## ***PHYSICAL EXAM***

- Abnormally dilated or constricted pupils
- Needle marks on skin
- Nasal septum perforation (with cocaine use)
- Cardiac dysrhythmias, pathologic murmurs
- Malnutrition with severe dependence

## ***DIFFERENTIAL DIAGNOSIS***

- Depression, anxiety, or other mental states
- Metabolic delirium (hypoxia, hypoglycemia, infection, thiamine deficiency, hypothyroidism, thyrotoxicosis)
- ADHD

- Medication toxicity

## DIAGNOSTIC TESTS & INTERPRETATION

### ALERT

Screening: a single question: "How many times in the past year have you used an illegal drug or used a prescription medication for nonmedical reasons?": in primary care setting, resulted in sensitivity of 100% and specificity of ~75% (1) [B]

- CRAFFT questionnaire is superior to cut down, annoyed by criticism, guilty about drinking, eye-opener drinks (CAGE) for identifying alcohol use disorders in adolescents and young adults; sensitivity is 94% with 32 Yes answers.
  - C: Have you ever ridden in a car driven by someone (including yourself) who was high or who had been using alcohol or drugs?
  - R: Do you ever use alcohol or drugs to relax, feel better about yourself, or fit in?
  - A: Do you ever use alcohol or drugs while you are alone?
  - F: Do you ever forget things you did while using alcohol or drugs?
  - F: Do your family or friends ever tell you that you should cut down on your drinking or drug use?
  - T: Have you gotten into trouble while you were using alcohol or drugs?
- Blood alcohol concentration
- Urine drug screen (UDS) (order qualitative UDS, and if specific drug is in question, a quantitative analysis for specific drug; order confirmatory serum tests if you suspect false positive)
- Approximate detection limits
  - Alcohol: 6 to 10 hours
  - Amphetamines and variants: 2 to 3 days
  - Barbiturates: 2 to 10 days
  - Benzodiazepines: 1 to 6 weeks
  - Cocaine: 2 to 3 days
  - Heroin: 1 to 1.5 days
  - LSD, psilocybin: 8 hours

- Marijuana: 1 day to 4 weeks
  - Methadone: 1 day to 1 week
  - Opioids: 1 to 3 days
  - PCP: 7 to 14 days
  - Anabolic steroids: oral, 3 weeks; injectable, 3 months; nandrolone, 9 months
- Liver transaminases
  - HIV, hepatitis B and C screens
  - Echocardiogram for endocarditis
  - Head CT scan for seizure, delirium, trauma

## TREATMENT

Determine substances abused early (may influence disposition).

P.999

## GENERAL MEASURES

- Nonjudgmental, medically oriented attitude
- Motivational interviewing and brief interventions can overcome denial and promote change.
- Behavioral and cognitive therapy
- Community reinforcement
- Interventional counseling
- Self-help groups to aid recovery (Alcoholics Anonymous, other 12-step programs)
- Support groups for family (Al-Anon and Alateen)

## MEDICATION

- Alcohol withdrawal: See "Alcohol Abuse and Dependence" and "Alcohol Withdrawal."
- Benzodiazepine or barbiturate withdrawal
  - Gradual taper preferable to abrupt discontinuation
  - Substitution of long-acting benzodiazepine or phenobarbital
- Nicotine withdrawal: See "Tobacco Use and Smoking Cessation."

## Opioid withdrawal

- Methadone: 20 mg/day PO; use restricted to inpatient settings and specially licensed clinics (2)[A]
- Clonidine: 0.1 to 0.2 mg PO TID for autonomic hyperactivity (3)[A]
- Buprenorphine: 8 to 16 mg/day sublingually; may precipitate a more severe withdrawal if initiated too soon; use restricted to licensed clinics and certified physicians (4)[A]
- Stimulant withdrawal
  - No agent with clear benefit for cocaine
  - Anti-cocaine vaccine in development
  - Naltrexone: 50 mg PO twice weekly reduces amphetamine use in dependent patients (5)[B].
  - Methylphenidate ER: titrated up to 54 mg/day PO might enhance abstinence in amphetaminedependent patients
- Adjuncts to therapy
  - Use all medications in conjunction with psychosocial behavioral interventions.
  - Antiemetics, nonaddictive analgesics for opioid withdrawal
  - Nonhabituating antidepressants, mood stabilizers, anxiolytics, and hypnotics for comorbid mood and anxiety disorders and insomnia that persist after detoxification
- Contraindications
  - Buprenorphine in lactation
  - Naltrexone in pregnancy, liver disease
- Precautions: Clonidine can cause hypotension.
- Significant possible interactions
  - Buprenorphine and ketoconazole, erythromycin, or HIV protease inhibitors
  - Naltrexone and opioid medications (may precipitate or exacerbate withdrawal)

## *ISSUES FOR REFERRAL*

- Consider addiction specialist, especially for opioid and polysubstance abuse.
- Maintenance therapy for opioid dependence (e.g., methadone) only in licensed clinics
- Psychiatrist for comorbid psychiatric disorders

- Social services

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Indications for inpatient detoxification
  - History of withdrawal symptoms (e.g., seizures)
  - Disorientation
  - Hallucinations or psychotic features
  - Threat of harm to self or others
  - Obstacles to close monitoring (follow-up)
  - Comorbid medical illness
  - Pregnancy
- For narcotic addiction and withdrawal
- Look for signs of severe infection (e.g., bacterial endocarditis).

### *IV Fluids*

Maintenance until patient is taking fluids well by mouth

### *Nursing*

- Take frequent vital signs during withdrawal.
- Monitor for signs of drug use in the hospital.

### *Discharge Criteria*

- Detoxification complete
- Rehabilitation plan in place

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Initially frequent visits to monitor for medical stability and adherence, then progressive follow-up intervals

## *Patient Monitoring*

Verify patient's compliance with the substance abuse treatment program.

## *DIET*

Patients often are malnourished.

## *PATIENT EDUCATION*

- Substance Abuse and Mental Health Services Administration: <http://www.samhsa.gov/> or 800-662-HELP for information, treatment facility locator
- National Institute on Drug Abuse: <http://www.drugabuse.gov/patients-families> and <http://www.drugabuse.gov/nidamed-medical-health-professionals/tool-resources-your-practice/patient-materials>
- Alcoholics Anonymous: <http://www.aa.org/>
- Narcotics Anonymous: <http://www.na.org.za/>

## *PROGNOSIS*

- Patients in treatment for longer periods (<sup>3</sup>1 year) have higher success rates.
- Behavioral therapy and pharmacotherapy are most successful when used in combination.

## **COMPLICATIONS**

- Serious harm to self and others: accidents, violence
- Overdoses resulting in seizures, arrhythmias, cardiac and respiratory arrest, coma, death
- Hepatitis, HIV, tuberculosis, syphilis
- Subacute bacterial endocarditis
- Malnutrition
- Social problems, including arrest
- Poor marital adjustment and violence
- Depression, schizophrenia
- Sexual assault (alcohol, flunitrazepam, GHB)

**&NA;**

Alcohol Abuse and Dependence; Alcohol Withdrawal; Tobacco Use and Smoking Cessation

## Codes

**&NA;**

## **ICD10**

- F19.10 Other psychoactive substance abuse, uncomplicated
- F10.10 Alcohol abuse, uncomplicated
- F12.10 Cannabis abuse, uncomplicated

## **Clinical Pearls**

**&NA;**

- Substance use disorders are prevalent, serious, and often unrecognized in clinical practice. Comorbid psychiatric disorders are common.
- Substance abuse is distinguished by family, social, occupational, legal, or physical dysfunction that is caused by persistent use of the substance.
- Dependence is characterized by tolerance, withdrawal, compulsive use, and repeated overindulgence.
- Motivational interviewing, brief interventions, and a nonjudgmental attitude can help to promote a willingness to change behavior. Research shows the benefit of referring patients with alcohol dependence to an addiction specialist or treatment program.

# Suicide

Irene C. Coletsos, MD

Harold J. Bursztajn, MD

## BASICS

### DESCRIPTION

Suicide and attempted suicide are significant causes of morbidity and mortality.

### EPIDEMIOLOGY

- Predominant sex
  - Women *attempt* suicide 1.5 times more often than men. Men *complete* suicide 4 times more often than women. Men are more likely to choose a means with high lethality.
- Predominant age: adolescent (2nd leading cause of death, 10th leading cause of death overall, per 2013 CDC statistics [latest available]);
- Predominant race: 84% of people who complete suicides are white, non-Hispanic. Native Americans have the next highest rate in the United States. Whites have twice the risk of suicide compared with African Americans.
- Marital status: single > divorced; widowed > married
- Worldwide, in of all countries, youths (ages 10 to 24 years) are the highest risk group.

### Incidence

- In 2013, 10th leading cause of death in adults in the United States. Military service (not specifically active duty) is associated with increased risk. In 2009, 2010, 2012, and 2013, more soldiers died of suicide than in active duty, according to a congressional study and the National Center for Veterans.
- Worldwide, the 3rd leading cause of death.

### RISK FACTORS

- Human understanding is the most effective weapon against suicide. The greatest need is to deepen the awareness and sensitivity of people to their fellow man (Shneidman, American

Association of Suicidology).

- Be alert to a combination of *ÒperturbationÓ* (increased emotional disturbance) and *ÒlethalityÓ* (having the potential tools to cause death).
- 80% who complete suicides had a previous attempt.
- 90% who complete suicide meet *Diagnostic and Statistical Manual* criteria for Axis I or II disorders: major depression, bipolar disorder, anorexia nervosa, panic disorder, borderline, and antisocial personality disorders. Schizophrenia or acute onset of psychosis are also risk factors, due to command hallucinations or even the negative affect or hopelessness that can accompany these states.
- Substance use (alcohol, hallucinogens, opioids)
- Family history of suicide
- Physical illness
- Despair: feeling unendurable emotional pain *and* has *Ògiven upÓ* on self, feels without hope and, consciously or unconsciously, unworthy of help
- Among teenagers: not feeling *ÒconnectedÓ* to their peers or family; being bullied; poor grades
- Psychosocial: recent loss: What may seem to be a small loss (to a medical provider) may be a devastating loss to the patient. *Patient-specific* factors need to be taken into account: social isolation, anniversaries, and holidays. Patients who attempt suicide also seem to have impaired decision-making skills and risk awareness, and increased impulsivity, compared with patients who have never attempted suicide (1).
- If a patient is incompetent (e.g., too delusional) to inform providers about the potential for suicide, that puts the patient at increased risk, consider hospitalization.
- Access to lethal means: firearms, poisons (including prescription and nonprescription drugs)

## GENERAL PREVENTION

- Know how to access resources 24/7 within and outside of the health care institution.
- Screen for risk factors, and consider the overall clinical picture. Screening instruments include the Patient Health Questionnaire-2 (PHQ-2), the PHQ-9, the Columbia Suicide Severity Rating Scale, Beck's Scale for Suicidal Ideation, Linehan's Reasons for Living Inventory, and Risk Estimator for Suicide.
- Treat underlying mental illness and substance abuse. Screen for possession of means of harm, including prescription and nonprescription drugs and firearms (encourage these patients to remove guns from their homes and to relinquish gun licenses).
- Women being treated for cancer, chronic obstructive pulmonary disease (COPD), heart

disease, osteoporosis, or stroke were found to be at higher risk for suicide (even without a history of depression).

- Create a safety plan for patients at risk for suicide and their families, including education about how to access emergency care 24 hours a day.
- Public education about how to help others access emergency psychiatric care. Suicidal people may first confide in those they trust outside health care (e.g., family members, religious leaders, community elders, healers, hairdressers, and bartenders).
- For the military: multiple resources: [www.realwarriors.net](http://www.realwarriors.net). Suggested treatments include cognitive restructuring techniques (that their experience with adversity can be a source of strength) and help with problem-solving (so the service member does not feel like a burden) therapeutic martial arts training; focus on Vets' helping others: "Power of 10" initiative (any helpful contact could save a life).
- For teens, young adults, and their educators: suggestions and advice for students/families and educators: [www.cdc.gov/healthyyouth/adolescenthealth](http://www.cdc.gov/healthyyouth/adolescenthealth); <http://www.stopbullying.gov>
- In developing world countries, pesticide ingestion is a common method of suicide. Limiting free access has led to reduced suicide rates.

## DIAGNOSIS

### HISTORY

- Depressed patients should be asked about ideation and about a plan:
  - "Have you ever felt that life isn't worth living? Do you ever wish you could go to sleep and not wake up? Are you having thoughts about killing yourself?"
- Use psychodynamic formulation, which combines mental-state exam (i.e., behavior, mood, mental content, judgment), past history (i.e., what resources has the patient used in the past for support and are they currently available?), and history of current illness. If the patient is experiencing a loss, is under stress, and does not have access to a previously sustaining resource (e.g., a significant other, a pet, sports ability, a job), that patient is under increased risk for suicide.
- Prior attempts: precipitants, lethality, intent to die, precautions taken to avoid being rescued, reaction to survival (a patient who is upset that the suicide was not completed is at increased risk)
- History of psychiatric symptoms, substance abuse. Also note strengths, such as reasons to live, hopes for future, social supports. A patient without these is

at increased risk.

- Collateral history is important (from friends, family, physicians). It may be appropriate to break confidentiality if patient is at imminent risk of suicide.

## PHYSICAL EXAM

- Medical conditions: delirium, intoxication, withdrawal, medication side effects
- Psychosis: Observe for signs of/ask about command auditory hallucinations to kill oneself, delusional guilt, and persecutory delusions.
- In adults: Observe for signs of hopelessness/despair (see *Risk Factors*).
- In teens: Screen for risk factors: substance abuse, bullying and social isolation (both common via electronic media), poor grades, because teens may not appear depressed.

## DIFFERENTIAL DIAGNOSIS

Differentiate between patients and pseudopatients (i.e., those who are using suicide threats and gestures to manipulate others).

## DIAGNOSTIC TESTS & INTERPRETATION

### *Diagnostic Procedures/Other*

Brief tests that could be part of any medical/mental health assessment:

- PHQ-9: <http://www.med.umich.edu/1info/FHP/practiceguides/depress/phq-9.pdf>
- Columbia Suicide Severity Rating Scale, clinical instructions accessed at: [http://www.cssrs.columbia.edu/scales\\_practice\\_cssrs.html](http://www.cssrs.columbia.edu/scales_practice_cssrs.html)
- Suicide Trigger Scale version 3 (STS-3), which measures a patient's *rumination* (self-critical, repetitive thoughts) and *frantic hopelessness* (feeling trapped, suicide is the only choice): <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3443232/>

## TREATMENT

### GENERAL MEASURES

- Patients expressing active suicidal thoughts or who made an attempt require immediate evaluation for risk factors, mental status, and capacity (to determine if they are able/or willing to inform treaters about suicidal intentions), as well as a formal psychiatric consultation. Careful primary care screening can be as effective at identifying risk as a psychological

assessment.

- Cognitive therapy decreased reattempt rate in prior suicide attempters by half. (i) Establish therapeutic alliance. Have patient tell a story about recent suicidal thought or action. (ii) Help patient develop the skills needed to deal with the thoughts or feelings that trigger suicidal crises. (iii) Have patient imagine being in the situation that brought on the earlier crisis, but this time, guide that patient to practice problem-solving strategies—reinforcing the use of coping skills, rather than suicidal actions (2)[B],(3).
- Psychotherapy with suicidal patients is a challenge even for the most experienced clinicians. The countertransference, a clinician's feelings toward

P.1001

a patient, can evolve into wanting to be rid of the patient. If the patient detects this, the risk of suicide is heightened. The clinician can avoid this by recognizing countertransference and bearing it within so that the patient remains unaware (4).

- Among military personnel: ACE campaign: Ask about suicidal thoughts; care for the person, including removing access to lethal weapons; Escort the soldier for help: an emergency room, to calling 911, or a support hotline such as (800) 273-TALK (8255); text: 838255

## *MEDICATION*

- Psychopharmacology is not a substitute for getting to know the patient (5)[A].
- Patients are at increased risk of suicide at the outset of antidepressant treatment and when it is discontinued. Consider tapering/switching medical therapies rather than sudden discontinuation. Monitor carefully at these times.
- Anxiety, agitation, and delusions increasing in intensity are risk factors for suicide and should be treated aggressively.
- In patients with mood disorders, a meta-analysis of randomized, controlled trials found that lithium reduced the risk of death by suicide by 60% (5)[A].
- Agitated or combative patients may require sedation with IV or IM benzodiazepines and/or antipsychotics. Clinical response is typically seen within 20 to 30 minutes if given IM/IV.

## *Pediatric Considerations*

FDA posted black box warning for antidepressant use in the pediatric population after increased suicidality was noted. If risk of untreated depression is sufficient to warrant treatment with antidepressants, children must be monitored closely for suicidality.

## *First Line*

ECGs before prescribing or continuing antidepressants or antipsychotics to look for QT

prolongation

## ***ISSUES FOR REFERRAL***

Consider a psychiatric consult. All decisions regarding treatment must be carefully documented and communicated to all involved health care providers.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Inpatient hospitalization, if patient is suicidal with a plan to act or is otherwise at high risk; if immediate risk for self-harm, may be hospitalized involuntarily
- Immediately after a suicide attempt, treat the medical problems resulting from the self-harm before attempting to initiate psychiatric care.
- Order lab work (e.g., solvent screen, blood and urine toxicology screen, aspirin and acetaminophen levels). Patients may not disclose ingestions if they wish to succeed in their attempt or if they are undergoing mental status changes.
- Risk for self-harm continues even in hospital setting. Immediate search for and remove potentially dangerous objects, one-to-one constant observation, medication. Mechanical restraints only if necessary for patient safety
- The period after transfer from involuntary to voluntary hospitalization is also a time of high risk.

### ***Discharge Criteria***

- No longer considered a danger to self/others
- Clinicians should be aware that a patient may *claim* that he or she is no longer suicidal in order to facilitate discharge and complete the act. Look for clinical and behavioral signs that the patient truly is no longer in despair and is hopeful, such as improved appetite, sleep, engagement with staff, and group therapy. Clinicians should check with family and ancillary staff because patients may share more information with them than with doctors.
- Provide information about 24/7 resources.

## **ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

### ***Patient Monitoring***

- Increase monitoring at the beginning of treatment, when changing medications, and on discharge.
- Educate family members and other close contacts/confidants to the warning signs of suicidality. For adults: despair/hopelessness, isolation, discussing suicide, stating that the world would be a "better place" without them, losses in areas key to the patient's self-worth. For youths: may exhibit the same signs and symptoms, but one should be aware of these additional risks: history of abuse (e.g., sexual, physical), bullying in person or via electronic media (e.g., text messages or social Web sites), family stress, changes in eating and sleeping patterns, suicidality of friends, and giving away treasured items
- Make sure that the patient is willing to accept the type of follow-up offered. Do not assume that just setting it up is sufficient protection.
- Curtail access to firearms.
- Limiting the number of pills may be appropriate for an impulsive patient. However, clinicians may believe that by simply limiting the number of pills they prescribe, they are preventing further suicide attempts, an example of "magical thinking." Clinicians who find themselves thinking this way can take it as a warning sign that their patients may actually be at increased risk of suicide.

## ***PATIENT EDUCATION***

Patients who feel they are in danger of hurting themselves should consider one or several of these options:

- Call 911.
- Go directly to an emergency room.
- If already in counseling, contact that therapist immediately.
- Call the National Suicide Prevention Hotline at (800) 273-TALK (8255).
- Servicemen and servicewomen and their families can call (800) 796-9699; if there is no immediate answer, call (800) 273-TALK (8255); text 838255.

## ***PROGNOSIS***

The key to a favorable course and prognosis is early recognition of risk factors, early diagnosis and treatment of a psychiatric disorder, and appropriate intervention and follow-up.

## **COMPLICATIONS**

- According to the American Association of Suicidality (AAS), the grief process for significant others of suicide victims can be lifelong and can be expressed

in emotions ranging from anger to despair. Survivors often attempt to shoulder the burden on their own because of the added guilt and shame of the nature of the attempted death or death.

- The AAS recommends the following:
  - Counseling: could include short-term behavioral therapy as well as psychotherapy; some therapy should focus on the survivors' relationships to their current and future significant others. Survivors often seek out life partners as “replacements” for those they lost—could interfere with mourning (6).
  - Sympathetic listening by friends
  - Support during holidays
  - More self-help strategies: [www.survivorsofsuicide.com](http://www.survivorsofsuicide.com)

## Codes

**&NA;**

### ICD10

- R45.851 Suicidal ideations
- T14.91 Suicide attempt
- Z91.5 Personal history of self-harm

## Clinical Pearls

**&NA;**

- Key preventative measure is to listen to a patient and take steps to keep him or her safe. This could include immediate hospitalization. Questions to explore include, "Are you thinking of killing yourself?", "Who do you have to live for?", and "What should change so that you could live with your suffering?"
- Clozapine, lithium, and cognitive-behavioral therapy are associated with a reduction in the risk of suicide.
- Family members and contacts of people who have attempted or committed suicide suffer from reactions ranging from rage to despair. Their grief is often longer lasting and less well-treated because of the shame and guilt associated with the act. Encourage them to discuss this and consider counseling.

# Superficial Thrombophlebitis

Emily M. Culliney, MD, FAAFP

## BASICS

### DESCRIPTION

- Superficial thrombophlebitis is venous inflammation with secondary thrombosis of a superficial vein.
- Most common in the lower extremities (60-80%), but can occur in the upper extremities/neck.
- Generally a benign and self-limiting process, but can be painful
- Traumatic thrombophlebitis types:
  - Injury
  - IV catheter related
  - Intentional (i.e., sclerotherapy)
- Aseptic thrombophlebitis types:
  - Primary hypercoagulable states: disorders with measurable defects in the proteins of the coagulation and/or fibrinolytic systems
  - Secondary hypercoagulable states: clinical conditions with a risk of thrombosis (venous stasis, pregnancy)
- Septic (suppurative) thrombophlebitis types:
  - Iatrogenic, long-term IV catheter use
  - Infectious, mainly syphilis and psittacosis
- Mondor disease
  - Rare presentation of anterior chest/breast veins of women
- System(s) affected: cardiovascular
- Synonym(s): phlebitis; phlebothrombosis

### Geriatric Considerations

Septic thrombophlebitis is more common; prognosis is poorer.

### *Pediatric Considerations*

Subperiosteal abscesses of adjacent long bone may complicate the disorder.

### *Pregnancy Considerations*

- Associated with increased risk of aseptic superficial thrombophlebitis, especially during postpartum
- NSAIDs are contraindicated during pregnancy.

## **EPIDEMIOLOGY**

- Predominant age
  - Traumatic/IV related has no predominate age/sex.
  - Aseptic primary hypercoagulable state
    - Childhood to young adult
- Aseptic secondary hypercoagulable state
  - Mondor disease: women, ages 21 to 55 years
  - Thromboangiitis obliterans onset: ages 20 to 50 years
- Predominant sex
  - Suppurative: male = female
  - Aseptic
    - Spontaneous formation: female (55-70%)
    - Mondor: female > male (2:1)

### *Incidence*

- Septic
  - Incidence of catheter-related thrombophlebitis is 88/100,000 persons.
  - Develops in 4-8% if cutdown is performed
- Aseptic primary hypercoagulable state: antithrombin III and heparin cofactor II deficiency incidence is 50/100,000 persons.

- Aseptic secondary hypercoagulable state
  - In pregnancy, 49-fold increased incidence of phlebitis
  - Superficial migratory thrombophlebitis in 27% of patients with thromboangiitis obliterans

## Prevalence

- Superficial thrombophlebitis is common.
- 1/3 of patients in a medical ICU develop thrombophlebitis that eventually progresses to the deep veins.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Similar to deep venous thrombosis. Virchow triad of vessel trauma, stasis, and hypercoagulability (genetic, iatrogenic, or idiopathic)
- Varicose veins play a primary role in etiology of lower extremity phlebitis
- Mondor disease pathophysiology not completely understood
- Less commonly due to infection (i.e., septic)
  - *Staphylococcus aureus*, *Pseudomonas*, *Klebsiella*, *Peptostreptococcus* sp.
  - *Candida* sp.
- Aseptic primary hypercoagulable state
  - Due to inherited disorders of hypercoagulability
- Aseptic secondary hypercoagulable states
  - Malignancy (Trousseau syndrome: recurrent migratory thrombophlebitis): most commonly seen in metastatic mucin or adenocarcinomas of the GI tract (pancreas, stomach, colon, and gallbladder), lung, prostate, and ovary
  - Pregnancy
  - Estrogen based oral contraceptives
  - Behçet, Buerger, or Mondor disease

## Genetics

Not applicable other than hypercoagulable states

## RISK FACTORS

- Nonspecific
  - Varicose veins
  - Immobilization
  - Obesity
  - Advanced age
  - Postoperative states
- Traumatic/septic
  - IV catheter (plastic > coated)
  - Lower extremity IV catheter
  - Cutdowns
  - Cancer, debilitating diseases
  - Burn patients
  - AIDS
  - IV drug use
- Aseptic
  - Pregnancy
  - Estrogen-based oral contraceptives
  - Surgery, trauma, infection
  - Hypercoagulable state (i.e., factor V, protein C or S deficiency, others)
- Thromboangiitis obliterans: persistent smoking
- Mondor disease
  - Breast cancer or breast surgery

## **GENERAL PREVENTION**

- Avoid lower extremity cannulations/IV.
- Insert catheters under aseptic conditions, secure cannulas, and replace every 3 days.
- Avoid stasis and use usual deep vein thrombosis (DVT) prophylaxis in high-risk patients (i.e., ICU, immobilized)

## COMMONLY ASSOCIATED CONDITIONS

- Frequently seen with concurrent DVT (6-53%)
- Symptomatic pulmonary embolism can also be seen concurrently (0-10%)
- Both DVT/PE can occur up to 3 months after onset of phlebitis.

## DIAGNOSIS

### HISTORY

Pain along the course of a vein

### PHYSICAL EXAM

- Swelling, tenderness, redness along the course of a vein or veins
- May have a palpable cord along the course of the vein
- May look like localized cellulitis or erythema nodosum
- Fever in 70% of patients in septic phlebitis
- Sign of systemic sepsis in 84% of suppurative cases

### DIFFERENTIAL DIAGNOSIS

- Cellulitis
- DVT
- Erythema nodosum
- Cutaneous polyarteritis nodosa
- Lymphangitis

### DIAGNOSTIC TESTS & INTERPRETATION

#### *Initial Tests (lab, imaging)*

Often none necessary if afebrile, otherwise healthy

- Small or distal veins (i.e., forearms or below the knee): no recommended imaging
- If concern for more proximal extension: venous Doppler US to assess extent of thrombosis and rule out DVT

## Follow-Up Tests & Special Considerations

- If suspicious for sepsis
  - Blood cultures (bacteremia in 80-90%)
  - Consider culture of the IV fluids being infused.
  - CBC demonstrates leukocytosis.
- Aseptic: evaluation for coagulopathy if recurrent or without another identifiable cause (e.g., protein C and S, lupus anticoagulant, anticardiolipin antibody, factor V and VIII, homocysteine)

P.1003

- In migratory thrombophlebitis, have a high index of suspicion for malignancy.
- Repeat venous ultrasound to assess effectiveness of therapy.
  - If thrombosis is extending, more aggressive therapy required.

## Test Interpretation

The affected vein is enlarged, tortuous, and thickened with endothelial damage and necrosis.

## TREATMENT

### GENERAL MEASURES

- Suppurative: consultation for urgent surgical venous excision
- Local, mild
  - Conservative management, antibiotics not useful
  - For varicosities
    - Compression stockings, maintain activities
  - Catheter/trauma associated
    - Immediately remove IV and culture tip.
    - Elevate with application of warm compresses.
    - If slow to resolve, consider LMWH.
- Large, severe, or septic thrombophlebitis
  - Inpatient care or bed rest with elevation and local warm compress

- When the patient is ambulating, then start compression stockings or Ace bandages.

## *MEDICATION*

### *First Line*

- Best medication(s) and duration of treatment are not well-defined (1)[A].
- Localized, mild thrombophlebitis (usually self-limited)
  - NSAIDs and ASA for inflammation/pain to reduce symptoms and local progression.
  - Use of compression stockings can also provide symptomatic relief (2).

### *Second Line*

- Septic/suppurative
  - May present or be complicated by sepsis
  - Requires IV antibiotics (broad spectrum initially) and anticoagulation
- Increasing evidence shows that LMWH/fondaparinux treatment can prevent extension of superficial venous thrombosis in addition to VTE prevention.
- Consider if thrombus present in the large veins or involving the long saphenous vein
  - To prevent venous thromboembolism (VTE), 4 weeks of LMWH; such as enoxaparin
  - 45 days of fondaparinux was found to reduce DVT and VTE by 85% (relative risk reduction) in one large study (3)[B].
- Superficial thrombophlebitis related to inherited or acquired hypercoagulable states is addressed by treating the related disease.

## *ISSUES FOR REFERRAL*

Severely inflamed or very large phlebitis should be evaluated for excision.

## *SURGERY/OTHER PROCEDURES*

- Septic
  - Surgical consultation for excision of the involved vein segment and involved tributaries
  - Drain contiguous abscesses.
  - Remove all associated cannula and culture tips.

Aseptic: Manage underlying conditions.

- Evaluate for saphenous vein ligation to prevent deep vein extension after acute phase resolved.
- Consider referral for varicosity excision.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Septic: inpatient
- Aseptic: outpatient

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- Septic: routine WBC count and differential. Target treatment based on culture results.
- Severe aseptic
  - Repeat venous Doppler US in 1 to 2 weeks to ensure no DVT and assess treatment effectiveness: Do not expect resolution, just nonprogression.
  - Repeat clotting studies.
- Local, mild thrombophlebitis typically resolves with conservative therapy and does not require specific monitoring unless there is a failure to resolve.

## *DIET*

No restrictions

## *PATIENT EDUCATION*

Review local care, elevation, and use of compression hose for acute treatment and prevention of recurrence.

## *PROGNOSIS*

- Septic/suppurative

High mortality (50%) if untreated

- Depends on treatment delay or need for surgery
- Aseptic
  - Usually benign course; recovery in 2 to 3 weeks
  - Depends on development of DVT and early detection of complications
  - Aseptic thrombophlebitis can be isolated, recurrent, or migratory.
  - Recurrence likely if related to varicosity or if severely affected vein not removed

## COMPLICATIONS

- Septic: systemic sepsis, bacteremia (84%), septic pulmonary emboli (44%), metastatic abscess formation, pneumonia (44%), subperiosteal abscess of adjacent long bones in children
- Aseptic: DVT (6-53%), VTE (up to 10%), thromboembolic phenomena

deep vein thrombosis and pulmonary embolism: a systematic review. *Haematologica*. 2005;90(5):672-677.

## See Also

&NA;

Deep Vein Thrombophlebitis

## Codes

&NA;

### ICD10

- I80.9 Phlebitis and thrombophlebitis of unspecified site
- I80.00 Phlbits and thombophlb of superfic vessels of unsp low extrm
- I80.8 Phlebitis and thrombophlebitis of other sites

## Clinical Pearls

&NA;

- Mild superficial thrombophlebitis is typically selflimiting and responds well to conservative care.
- Lower extremity disease involving large veins or proximal saphenous vein may benefit from anticoagulation to prevent DVT.
- Septic thrombophlebitis requires admission for antibiotics and anticoagulation. If severe, consider surgical consultation for venous excision.

# Syncope

Santiago O. Valdes, MD, FAAP

## BASICS

### DESCRIPTION

- Transient loss of consciousness characterized by unresponsiveness, loss of postural tone, and spontaneous recovery; usually caused by cerebral hypoxemia
- System(s) affected: cardiovascular, nervous

### EPIDEMIOLOGY

#### Incidence

- Up to 20% of adults will have <sup>3</sup>1 episode by age 75 years; 15% of children <18 years of age
- Accounts for 1-6% of hospital admissions and ÷3% of emergency room visits
- Annually prevalence of fainting spells resulting in medical evaluation was 9.5/1,000 inhabitants (1).

#### Prevalence

In institutionalized elderly (>75 years of age) is 6%

### ETIOLOGY AND PATHOPHYSIOLOGY

- In some cases, vagal response leads to decreased heart rate.
- Systemic hypotension secondary to decreased cardiac output and/or systemic vasodilation leads to a drop in cerebral perfusion and resulting loss of consciousness.
- Cardiac (obstruction to outflow)
  - Aortic stenosis
  - Hypertrophic cardiomyopathy
  - Pulmonary embolus
- Cardiac arrhythmias

- Sustained ventricular tachycardia (VT)
- Supraventricular tachycardia (SVT) (atrial fibrillation, atrial flutter, reentrant SVT)
- 2nd- and 3rd-degree AV block
- Sick sinus syndrome
- Noncardiac
  - Reflex-mediated vasovagal (neurocardiogenic/neurally mediated), situational (micturition, defecation, cough, hair combing)
  - Orthostatic hypotension
  - Drug induced
  - Neurologic: seizures; transient ischemic attack (can in theory cause syncope but presentation usually markedly clinically different from pure syncope)
  - Carotid sinus hypersensitivity
  - Psychogenic

## *Genetics*

Specific cardiomyopathies and arrhythmias may be familial (i.e., long QT syndrome, catecholaminergic polymorphic VT, Brugada syndrome, hypertrophic cardiomyopathy).

## *RISK FACTORS*

- Heart disease
- Dehydration
- Drugs
  - Antihypertensives
  - Vasodilators (including calcium channel blockers, ACE inhibitors, and nitrates)
  - Phenothiazines
  - Antidepressants
  - Antiarrhythmics
  - Diuretics

## *GENERAL PREVENTION*

See ÒRisk Factors.Ó

## COMMONLY ASSOCIATED CONDITIONS

See ÒEtiology.Ó

## DIAGNOSIS

### HISTORY

- Careful history, physical exam, and an ECG are more important than other investigations in determining the diagnosis (2)[A]. Syncope associated with physical exertion suggests a potential cardiac etiology.
- Make sure that the patient or witness (if present) is not talking about vertigo (i.e., sense of rotary motion, spinning, and whirling), seizure, or causes of fall without loss of consciousness.
- Even after careful evaluation, including diagnostic procedures and special tests, the cause will be found in only 50-60% of the patients.
- Onset of syncope is usually rapid, and recovery is spontaneous, rapid, and complete. Duration of episodes are typically brief (<60 seconds). The presence of underlying cardiac or neurologic conditions provides the key to diagnosis.
- Ask for family history of long QT syndrome, hypertrophic cardiomyopathy, or unexplained sudden cardiac death in young family members.

### PHYSICAL EXAM

- BP and pulse, both lying and standing
- Check for cardiac murmur or focal neurologic abnormality.

### DIFFERENTIAL DIAGNOSIS

- Drop attacks
- Coma
- Vertigo
- Seizure disorder

### DIAGNOSTIC TESTS & INTERPRETATION

History and physical examination should guide laboratory testing.

## *Initial Tests (lab, imaging)*

Consider (not all indicated in all individuals) the following:

- CBC
- Electrolytes, BUN, creatinine, glucose (rarely helpful: <2% have hyponatremia, hypocalcemia, hypoglycemia, or renal failure causing seizures)
- Cardiac enzymes (only if history suggestive of cardiac ischemia)
- D-dimer (for pulmonary embolism workup)
- hCG
- Lung scan or helical CT scan of thorax if history and physical exam suggest pulmonary embolism (PE)

## *Follow-Up Tests & Special Considerations*

- If history and physical suggest ischemic, valvular, or congenital heart disease (3)
  - ECG (3)[A]
  - Exercise stress test (if syncope with exertion) (3)[C]
  - Echocardiogram (3)[B]
  - Cardiac catheterization
- If CNS disease suspected (3)[C]
  - EEG
  - Head CT scan
  - Head MRI/MRA when vascular cause is suspected
  - Do not order these tests without hints of CNS disease on history or physical exam.
- ECG monitoring, either in hospital or ambulatory (Holter) (3)[C]
  - Useful in 4-15% of patients
  - Should be done in patients with heart disease or recurrent syncope
  - Arrhythmias frequently documented but not always associated with syncope
- Electrophysiologic studies (3,4)[C]
  - Have been positive in 18-75% of patients
  - Induction of VT and dysfunction of His-Purkinje system are the two most common

abnormalities.

- Should be done in patients with heart disease and recurrent syncope, although they may not show whether arrhythmia noted or induced during study is cause of syncope
- Carotid hypersensitivity evaluation (3,4)[C]
  - Carotid hypersensitivity should be considered in patients with syncope during head turning, especially while wearing tight collars, and with neck tumors and neck scars.
  - The technique is not standardized; one side at a time is compressed gently for 20 seconds with constant monitoring of pulse and BP/ECG.
  - Atropine should be readily available.
- Tilt-table testing ± isoproterenol infusion (3)[B],(4)[C]
  - Provocative test for vasovagal syncope
  - Perform if cardiac causes have been excluded; role in workup of patients with syncope of unknown origin
  - Protocol is not standardized but has been reported positive (symptomatic hypotension and bradycardia) in 26-87% of patients; also positive in up to 45% of control subjects.
- Psychiatric evaluation (3)[C]: Anxiety, depression, and alcohol and drug abuse can be associated with syncope.

## *Diagnostic Procedures/Other*

Patient-activated implantable loop recorders can record 4 to 5 minutes of retrograde ECG rhythm. Helpful in selective patients with recurrent syncope, with yield of 32-80% (3,4)[B].

## *Test Interpretation*

Depends on etiology and presence of underlying cardiac or neurologic conditions

## **TREATMENT**

Maintaining good hydration status and normal salt intake are initial therapy. Educate patients of the premonitory signs of syncope (5)[B].

## **GENERAL MEASURES**

- Elderly patients without previously recognized heart disease should be admitted if the physician thinks that the cause of syncope is likely cardiac.

Patients without heart disease, especially young patients (age <60 years), can be worked up safely as outpatients.

- Prescribe antiarrhythmics for documented arrhythmias occurring simultaneously with syncope or symptoms of presyncope. Asymptomatic arrhythmias do not necessarily require treatment.
- The decision to treat patients on basis of arrhythmias or conduction abnormalities provoked or detected during EPS is even more problematic: Does the arrhythmia or conduction abnormality have anything to do with the patient's symptoms?
- Most would treat patients with provoked sustained VT with an antiarrhythmic drug that suppressed arrhythmia during study.
- Rationale for such treatment: Recurrent syncope is less frequent in patients with positive EPS who are treated than it is in those who have negative EPS.

## MEDICATION

### First Line

- Geared toward specific underlying cardiac or neurologic abnormalities
- In cases of recurrent vasovagal/neurocardiogenic/neurally mediated syncope (6)[B]
  - *&agr;*-Adrenergic agonists (midodrine)
  - Mineralocorticoids (fludrocortisone)
  - *&bgr;*-Adrenergic blockers

### Second Line

- SSRIs (paroxetine, sertraline, fluoxetine)
- Vagolytics (disopyramide)

## ISSUES FOR REFERRAL

When cardiac or neurologic etiologies are suspected, obtain appropriate consultation, as indicated.

## ADDITIONAL THERAPIES

For vasovagal/neurocardiogenic/neurally mediated syncope

- Counterpressure maneuvers, orthostatic training, and exercise have improved vasovagal symptoms and recurrence (3,5)[C].

- Head-up tilt sleeping (3)[C]
- Abdominal binders and/or support stockings (3)[C]

## ***SURGERY/OTHER PROCEDURES***

- Implantable cardioverter-defibrillator (ICD) placement for patients with cardiac conditions with high risk of sudden death and/or recurrent syncope on medications (i.e., long QT syndrome, catecholaminergic polymorphic VT, hypertrophic cardiomyopathy) (3)[B]
- Many recommend pacemaker implantation in patients with the following:
  - 2nd- (Mobitz type II) and 3rd-degree heart block
  - HV intervals > 100 ms
  - Pacing-induced infranodal block
  - Sinus node recovery time  $\geq$  3 seconds

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Patients with benign etiologies of syncope with negative ED workups are associated with benign outcomes, even in the presence of other risk factors (7)[B].

Patients with suspected cardiac or neurologic cause for syncope should be admitted to the hospital for evaluation.

- Support ABCs.
- Stabilize heart rate and BP, typically with IV fluids.

### ***IV Fluids***

Use isotonic crystalloid fluids for fluid resuscitation, if needed.

### ***Nursing***

Close monitoring of BP and heart rate during initial presentation

### ***Discharge Criteria***

- Attainment of hemodynamic stability
- Satisfactory completion of workup for etiology
- Adequate control of specific arrhythmia or seizure, if present

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Frequent follow-up visits for patients with cardiac causes of syncope, especially patients on antiarrhythmics
- Patients with an unknown cause of syncope rarely (5%) are diagnosed during the follow-up.

#### *DIET*

- No specific diet unless the patient has heart disease
- Increased fluid and salt intake to maintain intravascular volume in cases of recurrent vasovagal syncope

### *PATIENT EDUCATION*

- Reassure the patient that most cardiac causes of syncope can be treated, and patients with noncardiac causes do well, even if the cause of syncope is never discovered.
- Physical counterpressure maneuvers can prevent recurrences of vasovagal syncope.
- Physician and patient should carefully consider whether the patient should continue to drive while syncope is being evaluated. Physicians should be aware of pertinent laws in their own states.

### *PROGNOSIS*

- Cumulative mortality at 2 years
  - Low: young patients (<60 years of age) with noncardiac or unknown cause of syncope
  - Intermediate: older patients (>60 years of age) with noncardiac or unknown cause of syncope
  - High: patients with cardiac cause of syncope
- Independent predictors of poor short-term outcomes (8,9)[B]
  - Abnormal ECG
  - Shortness of breath
  - Systolic BP <90 mm Hg

- Hematocrit <30%
- Congestive heart failure

## COMPLICATIONS

- Trauma from falling
- Death (see "Prognosis")

&NA;

### ICD10

R55 Syncope and collapse

## Clinical Pearls

**&NA;**

- A careful history and physical exam are key to a diagnosis.
- Use the ECG/event-recorder to evaluate for cardiac conditions.
- True neurologic causes of syncope are very rare; by far, cardiac causes are more common.
- <2% of cases are caused by hyponatremia, hypocalcemia, hypoglycemia, or renal failure causing seizures.

# Syncope, Reflex (Vasovagal Syncope)

Melinda Y. Kwan, DO, MPH

Norton Winer, MD

## BASICS

Syncope is a reversible loss of consciousness and postural tone secondary to systemic hypotension and cerebral hypoperfusion due to vasodilation and/or bradycardia (rarely, tachycardia) with spontaneous recovery and no neurologic sequelae. The term syncope excludes seizures, coma, shock, or other states of altered consciousness.

## DESCRIPTION

- Derived from the Greek term *syncope*, meaning to cut short
- Sudden, transient loss of consciousness characterized by unresponsiveness, falling, and spontaneous recovery
- Common cause of syncope in all age groups, especially in patients with no evidence of neurologic or cardiac disease
- Four main types: vasovagal or neurocardiogenic syncope, situational syncope, orthostatic hypotension, carotid sinus hypersensitivity, and glossopharyngeal/trigeminal neuralgia syncope (uncommon) (1)

## EPIDEMIOLOGY

- Mortality: cardiac-related syncope 20-30% and 5% in idiopathic syncope
- Age: any age

## Incidence

- Ranges from 7.5% in children aged <18 years and 15% in adults aged >70 years
- 36-62% of all syncopal episodes
- 30% recurrence rate

## Prevalence

22% in the general population

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

Cause: an abnormal interaction of the normal mechanisms for maintaining BP and upright posture

- In normal individuals, upright posture results in venous pooling and transient decrease in BP.
- Neurally induced syncope may result from a cardioinhibitory response, a vasodepressor response, or a combination of the two.
- Increased cardiovagal tone leads to bradycardia or asystole and decreased peripheral sympathetic activity leads to venodilation and hypotension (2).
- Vasovagal syncope usually has a precipitating event, often related to fright, pain, panic, exercise, noxious stimuli, or heat exposure (2).
- Carotid sinus syncope is precipitated by position change, turning head, or wearing a tight collar (possible neck tumors or surgical scarring).
- Situational syncope is related to micturition, defecation, postexercise, cough, or swallow (3).
- Glossopharyngeal syncope is related to throat or facial pain (4).

## ***Genetics***

Vasovagal syncope: strong heritable component to the etiology of >20% of cases

## ***RISK FACTORS***

- Low-resting BP
- Age: older age
- Prolonged supine position with resulting deconditioning of autonomic control

## ***GENERAL PREVENTION***

Avoidance of precipitating events or situations. Optimization of diabetes mellitus (DM) control, elastic stockings, adequate hydration. Limited evidence suggests that polydipsia may reduce recurrences.

## ***COMMONLY ASSOCIATED CONDITIONS***

- Cardiopulmonary disorders: CHF, MI, arrhythmias, hypertrophic obstructive cardiomyopathy, HTN, PE pulmonary embolism
- Neurologic disorders: autonomic dysfunction, Shy-Drager, Parkinson disease, multiple system atrophy, transient ischemic attack, vertebrobasilar insufficiency, peripheral neuropathy
- Psychiatric disorders:

- Generalized anxiety disorder
- Panic disorder
- Major depression
- Alcohol dependence

## DIAGNOSIS

### HISTORY

- Evaluation of syncope and presyncope are the same.
- Important first to rule out cardiac syncope
- Neurally mediated syncope is preceded by blurred vision, palpitations, nausea, warmth, diaphoresis, or light-headedness, or there may be history of nausea, warmth, diaphoresis, or fatigue *after* syncope (5)[C].
- Vasovagal syncope
  - Three phases: prodrome, loss of consciousness, and postsyncope
  - Precipitating event or stimulus is usually identified, such as panic, fright, pain, or exercise.
  - Athletes may have after exertion (diagnosis of exclusion).
  - Position: *can be preceded by prolonged standing but can occur from any position; generally resolves when the patient becomes supine*
    - Preceding events: as discussed above
    - Prodrome: as listed above for neurally mediated syncope
  - Duration: generally brief (seconds to minutes)
  - Recovery: may be prolonged with persistent nausea, pallor, and diaphoresis but without neurologic change or confusion
- Carotid sinus syncope is precipitated by position change, after turning head, or wearing a tight collar.
- Situational syncope is related to micturition, defecation, or coughing.
- Glossopharyngeal syncope (less common) is related to throat or facial pain (4)[C]
  - Precipitating events or situations may include panic, pain, exercise, micturition, defecation, coughing, or swallowing.

## *PHYSICAL EXAM*

- Vital signs, including orthostatics and bilateral BP
- Cardiac exam: volume status, murmurs, rhythm, carotid bruits
- Neurologic exam: signs of focal deficit
- Assess for occult blood loss, including guaiac.
- Dix-Hallpike to rule out benign paroxysmal vertigo

## *DIFFERENTIAL DIAGNOSIS*

- Seizure
- Arrhythmia
- Hypoglycemia
- Cardiac syncope
- Cerebrovascular syncope
- Orthostatic hypotension
- Drop attacks
- Psychiatric illness

## *DIAGNOSTIC TESTS & INTERPRETATION*

As indicated by history and physical, includes basic tests to rule out the three main reasons for syncope: hypoglycemia, arrhythmia, and anemia

### *Initial Tests (lab, imaging)*

- Blood sugar
- ECG should be ordered for all patients. Abnormal ECG findings are common in patients with cardiac syncope.
- CBC to rule out anemia
- Head CT, MRI/MRA, carotid ultrasound only in patients whose history or physical exam suggests a neurologic cause of syncope
  - The 2007 American College of Emergency Physicians (ACEP) Guidelines for diagnostic testing for syncope are as follows (6):
    - *Level A recommendations:* standard 12-lead ECG

- *Level B recommendations*: none specified
- *Level C recommendations*: laboratory testing and investigations, including echocardiography or head CT, to be performed only if indicated by specific findings in the history or physical examination

## *Follow-Up Tests & Special Considerations*

- 24-hour Holter monitoring only in patients with a high probability of cardiac cause of syncope and/or abnormal ECG findings
- A low hemoglobin without obvious cause of bleed would warrant a guaiac, CT head to rule out subarachnoid hemorrhage (SAH), CT abdomen to rule out retroperitoneal bleed.
- Negative imaging will prompt workup for alternative causes.
- Stroke, bleed, or carotid stenosis will require appropriate disease-oriented management.
- EEG only when history or physical exam is very suggestive of seizure activity
- Implantable loop recorder

## *Diagnostic Procedures/Other*

- Head-up tilt table testing:
    - Contraindicated in patients with known cardiac or neurovascular disease or in pregnancy
    - Indicated for recurrent syncope or single episode accompanied by injury or risk to others (e.g., pilots, surgeons)
    - Uses positional changes to reproduce symptoms
    - Positive tests are diagnostic for vasovagal syncope.
  - Carotid sinus massage, only in a monitored setting (i.e., BP and HR monitoring, IV access):
    - Contraindicated in patients with carotid disease (careful auscultation prior to massage is essential)
- 
- Pressure at the angle of the jaw for 5 seconds with simultaneous ECG monitoring
  - Positive tests (causing syncope or cardiac pause >3 seconds) are diagnostic of carotid sinus syncope.
- Psychiatric evaluation: to rule out anxiety, depression, and alcohol abuse

P.1007

## TREATMENT

Therapy is primarily for recurrent syncope. Situational syncope will not warrant any treatment.

### GENERAL MEASURES

Recognition and avoidance of precipitating events or situations; medical management is based on small, nonrandomized clinical trials.

#### *First Line*

- Nonpharmacologic treatment
  - Includes patient counseling
    - Development of coping skills
    - Increased salt and fluid intake
  - Moderate exercise training
    - Isometric muscle contractions
      - Leg crossing and buttocks clenching
      - Intense gripping of the hands and tensing of the arms
      - These maneuvers increase cardiac output and arterial blood pressure (7).
  - Tilt-table training
    - Progressively prolonged periods of enforced upright posture

#### *Second Line*

- $\alpha$ -Agonists are mainly used for orthostatic hypotension.
  - Midodrine is commonly used. It increases peripheral vascular resistance and venous return. Side effects include HTN, paresthesia, urinary retention, goose bumps, hyperactivity, dizziness, tremor, and nervousness.
- SSRIs: Paroxetine and fluoxetine are SSRIs useful in treating neurocardiogenic/vasovagal syncope.
  - Serotonin affects BP and HR via the central nervous system. Serotonin decreases a sympathetic withdrawal response to rapid increases in serotonin levels.
  - Side effects include weight gain, nausea, anxiety, sexual dysfunction, and insomnia.

- Mineralocorticoids: Fludrocortisone has been found helpful mainly in orthostatic hypotension.
  - Helpful in renal sodium absorption and increasing the vasoconstrictive peripheral vascular response
  - Adverse reactions include fluid retention, HTN, CHF, peripheral edema, and hypokalemia.
- $\beta$ -Blockers: Metoprolol, atenolol, or pindolol are mainly used for postural tachycardia syndrome (POTS).
  - Block peripheral vasodilators and ventricular mechanoreceptor stimulation.
  - Stabilization of HR and BP
  - Side effects: hypotension and bradycardia (with worsening of syncope), fatigue, depression, and sexual dysfunction
  - Contraindicated in asthma

## ISSUES FOR REFERRAL

Neurology or cardiology, as needed

## ADDITIONAL THERAPIES

Use of support/pressure stockings

## COMPLEMENTARY & ALTERNATIVE MEDICINE

These include treatments for underlying heart disease or precipitating factors like anxiety. None of these are proven therapies.

- Nutrition and supplements: omega-3 fatty acids, multivitamin, CoQ10, acetyl-L-carnitine,  $\alpha$ -lipoic acid, and L-arginine
- Herbs: Green tea (*Camellia sinensis*), bilberry (*Vaccinium myrtillus*), ginkgo (*Ginkgo biloba*)
- Homeopathy: Carbo vegetabilis, opium, sepia
- Acupuncture: It may precipitate fainting.

## SURGERY/OTHER PROCEDURES

Pacemaker placement may be of use in patients with frequent neurocardiogenic/vasovagal syncope that is refractory to other therapies (3)[C].

- Prevents prolonged bradycardia or asystole during syncopal episodes
- Long-term effect

- Invasive placement procedure

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

2007 ACEP guidelines mandate that the patient be admitted if (6):

- *Level B recommendations*
  - Admit patients with syncope and evidence of heart failure or structural heart disease.
  - Admit patients with syncope and high-risk factors.
- High-risk stratification is based on the following factors:
  - Older age and associated comorbidities
  - Abnormal ECG, hematocrit (Hct) 30 (if obtained)
  - History or presence of heart failure, coronary artery disease, or structural heart disease
- Additional causes to admit
  - Syncope occurring during exercise
  - Syncope causing severe injury
  - Family history of sudden death
- IV fluids to stabilize HR and BP

### *IV Fluids*

Isotonic crystalloids, as needed

### *Nursing*

Vital sign monitoring

### *Discharge Criteria*

Hemodynamically stable and workup satisfactory

## **ONGOING CARE**

### *DIET*

- Increased salt intake may be helpful if not contraindicated (2)[C].

- Maintain fluid intake.

## **PATIENT EDUCATION**

- To identify and avoid precipitating events or situations
- Avoid dehydration, alcohol consumption, warm environments, tight clothing, and long periods of standing motionless.
- Recognize presyncopal symptoms.
- Use behaviors, such as lying down, to avoid syncope.

## **PROGNOSIS**

May be recurrent but not life-threatening

## **COMPLICATIONS**

May result in injury from fall

## See Also

&NA;

Algorithms: Syncope; Transient Ischemic Attack and Transient Neurologic Defects

## Codes

&NA;

### ICD10

R55 Syncope and collapse

## Clinical Pearls

&NA;

- History should include a careful analysis of the events preceding the attack.
- It is important to rule out cardiologic or neurologic pathology.
- Prodrome is often present.
- Recovery may be prolonged, with persistent symptoms but no neurologic deficit or confusion.
- Patient counseling to avoid precipitating situations or events is the first-line treatment.
- Pregnant females can have reflex syncope when moving from supine to lateral decubitus or upright positions.

# Syndrome of Inappropriate Antidiuretic Hormone Secretion (SIADH)

Elise J. Barney, DO

## BASICS

### DESCRIPTION

- A syndrome of abnormal production of antidiuretic hormone (ADH), despite low serum osmolality, leading to hyponatremia and inappropriately elevated urine osmolality
  - Resulting abnormal urinary free water retention leads to dilutional hyponatremia (total body sodium levels may be normal or near normal, but the patient's total body water is increased).
  - Often secondary to medications but may be associated with an underlying disorder, such as neoplasm, pulmonary disorder, or CNS system disease
- Synonym(s): syndrome of inappropriate secretion of ADH

### EPIDEMIOLOGY

#### *Incidence*

- Often found in the hospital setting, where incidence can be as high as 35%
- Predominant age: elderly
- Predominate sex: females > males

### ETIOLOGY AND PATHOPHYSIOLOGY

- Drugs:
  - Antidepressants (e.g., monoamine oxidase inhibitors [MAOIs], tricyclics, SSRIs)
  - Antineoplastic drugs (e.g., vincristine, vinblastine, cisplatin, cyclophosphamide)
  - Antipsychotic agents (e.g., phenothiazines, thioridazine, haloperidol)
  - Analgesics (e.g., NSAIDs)
  - Antiepileptics (e.g., carbamazepine, oxcarbazepine, valproic acid)

- Oral hypoglycemics (e.g., chlorpropamide, metformin)
- Others (e.g., vasopressin, DDAVP, oxytocin, ciprofloxacin, &agr;-interferon, ecstasy)
- Neoplasms (ectopic ADH production):
  - Bronchogenic carcinoma
  - Hodgkin disease
  - Mesothelioma
  - Oat cell carcinoma of the lung
  - Pancreatic carcinoma
  - Small cell carcinoma of the lung
  - Thymoma
- Pulmonary conditions:
  - Asthma/COPD
  - Atelectasis
  - Cystic fibrosis
  - Positive pressure mechanical ventilation
  - Pneumonia
  - Pulmonary tuberculosis (TB)
  - Sarcoidosis
- Neurological causes:
  - Acute porphyria
  - CNS injury (i.e., SAH, trauma, stroke)
  - CNS lupus
  - Encephalitis
  - Epilepsy
  - Guillain-BarrŽ syndrome
  - Meningitis
  - Multiple sclerosis
- Other:

- HIV infection
- Hypothyroidism, myxedema
- Rocky Mountain spotted fever
- Idiopathic

## *Genetics*

- 10% of patients have X-linked mutation of V2R (1)
- Polymorphisms in TPRV4 gene (2)

## *RISK FACTORS*

- Use of predisposing drugs
- Advanced age
- Postoperative status
- Institutionalization

## *GENERAL PREVENTION*

- Search for cause, if unknown.
- Reduce/change medications, if drug-induced.
- Lifelong restriction of fluid intake

## *COMMONLY ASSOCIATED CONDITIONS*

See ÒEtiology.Ó

## **DIAGNOSIS**

### **HISTORY**

Symptoms:

- Fatigue
- Anorexia
- Nausea
- Vomiting
- Diarrhea

- Headaches
- Unsteady gait
- Falls
- Myalgias/weakness
- Increased thirst
- Confusion
- Seizures, coma

## *PHYSICAL EXAM*

- Euvolemic state
- Mild/moderate hyponatremia (serum Na 125 to 135 mEq/L)
  - Slow cognition and reaction times
  - Hyporeflexia
  - Ataxia
- Severe hyponatremia (serum Na <125 mEq/L) (3)
- Altered mental status
- Lethargy
- Seizures
- Psychosis
- Coma
- Death

## *DIFFERENTIAL DIAGNOSIS*

- Intravascular volume depletion and thiazide-induced
- Appropriate ADH secretion secondary to decreased effective arterial blood volume (e.g., congestive heart failure [CHF], nephrotic syndrome, liver cirrhosis)
- Low solute intake hyponatremia
  - Tea and toast diet
  - Beer potomania
- Psychogenic polydipsia

- Intake usually >10 L/day
- Diuresis occurs when intake is stopped.
- Endocrinopathies
  - Addison disease
  - Hypothyroidism
- Translocational hyponatremia: caused by hyperglycemia, mannitol, sucrose, glycine
- Pseudohyponatremia
  - Lab artifact caused by hyperlipidemia, paraproteinemias, administration of IVIG
  - Labs using flame photometry or indirect potentiometry susceptible
- Postoperative complications:
  - Caused by nonosmotic release of ADH, probably mediated by pain afferents
  - ADH stimulated by pain, nausea, vomiting, and hypotension
- Cerebral salt-wasting syndrome (hyponatremia, extracellular fluid depletion, CNS insult)

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Serum Na level: low
- Serum urea level: normal to low
- Serum osmolality: low
- Urine osmolality: high; urine osmolality >100 mOsm/kg H<sub>2</sub>O (4)
- Urine Na concentration: high; urine Na >30 mEq/L (4)
- Fractional excretion of Na >0.5 % (4)
- Serum ADH level: high (not clinically useful)
- Not usually required for diagnosis but to assess for other concerns:
  - Serum uric acid
  - Serum glucose; creatinine
  - Thyroid function
  - Morning cortisol

## TREATMENT

### GENERAL MEASURES

- Treatment of the underlying cause is essential.
- Requires frequent monitoring (see Patient Monitoring)
- Fluid restriction (<1,000 mL/day) is the main form of treatment (5)[C].
- Mildly symptomatic (serum Na >125 mEq/L [ $>125$  mmol/L]): Restrict fluid to <1,000 mL/day.

P.1009

- Acute (<48 hours duration) or symptomatic (altered mental status, seizure, coma)
  - Hypertonic saline (3% normal saline) bolus
  - Diuresis with loop diuretics
  - Restrict oral free water intake.
  - Increase oral solute intake.
  - Calculate serum Na deficit (mEq Na deficit = [desired Na - actual Na]  $\times$  0.5  $\times$  body weight [kg]).
  - Increase serum Na slowly with hypertonic saline by 4 to 6 mEq/L over 4 to 6 hours (not to exceed 10 mEq/L in a 24-hour period) (3,6,7).

### MEDICATION

- If severe or neurological symptoms: IV 3% sodium chloride to increase serum Na cautiously (8)[B]:
  - If serum Na <120 mEq/L or severe neurologic symptoms; consider bolus of hypertonic saline to increase serum Na by 4 to 6 mEq/L over the first 4 to 6 hours.
- Sodium chloride (NaCl) oral tablets
- Oral urea is an option, but limited due to bitter taste.
- Loop diuretics: furosemide (Lasix) + KCl replacement
- Vasopressin-2 receptor antagonist (the vaptans: tolvaptan, conivaptan) (8),(9)[C]
  - Good efficacy and safety profiles in the treatment of moderate hyponatremia due to SIADH
  - Liberal fluid intake encouraged.
  - Must be initiated in hospital setting.

- Cost may limit long-term use.
- Avoid tolvaptan in patients with liver disease.
- Demeclocycline (second line) (10)[C]
  - Blocks ADH at renal tubule; produces nephrogenic diabetes insipidus
  - Dosage for long-term management: 300 to 600 mg PO BID
  - Onset of action within 1 week; therefore, not best for acute management.
- Contraindications: Avoid fluids in CHF, nephrotic syndrome, or cirrhosis. Avoid tolvaptan in patients with cirrhosis due to possible liver injury.
- Precautions: Overly rapid correction ( $>10$  mEq/L/day) can increase risk for osmotic demyelination syndrome:
  - Permanent CNS damage in pons leading to quadriplegia and pseudobulbar palsy.
  - Increased risk in women, alcoholics, malnutrition, hypoxia, and hypokalemia

## **ALERT**

Increase Na levels slowly, no more than 10 mEq/L/24 hr, to prevent complications such as central pontine myelinolysis (CPM) (3)[C].

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Careful continuous clinical and laboratory monitoring of hyponatremic state during acute phase:
  - Hourly urine output
  - Urine Na
  - Serum Na and potassium (K) every 4 to 6 hours if moderate/severe, then daily once stable
  - Goal sodium increase is  $<10$  mEq/L in first 24-hour period, then 8 mEq/L in subsequent 24-hour periods until Na reaches 130 mEq/L (3)[C].
- Chronic management: Treat underlying cause; continue fluid restriction and NaCl tablets as needed.

## DIET

Increase protein/solute intake and decrease water intake.

## PATIENT EDUCATION

Diet and fluid restrictions

## PROGNOSIS

- Depends on underlying cause; in general, higher morbidity and mortality in hospitalized patients with hyponatremia
- If symptomatic (seizure, coma): high mortality due to cerebral edema if serum Na <120 mEq/L (<120 mmol/L)

## COMPLICATIONS

- Falls and hip fractures
- Cerebral edema (see "Prognosis")
- Osmotic demyelination with overcorrection (see "Treatment" precautions): central pontine and extrapontine irreversible myelinolysis (6,11)
- Chronic hyponatremia
- Chronic hyponatremia is associated with osteoporosis (12)[C].

## ICD10

E22.2 Syndrome of inappropriate secretion of antidiuretic hormone

# Clinical Pearls

## &NA;

- Treatment of the underlying cause is a key. Review all medications for potential culprits.
- Consultation is recommended in moderate to severe hyponatremia or if hypertonic saline indicated.
- Fluid restriction is the mainstay of treatment in SIADH. Fluid restriction fails to correct hyponatremia and Na wasting in salt-losing renal disease.
- Cerebral salt wasting is a controversial disease entity and is similar to SIADH. However, patients with SIADH are euvoletic, whereas patients with cerebral salt wasting are hypovolemic. The only real way to establish the diagnosis is through fluid restriction. Serum urate and fractional excretion of urate will be corrected with fluid restriction in SIADH, but will not correct in cerebral salt wasting.
- CPM is a cerebral demyelination syndrome that causes quadriplegia, pseudobulbar palsy, seizures, coma, and death. It is caused by an overly rapid rate of Na correction.
- Safe correction of hyponatremia is important. Online calculators are available: [www.medcalc.com/sodium.html](http://www.medcalc.com/sodium.html).

# Syphilis

Melissa Badowski, PharmD

Mahesh C. Patel, MD

## BASICS

### DESCRIPTION

- A chronic, systemic infectious disease caused by *Treponema pallidum*
- Transmitted sexually, vertically (maternal-fetal) by direct contact with an active lesion, and via blood transfusions
- Untreated disease includes four overlapping stages.
  - Primary: single (usually) painless chancre at point of entry; appears in 10 to 90 days; chancre heals without treatment in 3 to 6 weeks
  - Secondary: appears 2 to 8 weeks after primary chancre. Nonpruritic rash on palms or soles of feet, mucous membrane lesions, headache, fever, lymphadenopathy, alopecia
  - Latent: seroreactive without evidence of disease
    - Early latent: acquired within the last year
    - Late latent: exposure >12 months prior to diagnosis
  - Tertiary (late): Serology may be negative (fluorescent treponemal antibody absorption [FTA-ABS] test typically positive).
    - Gumma, cardiovascular, and late neurosyphilis; may be fatal
  - Neurosyphilis: *any* type of CNS involvement; can occur at *any* stage
    - Psychosis, delirium, dementia
- Syphilis can affect nearly every organ/tissue in the body leading to moniker "the great imitator."

### Pediatric Considerations

In noncongenital cases, consider child abuse.

## *Pregnancy Considerations*

- All pregnant patients should be screened with VDRL or rapid plasma reagin (RPR) test early in pregnancy. If high exposure risk, repeat at 28 weeks and at delivery (1,2)[A].
- The same nontreponemal test used for initial screening should be used for follow-up (1,2)[A].

## *EPIDEMIOLOGY*

### *Incidence*

- Syphilis rate decreased until 2000; has increased (primarily in men) since then (3)[A].
- In 2013: 5.3/100,000. Highest for men aged 25 to 29 years and women aged 20 to 24 years (3)[A]
  - Men: 9.8/100,000
  - Women: 0.9/100,000
- Congenital: 8.7 cases/100,000 live births (4)[A]
- Race/ethnicity (3)[A]
  - Male (per 100,000 population)
    - White, non-Hispanic: 5.4
    - Black, non-Hispanic: 27.9
    - Hispanic: 11.6
    - Asian/Pacific Islander: 4.6
    - American Indian/Alaska native: 4.7
  - Female (per 100,000 population)
    - White, non-Hispanic: 0.3
    - Black, non-Hispanic: 4.0
    - Hispanic: 0.8
    - Asian/Pacific Islander: 0.2
    - American Indian/Alaska native: 1.0

### *Prevalence*

- Predominant sex: male (91%) > female (9%) (3)[A]

- Greatest increase in men having sex with men (MSM) (3)[A]

## ETIOLOGY AND PATHOPHYSIOLOGY

*T. pallidum* subspecies *pallidum*, spirochete: can enter through intact mucous membranes or breaks in skin. Highly infectious; exposure to as few as 60 spirochetes is associated with ~50% chance of infection

## RISK FACTORS

MSM, multiple sexual partners, exposure to infected body fluids, IV drug use, transplacental transmission, adult inmates, high-risk sexual behavior, HIV positive

## GENERAL PREVENTION

Education regarding safe sex; condoms reduce but do not eliminate transmission (5)[A]

## COMMONLY ASSOCIATED CONDITIONS

HIV infection, hepatitis B, other STIs

## DIAGNOSIS

### HISTORY

- Previous sexual contact with partner with known infection or high-risk sexual behavior
- Genital lesions (chancre—primary syphilis)
- Rash, alopecia, malaise, headache, anorexia, nausea, fatigue (secondary syphilis)
- Mental status changes (tertiary syphilis)

## PHYSICAL EXAM

Signs/symptoms depend on stage

- Primary: single (occasionally multiple), usually painless ulcer (chancre) in groin or at other point of entry. Regional adenopathy.
- Secondary
  - Rash: skin/mucous membranes
    - Rough, red-brown macules, usually on palms and soles
    - May appear with chancre or after it has healed

- Condyloma lata
- Alopecia
- Nonspecific symptoms: fever, adenopathy, malaise, headache, hair loss
- Tertiary
  - Focal neurologic findings (hearing loss, visual loss)
  - Gummas (skin, mucous membranes, other organ systems)

## ***DIFFERENTIAL DIAGNOSIS***

- Primary: chancroid, lymphogranuloma venereum, granuloma inguinale, condyloma acuminata, herpes simplex, Behçet syndrome, trauma, carcinoma, mycotic infection, lichen planus, psoriasis, fungal infection
- Secondary: pityriasis rosea, drug eruption, psoriasis, lichen planus, viral exanthema, Stevens-Johnson syndrome
- Positive serology, asymptomatic: previously treated syphilis/other spirochetal disease (yaws, pinta)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Dark-field microscopy demonstrating *T. pallidum* spirochetes in lesion exudate/tissue biopsy: gold standard but difficult and not very sensitive (6)[A]
- Nontreponemal tests (VDRL/RPR) (3,6)[A]
  - Primary screening test: positive within 7 days of exposure
  - Nonspecific, false-positive results common; must confirm diagnosis with treponemal tests
  - Positive test should be quantified and titers followed regularly after treatment.
    - Titers usually correlate with disease activity; 4-fold change is clinically significant.
    - Titers decrease with time/treatment; following adequate treatment for primary/secondary disease, a 4-fold decline is typically seen after 6 to 12 months.
    - Absence of a 4-fold decline suggests potential treatment failure.
    - ÷15% of appropriately treated patients do not have a 4-fold decline in titer 12 months after treatment. Management is unclear, repeat HIV testing and/or CSF examination and continue to follow titers.

- With appropriate treatment, titers should become negative (see serofast reaction).
- Titers of patients treated in latent stages decline more gradually.
- Prozone phenomenon: negative results from high titers of antibody; test with diluted serum
- Serofast reaction: persistently positive results years after successful treatment; new infection diagnosed by 4-fold rise in titer
- Conditions that may alter treponemal testing (all stages of syphilis can have a false-negative RPR result, especially in primary syphilis)
  - Pregnancy, autoimmune disease, mononucleosis, malaria, leprosy, viral pneumonia, cardiolipin antigens, injection drug use, acute febrile illness, HIV infection; elderly can have false-positive results.
- Treponemal tests (*confirmatory test after positive nontreponemal screening test*): FTA-ABS, TP-PA (*T. pallidum* particle agglutination) (6)[A]:
  - Confirmatory test; not used for screening
  - Usually positive for life after treatment
  - Titers of no benefit
  - 15-25% of patients treated during primary stage revert to serologic nonreactivity after 2 to 3 years.
- Lumbar puncture indicated for (6)[A]:
  - Neurologic, ocular, or auditory manifestations
  - Some experts advise in all secondary and early latent cases—even without neurologic symptoms
  - HIV-positive patients with late latent/latent of unknown duration
  - In patients with late latent/latent of unknown duration if nonpenicillin therapy planned
  - In treatment failures
  - If other evidence of active tertiary syphilis is present (e.g., aortitis, gumma, iritis)
  - In children to rule out neurosyphilis
  - VDRL, not RPR, used on CSF; may be negative in neurosyphilis; highly specific but insensitive
  - Send CSF for protein, glucose, and cell count.
  - Monitor resolution by cell count at 6 months along with serologies (see Patient

Monitoring).

- Negative FTA-ABS or microhemagglutination (MHA)-TP on CSF excludes neurosyphilis (highly sensitive).
- Positive FTA-ABS or MHA-TP on CSF is not diagnostic because of high false-positive rate.
- Traumatic tap, tuberculosis (TB), pyogenic/aseptic meningitis can all result in false-positive VDRL.

P.1011

## TREATMENT

### GENERAL MEASURES

- Advise patients to avoid intercourse until treatment is complete, and notify partners (6)[A].
- Test for HIV (3,6)[A].
- Management of sexual contacts (6)[A]
  - Presumptively treat partners exposed within 90 days of diagnosis.
  - Treat those exposed >90 days before diagnosis presumptively if serologic results are not available immediately and follow-up is uncertain.
  - Presumptively treat those exposed to a patient diagnosed with syphilis of unknown duration who have high treponemal titers (>1:32).
  - Long-term sex partners of patients with latent infection should be evaluated clinically and serologically and treated accordingly.

### MEDICATION

#### ALERT

Bicillin L-A should be used instead of Bicillin C-R (combination benzathine-procaine penicillin) when penicillin G benzathine is indicated.

#### First Line

Parenteral penicillin G is the drug of choice. The particular formulation is determined by the disease stage and clinical presentation.

- Primary, secondary, and early latent <1 year (6)[A]
  - Benzathine penicillin G 2.4 million U IM × 1 dose

- Penicillin-allergic patients: doxycycline 100 mg PO BID for 2 weeks, or tetracycline 500 mg PO QID for 2 weeks, or ceftriaxone 1 to 2 g IM or IV daily for 10 to 14 days
    - Azithromycin 2 g PO × 1 dose (early syphilis only; should not be used in HIV, MSM, or pregnancy)
    - Resistance and treatment failures have been noted in several U.S. regions.
- Late latent/latent of unknown duration and tertiary without evidence of neurosyphilis (6)[A]
  - Benzathine penicillin G 2.4 million U IM weekly × 3 doses
  - Penicillin-allergic patients: Attempt desensitization and treatment with penicillin or doxycycline 100 mg PO 2 BID for 28 days, or tetracycline 500 mg PO QID for 28 days; compliance may be an issue.
- Ocular or neurosyphilis (6)[A]
  - Aqueous crystalline penicillin G 3 to 4 million U IV q4h as continuous infusion for 10 to 14 days
  - Alternative: Procaine penicillin G 2.4 million U IM daily in conjunction with probenecid 500 mg PO QID for 10 to 14 days (if compliance can be ensured)
  - Penicillin-allergic patients: Attempt desensitization and treat with penicillin; ceftriaxone 2 g/day IM or IV for 10 to 14 days.
  - If late latent, latent of unknown duration, or tertiary in addition to neurosyphilis, consider also treating as recommended for late latent after completion of neurosyphilis treatment.
- Congenital (6)[A]
  - Aqueous crystalline penicillin G 50,000 U/kg/dose IV q12h for the first 7 days of life and q8h thereafter for a total of 10 days, or procaine penicillin G 50,000 U/kg/dose IM daily for 10 days
  - If negative CSF serologies, normal physical exam, and titer: Maternal titer, then 50,000 U/kg benzathine penicillin G IM in single dose is also an alternative.
  - If >1 day of drug is missed, restart course.
  - Children (after newborn period): aqueous crystalline penicillin G 50,000 U/kg/dose IV q4-6h for 10 days; late latent, 50,000 U/kg IM as 3 doses at 1-week intervals
  - For contacts without symptoms: Treat as primary after serologies are obtained.
  - HIV-infected and pregnant patients may show poor response to recommended IM doses. Use IV therapy for all treatment failures in these patients.
  - Do not give benzathine or procaine penicillins IV.

- Children (after newborn period) (6)[A]: aqueous crystalline penicillin G 50,000 U/kg/dose IV q4-6h for 10 days; late latent, 50,000 U/kg IM as 3 doses at 1-week intervals
- Pregnancy (6)[A]
  - Treatment is the same as for nonpregnant patients
  - Some recommend 2nd dose of 2.4 million units benzathine penicillin G 1 week after initial dose in 3rd trimester or with primary, secondary, or early latent syphilis.
  - Penicillin sensitivity: No proven alternatives to penicillin available for treatment during pregnancy.
  - Penicillin-allergic patients: Desensitize and treat with penicillin.
  - HIV-infected pregnant patients may show poor response to recommended IM doses. Use IV therapy for all treatment failures in these patients.
- Treat contacts without symptoms as primary after serologies.
- History of penicillin allergy:
  - Confirmed IgE-mediated reaction: desensitization
  - Questionable history of IgE-mediated hypersensitivity: penicillin skin testing *if* major and minor penicillin determinants available
- Precautions (6)[A]
  - HIV-infected and pregnant patients may show poor response to recommended IM doses. Use IV therapy for all treatment failures in these patients.
  - Do not give benzathine or procaine penicillins IV.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- Clinical and serologic evaluation between 6 and 12 months after treatment; if >1 year duration, check at 24 months (6)[A].
- In HIV-infected persons, clinical and serologic evaluation at 3, 6, 9, 12, and 24 months after therapy (6)[A]

### *Patient Monitoring*

- Use VDRL or RPR test to monitor therapy: 4-fold rise (two dilutions) in titer indicates new

infection, whereas failure to decrease 4-fold (two dilutions) in 6 to 12 months may indicate treatment failure (although definitive criteria for cure not established); always use same test (preferably same lab) for initial screening (6)[A].

- Strongly consider retreatment for persistent clinical signs or recurrence, 4-fold rise in titers, or failure of initially high titer to decrease 4-fold by 6 to 12 months.
- Neurosyphilis: repeat lumbar puncture every 6 months to check for normalization of CSF cell count ( $\pm$  CSF-VDRL and protein evaluation) (6)[A]

## ***PATIENT EDUCATION***

No intimate contacts until 4-fold titer drop

## ***PROGNOSIS***

- Excellent in all cases except patients with late syphilis complications and with HIV infection
- Syphilis in HIV-infected patient
  - Treatment same as for HIV-negative patients
  - More often false-negative treponemal and nontreponemal tests or unusually high titers
  - Response to therapy less predictable
  - Early syphilis: increased risk of neurosyphilis and higher rates of treatment failure
  - Late neurosyphilis: harder to treat; can occur up to 20+ years after infection

## **COMPLICATIONS**

- Membranous glomerulonephritis
- Paroxysmal cold hemoglobinemia
- Meningitis and tabes dorsalis
- Cardiovascular aneurysms; valvular damage
- Irreversible organ damage
- Jarisch-Herxheimer reaction
  - Fever, chills, headache, myalgias, new rash
  - Common when starting treatment (of primary/secondary disease; less common with tertiary) owing to lysis of treponemes
  - Should not be confused with drug reaction
  - Managed with analgesics and antipyretics

## Codes

&NA;

## ICD10

- A53.9 Syphilis, unspecified
- A51.0 Primary genital syphilis
- A53.0 Latent syphilis, unspecified as early or late

# Clinical Pearls

**&NA;**

- Screen all HIV-positive patients and patients with high-risk sexual behaviors for syphilis.
- Penicillin remains the treatment of choice for syphilis.
- Syphilis rates are rising—particularly among MSM.

# Tarsal Tunnel Syndrome

Jeff Wang, MD, MPH

J. Herbert Stevenson, MD

## BASICS

### DESCRIPTION

A compression neuropathy of the posterior tibial nerve as it passes behind the medial malleolus and under the flexor retinaculum (lacinate ligament) in the medial ankle (the tarsal tunnel)

### *Pregnancy Considerations*

- Tarsal tunnel syndrome can occur during pregnancy, typically secondary to local compression caused by fluid retention and volume changes (1).
- Care is supportive. Most cases resolve after pregnancy.

### EPIDEMIOLOGY

- Women are slightly more affected than men (56%).
- All postpubescent ages are affected.

### ETIOLOGY AND PATHOPHYSIOLOGY

- The posterior tibial nerve passes through the tarsal tunnel, which is formed by three osseous structures—sustentaculum tali, medial calcaneus, and medial malleolus—covered by the lacinate ligament.
- Compression of the posterior tibial nerve within the tarsal tunnel results in decreased blood flow, ischemic damage, and resultant symptoms (1).
- Chronic compression can destroy endoneurial microvasculature, leading to edema and (eventually) fibrosis and demyelination (2).
- Increased pressure in the tarsal tunnel is caused by a variety of mechanical and biochemical mechanisms. The specific cause for compression is identifiable in only 60-80% of patients (1).
- Three general categories: trauma, space-occupying lesions, deformity (1)
  - Trauma including displaced fractures, deltoid ligament sprains, or tenosynovitis

- Varicosities
- Hindfoot varus or valgus
- Fibrosis of the perineurium
- Other causes:
  - Osseous prominences
  - Ganglia; lipoma; neurolemmoma
  - Inflammatory synovitis
  - Pigmented villonodular synovitis
  - Tarsal coalition
  - Accessory musculature
- In patients with systemic disease (e.g., diabetes), the "double crush" syndrome refers to the development of a second compression along the same nerve at a site of anatomic narrowing in patients with previous proximal nerve damage (3).
- Tarsal tunnel decompression may improve sensory impairment and restore protective sensation in diabetic peripheral neuropathies if there is nerve entrapment at the tarsal tunnel.

## *RISK FACTORS*

- Tarsal tunnel syndrome is associated with certain occupations and activities involving repetitive weight bearing on the foot and ankle (jogging, dancing).
- Other possible risk factors include (4):
  - Diabetes
  - Systemic inflammatory arthritis
  - Connective tissue disorders
  - Obesity
  - Varicosities
  - Heel varus or valgus
  - Bifurcation of the posterior tibial nerve into medial and lateral plantar nerves proximal to the tarsal tunnel

Tarsal tunnel syndrome is largely a clinical diagnosis, characterized by pain and paresthesias in a predictable distribution along the medial aspect of the ankle and plantar surface of the foot (1).

## **HISTORY**

- History of trauma (may be trivial) to the foot precipitating pain
- Pain behind medial malleolus radiating to the longitudinal arch and plantar aspect of foot including the heel
- Tightness, burning, tingling, and numbness (1)
- Pain usually worsens during standing or activity.
- Pain radiates proximally up the medial leg (Valleix phenomenon) in 33% of patients with severe compression.
- Some patients have substantial night pain (may be related to venostasis).
- Symptoms improve with rest, wearing loose footwear, and elevation.
- In advanced nerve compression, motor involvement may cause weakness, atrophy, and digital contractures of the intrinsic foot muscles (4).

## **ALERT**

Other systemic neuropathies (diabetes, alcoholism, HIV, drug reactions) present with similar symptoms.

## **PHYSICAL EXAM**

- Foot alignment
  - Examine for hindfoot varus or valgus deformity.
  - Exaggerating heel dorsiflexion, inversion, or eversion may reproduce symptoms by stretching or compressing the posterior tibial nerve.
- Palpate the tarsal tunnel and the course of the tibial nerve for tenderness and swelling.
- Tinel sign: Percussion over the the tibial nerve may reproduce paresthesias that radiate distally.
- Valleix sign: Percussion over the tibial nerve may produce paresthesias that radiate proximally.
- Cuff test: Inflating a pneumatic cuff engorges varicosities and reproduces symptoms.
- Compression test: Applying pressure to the tarsal tunnel for 60 seconds may reproduce symptoms.
- Sensory examination
  - The medial calcaneal nerve usually is spared, but numbness and altered sensation may be

present in the distribution of the medial or lateral plantar nerves.

- Vibratory sensation and two-point discrimination are decreased early in the disease process.
- Motor examination
  - Intrinsic foot muscle weakness (difficult to assess)
  - Rarely, weakness of toe plantar flexion may be present.
  - Atrophy of the abductor hallucis or abductor digiti minimi may be seen late in the disease process.

## *DIFFERENTIAL DIAGNOSIS*

- Peripheral neuropathies (diabetes, alcoholism, HIV, or drug related)
- Inflammatory arthritis (rheumatoid arthritis)
- Morton neuroma
- Metatarsalgia
- Subtalar joint arthritis
- Tibialis posterior tendinitis/dysfunction
- Plantar fasciitis
- Plantar callosities
- Peripheral vascular disease
- Lumbar radiculopathy
- Proximal injury or compression of the tibial branch of the sciatic nerve

## *DIAGNOSTIC TESTS & INTERPRETATION*

### **Initial Tests (lab, imaging)**

Routine lab tests help rule out other conditions that may mimic tarsal tunnel syndrome, including diabetic neuropathy, rheumatoid arthritis, thyroid dysfunction, or other systemic illnesses (5).

- Routine weight-bearing radiographs, followed by CT (if necessary) to assess for fracture or structural abnormality
- Consider evaluation of lumbar spine x-ray if double crush (injury to lumbar nerve results in compensatory injury to posterior tibial nerve) is suspected (5).
- MRI: helps assess the tarsal tunnel for soft tissue masses or other sources of nerve

compression before surgery (1)

- Ultrasound: Gaining importance and with several advantages over MRI (6); can assess for tenosynovitis, ganglia, varicose veins, or lipomas (1)

## *Pediatric Considerations*

MRI is recommended for evaluating pediatric tarsal tunnel syndrome to exclude neoplastic mass.

P.1013

## **Diagnostic Procedures/Other**

Electrodiagnostic studies

- Electromyography (EMG) of the intrinsic muscles of the foot can confirm the diagnosis of tarsal tunnel syndrome (7). A normal EMG does not exclude the diagnosis (false-negative rate is ÷ 10%) (1).
- Nerve conduction studies may reveal slowed conduction of the tibial nerve.
- Evaluate for proximal nerve compression, including a lumbar radiculopathy or a double crush phenomenon.

## **TREATMENT**

Conservative management is recommended, except for acute onset tarsal tunnel syndrome or in the setting of a known space-occupying lesion (excluding synovitis).

## *MEDICATION*

### **First Line**

- Analgesics and anti-inflammatory medications
- Local corticosteroid injection
- Medications that alter neurogenic pain (tricyclic antidepressants, antiepileptic drugs, nerve blockers)

## *ADDITIONAL THERAPIES*

- Rest/immobilization
- Taping and bracing
- Orthotics or shoe modification

- Physical therapy to strengthen the intrinsic and extrinsic muscles of the foot and to restore the medial longitudinal arch
- Other modalities (stretching, US, massage, icing)
- Compression stockings to decrease swelling
- Weight loss for obese patients

## ***SURGERY/OTHER PROCEDURES***

- Surgery is indicated (1,2,8).
  - If nonoperative measures fail following a 3- to 6-month trial
  - In the setting of acute tarsal tunnel syndrome
  - If a space-occupying lesion is identified
- The surgical outcome is dependent on technique and postoperative management. 50-95% of cases have good to excellent outcomes.
- At the time of surgery, assess focal swelling, scarring, or nerve abnormalities and look for a pathologic source of compression.
- Postoperative management includes:
  - Non-weight-bearing splint until incision heals (2 to 3 weeks), followed by progressively increased weight-bearing and range of motion exercises
  - Rest, ice, compression, elevation to limit swelling

## **ONGOING CARE**

### ***PATIENT EDUCATION***

- Discuss conservative and surgical options based on individual patient circumstance and preference.
- A decision about surgical intervention should be made with a clear understanding risks, benefits, and potential adverse outcomes.

### ***PROGNOSIS***

Surgery is most helpful for:

- Patients with a positive Tinel sign (3)[B]

- Young patients
- Short period between occurrence of symptoms and surgery <1 year (9)[B].
- Localized space-occupying lesion (1)
- No motor neuron involvement

## COMPLICATIONS

- The main adverse outcome is an unsuccessful surgical intervention characterized by lack of improvement or recurrence of symptoms (1).
- Causes for a failed tarsal tunnel release include (10):
  - Incorrect diagnosis
  - Incomplete release
  - Adhesive neuritis (external scar formation)
  - Intraneural damage (systemic disease, direct nerve injury)
  - Failure to treat all sources of nerve compression in a double crush phenomenon
- Electrodiagnostic studies are rarely helpful in determining the cause of a failed tarsal tunnel release.
- Results with surgical revision are poorer than those for the primary surgical release.

Algorithm: Foot Pain

## Codes

&NA;

## ICD10

- G57.50 Tarsal tunnel syndrome, unspecified lower limb
- G57.51 Tarsal tunnel syndrome, right lower limb
- G57.52 Tarsal tunnel syndrome, left lower limb

## Clinical Pearls

### &NA;

- Tarsal tunnel syndrome typically presents with pain and tingling of the medial ankle and plantar foot.
- Tinel sign is the most sensitive and specific physical examination test for diagnosing tarsal tunnel.
- EMG cannot independently diagnose tarsal tunnel syndrome; it is used to confirm a clinical diagnosis.
- Conservative management is recommended, except for patients with an acute onset tarsal tunnel syndrome or known space-occupying lesion.

# Teething

Dana Nguyen, MD, FAAFP

Katrina E. Walters, MD, FAAFP, FM

## BASICS

### DESCRIPTION

- Teething is the eruption of the primary or deciduous teeth, which most children experience without difficulty. It is a natural, gradual, and predictable process, with normal variation among infants (1,2).
- Primary (deciduous) teeth
  - Primary tooth eruption usually begins at 5 to 7 months of age.
  - The order of primary tooth eruption and average age is the following:
    - Central mandibular incisors (5 to 7 months)
    - Central maxillary incisors (6 to 8 months)
    - Lateral mandibular incisors (7 to 10 months)
    - Lateral maxillary incisors (8 to 11 months)
    - Cuspids (16 to 20 months)
    - 1st molars (10 to 16 months)
    - 2nd molars (20 to 30 months)
  - Delayed eruption may be familial or due to systemic syndromes or nutritional deficiencies. Delayed eruption may also be seen with cleft palate and lower birth weight (3,4,5).
  - Tooth eruption in premature infants occurs according to postconceptual age rather than age since birth (chronologic age) (2).
  - Natal/neonatal teeth
    - Natal teeth (present at birth) occur in 1/2,000 neonates.
    - Neonatal teeth erupt in the 1st month of life.
    - Natal/neonatal teeth are most often prematurely erupted primary (deciduous) teeth but

may be supernumerary.

- 15-20% of cases are familial; also may be secondary to a syndrome or congenital anomalies of the head and neck.
- Natal/neonatal teeth may be loose, but most are the normal deciduous lower central incisors and can persist.
- Natal/neonatal teeth may be removed if there is an aspiration risk or if they cause trauma to the infant or to the mother (breastfeeding) (2).

## *EPIDEMIOLOGY*

### **Incidence**

Predominant age: birth to 3 years of age

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Teething symptoms are more common with eruption of the primary incisors (6).

### *Genetics*

Both premature and delayed tooth eruption may be familial. Primary failure of eruption has been linked to mutations of the *PTHR1* gene (5).

## *COMMONLY ASSOCIATED CONDITIONS*

Teething may be coincident with other common childhood conditions, causing local or systemic signs and symptoms (e.g., fever, GI disturbance, fussiness, drooling, rash, and sleep disturbance). No pattern of symptoms that distinguishes teething from any other cause. Other possible causes of systemic symptoms should be ruled out prior to attributing them to teething (7).

## **DIAGNOSIS**

### **HISTORY**

- Biting
- Drooling
- Rubbing of gingivae
- Sucking
- Irritability
- Wakefulness

- Ear rubbing
- Facial rash
- Decreased appetite for solid foods
- Loose stools
- Temperature elevation  $<38.3^{\circ}\text{C}$
- Many infants do not have any symptoms.
- Symptoms most often occur 4 days before eruption and resolve by 3 days after eruption and are more common in ages 4 to 24 months (6,8,9,10)[B].

## *PHYSICAL EXAM*

- Infants may have no signs or symptoms of teething, although symptoms are present in most children.
- Excessive drooling and chewing on fingers begins at 3 to 4 months of age. This is also the time that normal hand to mouth stimulation increases salivation.
- Discomfort may be observed more commonly with the eruption of the first tooth, the molars, and/or with the simultaneous eruption of multiple teeth (11)[B].
- Minor signs and symptoms of biting or chewing, drooling, irritability, facial rash, and low-grade fever ( $<101.9^{\circ}\text{F}$ ;  $38.9^{\circ}\text{C}$ ) have been reported in association with teething, although no evidence identifies specific signs/symptoms caused by teething (9)[B].
- Serious signs and symptoms (e.g., fever  $>101.9^{\circ}\text{F}$ ;  $38.9^{\circ}\text{C}$ , dehydration) are not caused by teething and warrant evaluation for organic disease (7)[A].
- A small red or white spot may appear over the swollen gingivae just prior to tooth eruption.
- Local inflammation, swelling, or hematoma (bluish swelling) can be found on the involved gingivae overlying the erupting tooth. Gingival irritation was present in 96% of infants in one study (11)[B].

## *DIFFERENTIAL DIAGNOSIS*

Herpetic gingivostomatitis: Infants with fever, irritability, sleeplessness, and difficulty feeding may have underlying infection caused by herpes simplex virus. Some infants with positive culture may not have evidence of inflammation or ulceration expected in gingivostomatitis.

## *DIAGNOSTIC TESTS & INTERPRETATION*

### **Initial Tests (lab, imaging)**

Radiographs can distinguish prematurely erupted primary teeth from supernumerary teeth.

## TREATMENT

### GENERAL MEASURES

- Education of parents regarding common symptoms of teething and management options resulted in decreased use of pharmacologic treatment and increased use of other methods such as rubbing the gums (12)[B].
- Prospective trials show the strongest effectiveness evidence supporting teething rings, followed by cuddle therapy, followed by rubbing the gums to reduce symptoms (13)[B].
- Provide the infant with a safe, one-piece teething ring, clean cloth, or pacifier for gumming.
- Apply pressure over involved swollen gingivae with a clean finger or piece of wet gauze.
- May use cool (but not frozen) fluids, cold teething rings, or cold vegetables such as a peeled cucumber
- Avoid the use of alcohol (historically rubbed on gingivae for an analgesic effect).
- Gingival hematomas that erupt appear as blue cysts. Most do not require medical intervention. Be sure there are no other signs of a bleeding disorder.
- Avoid the following:
  - Dipping a pacifier or teething ring in sugar or honey
  - Giving an infant a bottle in bed
  - Using fluid-filled teething rings (contents may leak)
  - Using frozen foods or teething rings (these could cause thermal damage to the tissues)
  - Tying a teething ring around infant's neck (14)[C]

### MEDICATION

#### First Line

- Initial treatment with medications is not recommended.
- For an infant with low-grade fever, irritability, and/or inflamed gingivae (where other comforting measures have not been of help); acetaminophen in proper doses (15 mg/kg/dose q4-6h PRN) can be used.

#### Second Line

#### ALERT

Over-the-counter preparations for teething, such as lidocaine (Xylocaine 2%), or benzocaine (Baby Ora-Gel, Num-Zit Gel, Num-Zit Liquid, Baby Anbesol) should be AVOIDED. Misuse, overuse, toxicity, and sensitivity have been reported.

- These are of questionable benefit because they are washed off quickly by saliva, and the benefit may be due in part to the pressure placed on the gingivae when applied.
  - FDA issued a warning about possible serious harm, to include death (15)[A].

P.1015

## *ISSUES FOR REFERRAL*

- Parents should establish a dental home for infants by 12 months of age. Dental caries remain the most prevalent infectious disease in children in the United States. Preventative care and anticipatory guidance offered in a dental home help prevent early childhood caries (16)[A].
- Other medical problems may delay tooth eruption. It is reasonable to refer a child who has not erupted a tooth by 18 months of age to a dentist, if he or she is not seeing one already (5)[C].

## *ADDITIONAL THERAPIES*

Infants who bite or chew while breastfeeding can be trained not to bite by withdrawing the child from the breast for a moment, and then resume. Resist urge to startle the infant.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Homeopathy is used to treat teething. Chamomilla is one reported treatment, but no efficacy or safety studies have been published (17)[C].

## *INPATIENT CONSIDERATIONS*

### **Admission Criteria/Initial Stabilization**

Outpatient

### **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

No restrictions

### *DIET*

Breastfeeding can continue during and after teething. Otherwise, no special diet required.

## **PATIENT EDUCATION**

- Parents should be cautioned not to misinterpret teething as the cause of any systemic manifestation. The health provider should be consulted for any systemic complaints.
- American Dental Association, Mouth Healthy Web site:  
<http://www.mouthhealthy.org/en/babies-and-kids/>
- Teething Tots: [http://kidshealth.org/parent/pregnancy\\_newborn/common/teething.html](http://kidshealth.org/parent/pregnancy_newborn/common/teething.html)

## **PROGNOSIS**

Normal progression through the teething process without illness

## **COMPLICATIONS**

Dental caries are a common childhood illness and can be prevented with fluoride use. Current guidelines recommend the following:

- Use of fluoridated toothpaste for all children beginning with first tooth eruption.
- Use of fluoride varnish every 3 to 6 months after first tooth eruption.
- Dietary fluoride supplements if fluoride is not present in the drinking water (18)[A]

## Codes

&NA;

### ICD10

K00.7 Teething syndrome

## Clinical Pearls

&NA;

- Parents and caregivers should follow the American Academy of Pediatrics' recommendations for treating teething pain.
  - Use a teething ring chilled in the refrigerator (not frozen).
  - Gently rub or massage the child's gums with your finger to relieve the symptoms.

- Topical pain relievers and medications that are rubbed on the gums are not necessary or even useful because they wash out of the baby's mouth within minutes, and they can be harmful.
- Teething may cause discomfort but does not cause significant fevers.
- Teething babies can still breastfeed. Babies can be taught not to bite, and breastfeeding may continue past 12 months of age without difficulty.

# Telogen Effluvium

Quratulanne H. Jan, MD

Arham K. Barakzai, MD

## BASICS

Diffuse hair loss or hair thinning; most often an acute self-limited process

### DESCRIPTION

Telogen effluvium (TE) is a transient condition in which there is a premature conversion of a significant proportion of anagen (growth phase) hairs into telogen (resting phase) hairs resulting in increased shedding of these resting hair follicles and the clinical appearance of moderate to severe hair thinning.

- Five proposed types of TE (1)
  - Immediate anagen release: a highly common form, lasting 3 to 4 weeks, in which follicles meant to remain in anagen phase enter telogen prematurely due to a signal, including high fever, drug induced, or stress
  - Delayed anagen release: occurs most often postpartum, in which a large group of hair follicles that have remained in the anagen phase for an extended period all together enter the telogen phase, resulting in hair loss
  - Short anagen: a somewhat speculative type, in which at least 50% of the hair follicles have an idiopathic shortening of the anagen phase, resulting in a corresponding doubling of the follicles in the telogen phase
  - Immediate telogen release: Normal resting club hairs remain within the hair follicle until an unknown signal causes their release, initiating the anagen stage to begin. In this type, the resting club hairs are prematurely released, ending the telogen phase abruptly and causing diffuse shedding.
  - Delayed telogen release: in this type, the presence of increased visible light, whether it be a seasonal or environmental change, is thought to end a prolonged telogen phase and initiate the anagen phase, resulting in diffuse shedding of hair follicles.

### EPIDEMIOLOGY

## Incidence

Second most common cause of alopecia

## Prevalence

Unknown

## ETIOLOGY AND PATHOPHYSIOLOGY

- The hair cycle consists of two predominant phases. The anagen (growth phase) and the telogen (resting phase), lasting  $\div$  3 years and 3 months, respectively. On the scalp,  $\div$  10-15% of hairs are in the telogen phase normally. Due to the presence of some types of external/internal stress, there may be an increase in the percentage of telogen hairs. As new anagen hairs emerge, these telogen hair follicles are forced out. The preceding event usually occurs 2 to 3 months prior to the appearance of hair loss.
- It is hypothesized that substance P plays a key role in the pathogenesis of TE through various mechanisms (2,3). Studies have been conducted on human hair follicles in vitro and mice hair follicles in vivo, which support this theory.
- Role of substance P includes the following (4):
  - Upregulation of substance P receptor, NK1, at the gene and protein level, leading to premature catagen development and hair growth inhibition
  - Upregulation of nerve growth factor (NGF) and subsequently its hair apoptosis-producing receptor, p75NTR
  - Downregulation of hair growth-promoting receptor, TrkA
  - Upregulation of major histocompatibility class (MHC) I and *&bgr;*<sub>2</sub>-microglobulin resulting in loss of hair follicle immune-privilege
  - Increase in tumor necrosis factor-*&agr;*; release by mast cells resulting in hair keratinocyte apoptosis
- Decreased cortisol levels in chronic stress states may also enhance the effects of substance P (5).

## RISK FACTORS

- Infection
- Trauma
- Major surgery
- Thyroid disorder

- Febrile illness
- Malignancy
- Allergic contact dermatitis (6)
- Iron deficiency anemia (7,8)
- Excess vitamin A (1)
- Protein-calorie restriction (1)
- End-stage liver or renal disease
- Hormonal changes (including pregnancy, delivery, and estrogen-containing medications) (1)
- Chronic stress
- Drug induced (*β*-blockers, anticonvulsants, antidepressants, anticoagulants, retinoids, ACE-inhibitors, etc.) (1)
- Immunizations

## DIAGNOSIS

### HISTORY

- Commonly, an inciting event 2 to 6 months previous
- Fear of becoming bald
- Patients often present with bags of hair to emphasize the severity of their hair loss.

### PHYSICAL EXAM

- Decreased density of hair on the scalp, most commonly involving the crown
- In rare cases of chronic TE, there is hair loss of eyebrows and pubic region.
- May be able to demonstrate diffuse shedding of hair when running fingers through scalp
- Shed hairs are telogen hairs, which have a small bulb of unpigmented or pigmented keratin on the root end.
- May affect nail growth, resulting in the appearance of Beau lines, which are transverse grooves on the nails of the hands and feet

### DIFFERENTIAL DIAGNOSIS

Hypothyroidism

- Hyperthyroidism
- Alopecia areata (diffuse pattern)
- Androgenetic alopecia
- Drug-induced alopecia
- Systemic lupus erythematosus
- Secondary syphilis
- Trichotillomania

---

P.1017

## *DIAGNOSTIC TESTS & INTERPRETATION*

Most often, TE is a clinical diagnosis of exclusion. Blood work may be collected primarily to rule out other possible causes of hair loss and/or to identify a possible cause for TE.

### *Initial Tests (lab, imaging)*

If indicated:

- CBC, ferritin
- TSH
- Creatinine
- Consider hepatic enzymes.
- Consider RPR/VDRL.

### *Diagnostic Procedures/Other*

- Hair pull test: unreliable; performed by gently pulling 25 to 30 hairs from various sites on a patient's scalp. Each pull should elicit <5 normal club hairs; increased quantity may indicate possibility of TE (1).
- Hair clip test: Performed by cutting 25 to 30 hairs from the patient's scalp and examining them under a microscope. A negative test (not indicative of TE) will demonstrate <10% of hair shafts of small diameter. A positive test will demonstrate >10% of hair shafts of small diameter (1).
- Trichogram: ÷ 50 hairs are plucked from the patient's scalp, and the number of telogen and anagen hairs present are counted. In TE, there will be >10% of hairs in the telogen phase.
- Scalp biopsy: rarely needed; it is recommended that several 4-mm punch biopsies be obtained,

all horizontally embedded to determine an accurate anagen-to-telogen ratio. Histologically, catagen-telogen hairs have numerous apoptotic cells in the outer sheath epithelium. > 12-15% of hair follicles in telogen phase is consistent with TE (1,9).

## TREATMENT

TE is a benign, self-limited process. Identify and correct underlying cause. Patient should be reassured that full hair growth will occur in ÷ 6 months to 1 year. No treatment is required.

## MEDICATION

- Minoxidil stimulates hair regrowth via arteriolar smooth muscle vasodilation; not effective in TE
- Oral zinc therapy: New medication that may have benefits for patients with TE through various mechanisms all essential to hair growth, including the following (10)[C]:
  - Cofactor for enzymes needed in nucleic acid and protein synthesis and cell division
  - Inhibition of the catagen phase by blocking certain enzymes involved in hair apoptosis
  - Involved in hair growth regulation via hedgehog signaling

## COMPLEMENTARY & ALTERNATIVE MEDICINE

*Nigella Sativa* (black cumin) essential oil has also been studied and may be beneficial (11).

## Codes

&NA;

### ICD10

L65.0 Telogen effluvium

## Clinical Pearls

## **&NA;**

- TE is a self-limited form of nonscarring alopecia; most often acute.
- TE is due to a premature conversion of a significant proportion of anagen (growth phase) hairs into telogen (resting phase) hairs, resulting in increased shedding of these resting hair follicles and the clinical appearance of moderate to severe hair thinning and loss when growth resumes.
- There are many potential causes of TE, both emotional and physiologic. Often it is hard to determine the etiology, but eliminating the stressor often is the key to resolving TE and stimulating new hair growth.
- No treatment is needed. Patient should be reassured that complete hair regrowth will occur in 6 months to 1 year.

# Temporomandibular Joint Disorder (TMD)

Benjamin N. Schneider, MD

Jessica Johnson, MD, MPH

## BASICS

### DESCRIPTION

- Syndrome characterized by
  - Pain and tenderness involving the muscles of mastications and surrounding tissues
  - Sound, pain, stiffness, or grating in the temporomandibular joint (TMJ) with movement
  - Limitation of mandibular movement with possible locking or dislocation
  - Recent research suggests that TMD is a complex disorder with multiple causes consistent with a biopsychosocial model of illness (1)[B].
- System(s) affected: musculoskeletal
- Synonym(s): TMJ syndrome; TMJ dysfunction; myofascial pain-dysfunction syndrome; bruxism; orofacial pain

### EPIDEMIOLOGY

#### Incidence

- Symptoms more common in ages 30 to 50 years
- Predominant sex: female > male (4:1)

#### Prevalence

- General prevalence is 6-12% in both adults and older children. Up to 1/2 the population has at least one sign or symptom of TMD, but most are not limited by symptoms, and < 1:4 seek medical or dental treatment.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Pathophysiology is multifactorial, involving anatomic, behavioral, emotional, and cognitive factors.

- The American Academy of Orofacial Pain categorizes TMD according to three anatomic origins of pain and the change in name from TMJ to TMD emphasizes that many patients suffer from muscular and not articular pain.
- Cranial bone disorder including the mandible
  - Congenital and developmental disorders
  - Acquired disorders (fracture, neoplasm)
- Articular disorders of the joint
  - Congenital disorders
  - Inflammatory disorders: synovitis, arthritides, capsulitis, ankyloses
  - Avascular necrosis (rare)
  - TMJ disk derangement, osteoarthritis
  - Hyper- or hypomobile TMJ
  - TMJ trauma: condylar fractures, dislocation
- Muscle disorders involving the muscles of mastication
  - Occlusomuscular dysfunction (bruxism)
  - Masticatory muscle spasm
  - Myositis
  - Myofibrosis
  - Poorly fitting oral devices (dentures, splints, etc.)
  - Contracture
  - Neoplasia

## *Genetics*

Research is ongoing in gene polymorphisms associated with TMD and other pain disorders. These include the catechol O-methyltransferase gene (COMT), which is thought to be associated with changes in pain responsiveness.

## **RISK FACTORS**

- Macrotrauma to the face, jaw, and neck, including cervical whiplash injuries and hyperextension of jaw

Rheumatologic and degenerative conditions involving the TMJ

- Psychosocial stress and poor adaptive capabilities
- Repetitive microtrauma from dental malocclusion, including inappropriate dental treatment.
- Link with bruxism and jaw/teeth clenching is inconsistent.

## **GENERAL PREVENTION**

- Elimination of tension-causing oral habits
- Reduction in overall muscle tension

## **COMMONLY ASSOCIATED CONDITIONS**

Craniomandibular disorders, somatization disorder, somatoform pain disorder, other chronic pain syndromes, fibromyalgia, juvenile idiopathic arthritis, tension headache, sleep disturbance, tobacco use

## **DIAGNOSIS**

- TMD is a clinical diagnosis, and localized pain is the unifying feature.
- Several research classification systems exist. Most share several of the history and physical findings listed below.

### **HISTORY**

- Facial and/or TMJ pain
- Locking/catching of jaw; decreased range of motion
- TMJ noises: clicking, grinding, popping
- Headache, earache, neck pain

## **PHYSICAL EXAM**

- Facial symmetry, muscle hypertrophy, intraoral exam
- Palpation of muscles of mastication may reproduce pain.
- Test jaw range of motion (opening, closing, lateral, protrusive) and masticatory muscle strength.
  - Maximal (pain-free) jaw opening with interincisal distance < 40 mm is suggestive of joint rather than muscle pathology if accompanied by other signs and symptoms (normal 35 to 55 mm).

- Deviation to the affected side is common.
- Muscle tenderness and restricted pain-free opening are most consistent distinguishing signs.
- There may be tenderness over the TMJ.
- Clicking or crepitus of jaw with opening

## *DIFFERENTIAL DIAGNOSIS*

- Condylar fracture/dislocation
- Trigeminal neuralgia
- Dental or periodontal conditions
- Neoplasm of the jaw, orofacial muscles, or salivary glands
- Acute, nondental infection: parotitis, sialadenitis, otitis, mastoiditis
- Jaw claudication: giant cell arteritis
- Migraine or tension type headache
- Ramsay-Hunt syndrome (zoster auricular syndrome)

## *DIAGNOSTIC TESTS & INTERPRETATION*

- There are no labs to rule in TMD.
- Blood work may be useful to rule out other conditions (CBC, CMP, ESR, CRP).

### *Initial Tests (lab, imaging)*

- TMD is a clinical diagnosis based primarily on history and physical exam.
- Often, a poor correlation is found between pain severity and pathologic changes seen in joint or muscle tissues. Consider the following for severe or treatment-resistant cases, with MR or CT more useful as part of surgical workup:
  - Panoramic dental radiographs are a good first-line screen.
  - CT scan allows fine detail of bony structures, preferred for trauma.
  - US: Effusion and findings correlate with MRI and subjective pain.
  - MRI: noninvasive study for disc position; more sensitive than US; can help determine need for surgical management

### *Diagnostic Procedures/Other*

- Local anesthetic nerve block can differentiate orofacial pain of articular versus muscular origins.
- Arthroscopy can be diagnostic for cartilage and bony pathology.

## *Test Interpretation*

Positive findings include:

- Condylar head displacement
- Anterior disc displacement
- Posterior capsulitis
- Loosening of disc and capsular attachments
- Chondroid metaplasia of disc leading to disc perforation and degeneration

## **TREATMENT**

Signs and symptoms will abate without intervention in most patients. 50% report improvement in 1 year and 85% by 3 years. With conservative therapy, symptoms resolve in 75% of cases within 3 months.

- Therapeutic exercises, especially if displacement is present, including formal physical therapy.
- Psychosocial interventions, including cognitivebehavioral therapy with or without biofeedback (2)[A]
- Behavior modification to eliminate tension-relieving oral habits (2)[A]
- Occlusal adjustment cannot be recommended for the management or prevention of TMD, as there is an absence of evidence from RCTs that occlusal adjustment treats or prevents TMD (3)[A].
- Insufficient evidence exists either for or against the use of stabilization splint therapy for the treatment of TMD (4)[A].

P.1019

- The American Dental Association recommends a "less is often best" stepwise approach and offers the following stepwise progression for therapy:
  - Eating softer foods
  - Avoiding chewing gum and nail biting
  - Modifying pain with heat or ice

- Relaxation techniques including meditation and biofeedback
- Exercises to strengthen jaw muscles
- Medications
- Night guards and orthotics

## *MEDICATION*

### **First Line**

- Acetaminophen
- Naproxen
- Topical methylsalicylate
- Gabapentin
- Ibuprofen, if osteoarthritis is suspected (5)[B].

### *Second Line*

- Muscle relaxants
- Tricyclic antidepressants, SSRIs, or SNRIs
- Botulinum neurotoxin
- Acupuncture
- Opiates should be reserved for perioperative or severe or recalcitrant cases (5)[B].
- Ineffective medications (5)[B]
  - The following medications when compared with placebo in RCTs were shown to be ineffective in improving pain and should not be used for the treatment of TMD:
    - Benzodiazepines
    - Topical capsaicin
    - Diclofenac
    - Celecoxib

## *ADDITIONAL THERAPIES*

### Joint and muscle injections

- There is very limited evidence to recommend for or against injections into or around the TMJ.

Proposed therapies include steroids, hyaluronic acid, local anesthetics, and, recently, botulinum toxin.

- Steroids given >3 times annually may accelerate degenerative changes.
- Injections into inferior space or double spaces have better effect than superior space injections alone.
- Recent studies suggest that botulinum toxin type A (Botox) injections may be successful in cases that have failed first-line pharmacologic therapy (6)[B].

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Glucosamine may be effective if pain is secondary to osteoarthritis of the TMJ (5)[B].
- Multiple electronic diagnostic and treatment modalities are currently marketed to patients; however, the scientific literature does not support the use of electronic diagnostic and treatment devices for TMD at this time.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Relax jaw by disengaging teeth.
- Avoid wide, uncontrolled opening, such as yawning.
- Stress management and behavior-modification counseling may be helpful.
- Be aware of any teeth-clenching or grinding habits.

### *Patient Monitoring*

- Ongoing assessment of clinical response to conservative therapies (NSAIDs, behavior modification, occlusal splints) is necessary.
- Surgical procedure (arthroplasty, joint replacement) to correct disc displacement or replace a damaged disc may be indicated only if the patient has not responded to conservative treatment.

### *DIET*

Soft diet to reduce chewing

### *PROGNOSIS*

With conservative therapy, symptoms resolve in 75% of cases within 3 months.

- Patients benefit most from a comprehensive treatment approach including the following:
  - Restoration of normal muscle function
  - Pain control
  - Stress management
  - Behavior modification

## COMPLICATIONS

- Secondary degenerative joint disease
- Chronic TMJ dislocation
- Loss of joint range of motion
- Depression and chronic pain syndromes

## Codes

&NA;

### ICD10

- M26.60 Temporomandibular joint disorder, unspecified
- M26.62 Arthralgia of temporomandibular joint
- M26.63 Articular disc disorder of temporomandibular joint

## Clinical Pearls

&NA;

- The condition called TMD actually designates a number of potential underlying joint and muscle conditions involving the jaw.
- Characteristics of all are pain and functional limitation.
- TMD is a clinical diagnosis with limited utility of imaging.

- Cognitive-behavioral therapy reduces pain, depression, and limitation of function.
- Exercises may improve function and pain.
- Evidence is lacking to support occlusion correction or splinting.
- Naproxen, gabapentin, topical methylsalicylate, glucosamine, amitriptyline, acupuncture, and botulinum toxin injections have some evidence of efficacy.

# Testicular Malignancies

Huy Tan Tran, MD, LCDR, MC, USN

Moses H. Cheng, MAJ, MC, USA

## BASICS

### DESCRIPTION

- Testicular cancer accounts for 1% of all cancers in men; it is the most common solid malignancy in men aged 15 to 34 years (1).
- An estimated 8,430 new cases were diagnosed, and an estimated 380 deaths occurred in the United States in 2015 (2).
- Treatment produces an overall 5-year survival of 95.3%; for African American patients, this 5-year survival rate is alarmingly lower but has improved from 86% to 90% (2).

### ETIOLOGY AND PATHOPHYSIOLOGY

95% of all malignant tumors arising in the testes are germ cell tumors (GCTs), which are subclassified as follows:

- Seminomatous GCTs: most common type overall
- Nonseminomatous GCTs (NSGCTs): These include embryonal cell carcinoma, choriocarcinoma, yolk sac tumor, teratomas, or often multiple cell types; these are more clinically aggressive tumors.

### RISK FACTORS

- Cryptorchidism is the most firmly established risk factor: Relative risk of testicular cancer in all patients with cryptorchidism is 3 to 8, with a lower relative risk of 2 to 3 in those undergoing orchiopexy by age 12 years; in patients with unilateral cryptorchidism, the relative risk of testicular cancer in the contralateral normally descended testis is negligible (3).
- Personal history of testicular cancer
- Use of muscle building supplements
- Positive family history for testicular cancer

- Testicular dysgenesis
- Klinefelter syndrome
- Caucasian race
- HIV infections

## GENERAL PREVENTION

No evidence that screening for testicular cancer is effective (4).

## DIAGNOSIS

### HISTORY

- A painless solid testicular mass is pathognomonic for testicular cancer.
- Clinical symptoms of epididymitis or orchitis that do not respond to treatment warrant further evaluation.
- Gynecomastia can be a rare systemic endocrine manifestation of testicular neoplasm.

### PHYSICAL EXAM

- Testicular exam: Palpate for size, consistency, and nodules; masses do not transilluminate; a firm, hard, or fixed area should be considered suspicious.
- Lymph node and abdominal exam
- Gynecomastia

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- $\alpha$ -Fetoprotein (AFP),  $\beta$ -human chorionic gonadotropin ( $\beta$ -hCG), lactate dehydrogenase (LDH), creatinine, chemistry profile, complete blood count, liver enzymes, chest x-ray (CXR), and testicular ultrasound (US)
- Tumor markers AFP,  $\beta$ -hCG, and LDH are used to assist with diagnosis, prognosis, assessing treatment outcome, and monitoring for relapse:
  - AFP
    - Produced by nonseminomatous testicular cancer and is therefore associated with this histologic type

- Those with a histologically pure testicular seminoma and an elevated AFP are assumed to possess an undetected focus of nonseminoma tumor.
- $\beta$ -hCG
  - May be associated with both seminomatous or nonseminomatous tumors
  - Hypogonadism and marijuana use may cause benign elevations of  $\beta$ -hCG.
- LDH is less specific than AFP.
- Testicular US is the initial study.
- If an intratesticular mass is identified, measure serum AFP, LDH, and  $\beta$ -hCG and order a CXR.
- CT scan of the abdomen/pelvis, positron emission tomography (PET) scan, MRI of the brain, and bone scan are used for staging and metastases evaluation as clinically indicated.

### *Diagnostic Procedures/Other*

- Radical inguinal orchiectomy is the primary procedure for diagnosis and treatment.
- Testicular biopsy may be rarely considered if a suspicious intratesticular abnormality is identified on US; however, testicular microcalcification on US without any other abnormality can simply be observed and does not demand a biopsy.
- For those with unilateral testicular cancer, contralateral testicular biopsy is not routinely performed but should be considered when there is a cryptorchid testis, marked testicular atrophy, or a suspicious US for intratesticular abnormalities.

### *Test Interpretation*

Clinical staging (5):

- Stage 0: carcinoma in situ
- Stage IA: tumor limited to testis and epididymis without vascular/lymphatic invasion; tumor may invade into the tunica albuginea but not the tunica vaginalis; normal serum tumor markers
- Stage IB: tumor limited to testis and epididymis with vascular/lymphatic invasion or tumor extending through tunica albuginea with involvement of tunica vaginalis; tumor invades the spermatic cord with or without vascular/lymphatic invasion; tumor invades the scrotum with or without vascular/lymphatic invasion; no lymph node involvement or distant metastasis; normal serum tumor markers
- Stage IS: any tumor with elevated serum tumor markers but no nodal involvement or

metastasis

- Stage IIA: any tumor with lymph node mass/masses <2 cm
- Stage IIB: any tumor with lymph node mass/masses 2 to 5 cm
- Stage IIC: any tumor with lymph node mass >5 cm
- Stage IIIA: any tumor/lymph node presence; with nonregional nodal or pulmonary metastasis; either serum tumor markers normal or with mild elevation
- Stage IIIB: any tumor/lymph node presence; no distant metastasis or nonregional nodal involvement or pulmonary metastasis; with moderately elevated serum tumor markers
- Stage IIIC: any tumor/lymph node presence; with or without any metastasis; with greatly elevated serum tumor markers

## ***DIFFERENTIAL DIAGNOSIS***

Epidermoid cyst, epididymitis, hernia, hydrocele, hematoma, lymphoma, orchitis, spermatocele, testicular torsion, varicocele

## **TREATMENT**

### ***GENERAL MEASURES***

- Seminoma: Specifics are noted in the National Comprehensive Cancer Network guidelines (1):
  - Stages IA, IB: Options may include surveillance (preferred) (for low tumor load malignancy, i.e., pT1-pT3), single-agent carboplatin, or radiotherapy (2)[A].
  - Stage IS: Repeat elevated serum tumor marker and abdominal/pelvic CT scan (2)[A].
  - Stage IIA: radiotherapy to include para-aortic and ipsilateral iliac lymph nodes (preferred) or primary chemotherapy (2)[A]
  - Stage IIB: primary chemotherapy (preferred) or radiotherapy in select nonbulky cases to include para-aortic and ipsilateral iliac lymph nodes (2)[A]
  - Stages IIC, III
    - Good risk (any primary site and no nonpulmonary visceral metastases and normal AFP with any  $\beta$ -hCG or LDH): primary etoposide and cisplatin (EP) or bleomycin, etoposide, and cisplatin (BEP) chemotherapy (1)
    - Intermediate risk (any primary site and nonpulmonary visceral metastases and normal AFP with any  $\beta$ -hCG or LDH): primary BEP chemotherapy (1)

- Nonseminoma: Tumors with both seminomatous and nonseminomatous histology are managed as nonseminomatous. See "National Comprehensive Cancer Network guidelines" (1):
    - Stage IA: nonseminomatous surveillance protocol (preferred) or nerve-sparing retroperitoneal lymph node dissection (RPLND) (2)[A]
    - Stage IB: nerve-sparing RPLND or primary BEP chemotherapy (2)[A]; for T2 only can enter nonseminomatous surveillance protocol (2)[B]
    - Stage IS: primary chemotherapy followed by response evaluation:
      - Complete response, negative tumor markers: nonseminomatous surveillance protocol (2)[A]
      - Partial response, negative tumor markers: surgical resection of all residual masses (2)[A]
      - Incomplete response: Consider second-line therapy (2)[A].
    - Stage IIA
      - Negative tumor markers: nerve-sparing RPLND (2)[A] or primary chemotherapy (2)[B]
      - Persistent marker elevation: primary chemotherapy followed by response evaluation
        - Complete response, negative tumor markers: nonseminomatous surveillance protocol (2)[A] or bilateral RPLND + / - nerve-sparing in select cases (2)[B]
        - Partial response, negative tumor markers: surgical resection of all residual masses (2)[A]
        - Incomplete response: Consider second-line therapy (2)[A].
    - Stage IIB
      - Negative tumor markers: primary chemotherapy or nerve-sparing RPLND in highly selected cases (2)[A]
- 
- Persistent marker elevation: primary chemotherapy followed by response evaluation
    - Complete response, negative tumor markers: nonseminomatous surveillance protocol (2)[A] or bilateral RPLND + / - nerve-sparing in selected cases (2)[B]
    - Partial response, negative tumor markers: surgical resection of all residual masses (2)[A]
    - Incomplete response: Consider second-line therapy (2)[A].
  - Stage IIC: primary chemotherapy followed by response evaluation as per stages IIA and IIB (2)[A]

- Stages IIIA, IIIB, and IIIC: primary chemotherapy depending on risk profile, which is based on tumor, metastases, and postorchiectomy serum tumor markers (2)[A]
- Brain metastases: primary chemotherapy + / - radiotherapy, + / - surgery, as clinically indicated

## *MEDICATION*

### **First Line**

Primary chemotherapy regimens for GCTs:

- EP: Etoposide 100 mg/m<sup>2</sup>/day IV on days 1 to 5, cisplatin 20 mg/m<sup>2</sup>/day IV on days 1 to 5; repeat every 21 days (1)[A].
- BEP: Etoposide 100 mg/m<sup>2</sup>/day IV on days 1 to 5, cisplatin 20 mg/m<sup>2</sup>/day IV on days 1 to 5; bleomycin 30 U/dose IV weekly on days 1, 8, and 15 or days 2, 9, and 16; repeat every 21 days (1)[A].
- VIP: Etoposide 75 mg/m<sup>2</sup>/day IV on days 1 to 5; mesna 120 mg/m<sup>2</sup> slow IV push before ifosfamide on day 1, then mesna 1,200 mg/m<sup>2</sup> IV continuous infusion on days 1 to 5; ifosfamide 1,200 mg/m<sup>2</sup>/day on days 1 to 5; cisplatin 20 mg/m<sup>2</sup> /day IV on days 1 to 5, repeat every 21 days (1)[A].

### *Second Line*

- These agents are considered in patients who do not respond to first-line therapy or those who experience a recurrence: carboplatin, cisplatin, etoposide, ifosfamide, mesna, paclitaxel, and vinblastine (1)[A].
- Gemcitabine, oxaliplatin, and paclitaxel are used in palliative chemotherapy regimens (1)[A].

## *ADDITIONAL THERAPIES*

Consider sperm banking before treatment that may compromise fertility; rarely covered by insurance.

## *SURGERY/OTHER PROCEDURES*

- Radical inguinal orchiectomy: primary treatment for testicular cancer for all patients; prosthesis can be inserted at this time.
- RPLND identifies nodal metastases and provides accurate pathologic staging of the retroperitoneum.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

- Pure seminoma: Specifics are noted in the National Comprehensive Cancer Network guidelines (1),(2)[A]:
  - Stages IA, IB: in general, H&P, optional tumor markers, every 3 to 6 months for 1 years, every 6 to 12 months for years 2 to 3, then annually for years 4 to 5; abdominal/pelvic CT at 3, 6 and 12 months then every 6 to 12 months for years 2 to 3, every 12 to 24 months for years 4 to 5; CXR, as clinically indicated; less frequent if adjuvant therapy is given
  - Stage IS: repeat elevated serum tumor marker and assess with abdominal/pelvic CT scan for evaluable disease
  - Stages IIA, IIB (select): in general, H&P, optional tumor markers every 3 months for year 1, every 6 months for years 2 to 5; abdominal/pelvic CT at 3 and 6 to 12 months, then annually for years 2 to 3, then as clinically indicated; CXR every 6 months for years 1 to 2
  - Stages IIB (select), IIC, and III: Check all serum tumor markers along with chest, abdominal, and pelvic CT:
    - Residual mass 0 to 3 cm and normal serum tumor markers: H&P, AFP, *&bgr*;-hCG, LDH, CXR every 2 months for year 1, every 3 months for year 2, every 6 months for years 3 to 4, then annually; abdominal/pelvic CT scan at 3 to 6 months then as clinically indicated, PET scans as clinically indicated
    - Residual mass >3 cm and normal serum tumor markers: PET scan 6 weeks after chemotherapy:
      - Negative PET scan: abdominal/pelvic CT scans every 6 months for year 1, then annually for 5 years
      - Positive PET scan: Consider RPLND or second-line chemotherapy or radiotherapy
  - Any recurrence: Treat according to extent of disease at relapse.
- Nonseminoma: Specifics are noted in the National Comprehensive Cancer Network guidelines (1):
  - Stages IA and IB on surveillance only: H&P, AFP, *&bgr*;-hCG, LDH, every 2 months for year 1, every 3 months for year 2, every 4 to 6 months for year 3, every 6 months for year 4, annually thereafter; CXR and abdominal/pelvic CT depending on IA or IB
  - Follow-up after complete response to chemotherapy and RPLND in general: H&P, AFP,

*β*-hCG, LDH every 2 to 3 months for years 1 to 2, every 6 months for years 3 to 5, annually thereafter; abdominal/pelvic CT every 6 months for year 1, annually for year 2, as clinically indicated thereafter

- Follow-up after RPLND only: H&P, AFP, *β*-hCG, LDH, CXR every 2 months for year 1, every 3 months for year 2, every 4 months for year 3, every 6 months for year 4, annually thereafter; abdominal/pelvic CT at 3 to 4 months and, as clinically indicated, thereafter; CXR every 2 to 4 months year 1, 3 to 6 months year 2, annually thereafter

## PROGNOSIS

>90% of patients diagnosed are cured, including 70-80% with advanced tumors (1).

## COMPLICATIONS

- Surgical: hematoma, hemorrhage, infection, and infertility
- Radiotherapy: radiation enteritis and infertility
- Late complications (6):
  - Cardiovascular toxicity and second malignancies each have a 25-year risk of about 16% in those treated with chemotherapy and/or radiotherapy.
  - Risk for secondary malignancies remains increased for at least 35 years after treatment.
  - Increased incidence of metabolic syndrome occurs and is likely associated with lower testosterone levels.
  - Other late complications associated with chemotherapy, depending on the regimen, include chronic neurotoxicity, ototoxicity, renal function impairment, and pulmonary fibrosis.
- The incidence of late relapse in treated testicular cancer is now estimated to be 2-6%; the time to late relapse ranges from 2 to 32 years, with a median of 6 years (6).

## Codes

&NA;

### ICD10

- C62.90 Malignant neoplasm of unspecified testis, unspecified descended or undescended
- C62.00 Malignant neoplasm of unspecified undescended testis
- C62.10 Malignant neoplasm of unspecified descended testis

## Clinical Pearls

**&NA;**

- Testicular cancer is the most common solid organ tumor in men aged 15 to 34 years.
- Testicular US is initial imaging of choice for testicular pathology.
- Radical inguinal orchiectomy is used for both diagnosis and treatment, with possible radiotherapy or chemotherapy as adjuvant treatment.
- 96% overall survival at 10 years after diagnosis and treatment

# Testicular Torsion

Jonathan Green, MD

Michael P. Hirsh, MD

## BASICS

### DESCRIPTION

- Twisting of testis and spermatic cord, resulting in acute ischemia and loss of testis if unrecognized.
  - Intravaginal torsion: occurs within tunica vaginalis, only involves testis and spermatic cord
  - Extravaginal torsion: involves twisting of testis, cord, and processus vaginalis as a unit. Typically seen in neonates
- System(s) affected: reproductive

### Geriatric Considerations

Very rare in this age group

### Pediatric Considerations

Peak incidence is at 14 years of age (1)

### EPIDEMIOLOGY

#### Incidence

- ÷ 1/4,000 males before age 25 years
- Predominant age
  - Occurs from newborn period to 7th decade of life
  - 65% of cases occur in 2nd decade, with peak at age 14 years (1).
  - 2nd peak in neonates (in utero torsion usually occurs around week 32 of gestation) (1)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Twisting of spermatic cord causes venous obstruction, edema of testis, and arterial occlusion.

- ÖBell clapperÓ deformity is most common anatomic anomaly predisposing to intravaginal torsion.
  - High insertion of the tunica vaginalis on the spermatic cord, results in increased testicular mobility within tunica vaginalis (2)
  - Bilateral in ÷ 80% of patients (1,2)
- No clear anatomic defect is associated with extravaginal testicular torsion.
  - In neonates, the tunica vaginalis is not yet well attached to scrotal wall, allowing torsion of entire testis including tunica vaginalis (1).
- Usually spontaneous and idiopathic (1)
- 20% of patients have a history of trauma.
- 1/3 have had prior episodic testicular pain.
- Contraction of cremasteric muscle or dartos may play a role and is stimulated by trauma, exercise, cold, and sexual stimulation.
- Increased incidence may be due to increasing weight and size of testis during pubertal development.
- Possible alterations in testosterone levels during nocturnal sex response cycle; possible elevated testosterone levels in neonates (1)
- Testis must have inadequate, incomplete, or absent fixation within scrotum (1,2).
- Torsion may occur in either clockwise or counterclockwise direction (3).

## *Genetics*

- Unknown
- Familial testicular torsion, although previously rarely reported, may involve as many as 10% of patients (4).

## *RISK FACTORS*

- May be more common in winter
- Paraplegia
- Previous contralateral testicular torsion

# DIAGNOSIS

## HISTORY

- Acute onset of pain, often during period of inactivity.
- Onset of pain usually sudden but may start gradually with subsequent increase in severity (1,2,3).
- Nausea and vomiting are common.
  - Presence may increase the likelihood of testicular torsion versus other differential diagnoses (1,2,5).
- Prior history of multiple episodes of testicular pain with spontaneous resolution in an episodic crescendo pattern may indicate intermittent testicular torsion (6).

## PHYSICAL EXAM

- Scrotum is enlarged, red, edematous, and painful (1,2).
- Testicle is swollen and exquisitely tender (1,2).
- Testis may be high in scrotum with a transverse lie.
- Absent cremasteric reflex (1,2,3)

## DIFFERENTIAL DIAGNOSIS

- Torsion appendix testis (this may account for 35-67% of acute scrotal pain cases in children) (2)
- Epididymitis (8-18% of acute scrotal pain cases) (2)
- Orchitis
- Incarcerated or strangulated inguinal hernia
- Acute hydrocele
- Traumatic hematoma
- Idiopathic scrotal edema
- Acute varicocele
- Epididymal hypertension (venous congestion of testicle or prostate due to sexual arousal that does not end in orgasm)
- Testicular tumor
- Henoch-Schönlein purpura

- Scrotal abscess
- Leukemic infiltrate

## **DIAGNOSTIC TESTS & INTERPRETATION**

- Doppler US may confirm testicular swelling, but is diagnostic by demonstrating lack of blood flow to the testicle; positive predictive value (PPV) of 89.4% (5,7)[B].
- In boys with intermittent, recurrent testicular torsion, both Doppler US and radionuclide scintigraphy findings will be normal (7)[B].

### *Diagnostic Procedures/Other*

- Doppler US flow detection demonstrates absent or reduced blood flow with torsion and increased flow with inflammatory process (reliable only in first 12 hours) (7)[B].
- Radionuclide testicular scintigraphy with technetium-99m pertechnetate demonstrates absent/decreased vascularity in torsion and increased vascularity with inflammatory processes (including torsion of appendix testes) (8)[C].

### *Test Interpretation*

- Venous thrombosis
- Tissue edema and necrosis
- Arterial thrombosis
- Decreased Doppler flow also seen in hydrocele, abscess, hematoma, or scrotal hernia (7).
- Sensitivity of radionuclide testicular scintigraphy is decreased relative to ultrasonography because hyperemia in the torsed testicle can mimic flow (8).

## **TREATMENT**

- Manual reduction: Best performed by experienced physician; may be successful, facilitated by lidocaine 1% (plain) injection at level of external ring
  - Difficult to determine success of manual reduction, especially after giving local anesthesia.
  - Manual reduction might require sedation, and the entire process may delay definitive treatment.
  - Even if successful, must always be followed by surgical exploration, urgently but not

- Surgical exploration via scrotal approach at the median raphe allows for exposure of both testes, detorsion, evaluation of testicular viability, orchidopexy of viable testicle, and orchiectomy of nonviable testicle (5)[B].
- In boys with a history of intermittent episodes of testicular pain, scrotal exploration is warranted with testicular fixation if abnormal testicular attachments are confirmed (5)[B].

## GENERAL MEASURES

Early exam is crucial because necrosis of the testicle can occur after 6 to 8 hours (1,9)[C].

## SURGERY/OTHER PROCEDURES

- Operative testicular fixation of the torsed testicle after detorsion and confirmation of viability. At least 3- or 4-point fixation with nonabsorbable sutures between the tunica albuginea and the tunica vaginalis (5)[B]
- Excision of window of tunica albuginea with suture to dartos fascia (5,10)[B]
- Any testis that is not clearly viable should be removed (5)[B].
- Testes of questionable viability that are preserved and pexed invariably atrophy (5)[B]
- Bilateral testicular fixation is recommended by many surgeons (5)[B].
- Contralateral testicle frequently has similar abnormal fixation and should be explored (5)[B],(6)[C].

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

### Patient Monitoring

- Postoperative visit at 1 to 2 weeks
- Yearly visits until puberty may be needed to evaluate for atrophy.

## DIET

Regular

## PATIENT EDUCATION

Possibility of testicular atrophy in salvaged testis with depressed sperm counts. Importantly, fertility rates in patients with one testicle remain excellent.

## PROGNOSIS

- Testicular salvage
  - Salvage is related directly to duration of torsion (85-97% if within 6 hours, 20% after 12 hours <10% if >24 hours) (9).
  - The degree of torsion is related to testicular salvage.
    - The median degree of torsion is <360 in patients who are explored and orchidopexy performed.
    - The median degree of torsion is 540 in patients who undergo exploration and require orchiectomy (3).
- 80-94% may have depressed spermatogenesis related to duration of ischemic injury (possibly related to autoimmune-mediated injury) (9).
- Up to 45% of patients undergoing orchiopexy for testicular torsion will develop atrophy of testicle.

## COMPLICATIONS

- Possible testicular atrophy
- Decreased or abnormal spermatogenesis
- Infertility
  - Fertility rates with one testicle remain excellent.
  - Nearly, 36% of patients who experience torsion have sperm counts <20 million/mL (8).

---

## Codes

**&NA;**

### ICD10

- N44.00 Torsion of testis, unspecified
- N44.03 Torsion of appendix testis
- N44.01 Extravaginal torsion of spermatic cord

## Clinical Pearls

**&NA;**

- The diagnosis of testicular torsion is usually made on physical exam. Patients with suspected

torsion should be taken to the OR without delay. If diagnosis is in question, a testicular Doppler US may be done to evaluate blood flow.

- Although testicular necrosis may be present within 6 to 8 hours of torsion, this is highly variable.
- Infertility can be a problem even if the testicle is viable. Autoimmune antibodies may be produced, and they may affect subsequent fertility.

# Testosterone Deficiency

Michael Lao, MD

Gregory Murphy, MD

Stanton C. Honig, MD

## BASICS

### DESCRIPTION

- Testosterone (T) is a critical anabolic hormone involved in various key metabolic pathways.
- It is the principle circulating androgen in males.
- Critical in modulating bodily processes of the cardiovascular, reproductive, hematologic, central nervous, and musculoskeletal systems
- Testosterone deficiency (TD), or hypogonadism, is characterized by low levels of T, often in addition with signs and symptoms attributed to low T levels.
- No universally accepted threshold of T concentration to distinguish eugonadal from hypogonadal men, but the FDA definition is T <300 ng/dL.
- Clinically, TD is divided into primary and secondary.
- T levels can be affected by medical conditions that influence the hypothalamic-pituitary-testis axis, age, and medical comorbidities.
- T levels correlates with overall health and may be associated with sexual function
- T levels decline by 1% per year after age 40.
- Special consideration is needed for men with low T who desire future fertility.
- Synonym(s): hypogonadism; hypoandrogenism; androgen deficiency; and low T

### EPIDEMIOLOGY

#### Incidence

- Overall incidence increases with age
- Symptomatic TD in men in United States ages 30 to 79 years is 5.6%
- 481,000 new cases in the United States in men 40 to 69 years

## Prevalence

- Estimates of TD vary widely, but typically 20% of men over 60, 30% over 70, and 50% over 80 years of age.
- 2 to 4 million men in United States

## ETIOLOGY AND PATHOPHYSIOLOGY

- Normal hypothalamic-pituitary-testis axis:
  - Hypothalamus produces GnRH, which stimulates pituitary to produce follicle-stimulating hormone (FSH) and luteinizing hormone (LH).
  - LH stimulates the leydig cells to produce T; responsible for 90% of the body's T.
  - T inhibits LH and GnRH through negative feedback at level of hypothalamus and pituitary.
- Primary hypogonadism: Testes produces insufficient amount of T, FSH/LH levels are elevated.
- Secondary hypogonadism: low T from inadequate production of LH
- Mixed hypogonadism: low to normal LH in combination with reduced production of T
- Normal aging process
- Congenital syndromes: cryptorchidism, Klinefelter
- Acquired: cancer, trauma, orchiectomy, prior anabolic steroid abuse
- Infectious: mumps orchitis, HIV, tuberculosis
- Systemic: Cushing syndrome, hemochromatosis, autoimmune, severe illness (e.g., renal disease, cirrhosis), metabolic syndrome, obesity, obstructive sleep apnea, hypogonadotropic hypogonadism
- Drugs and medications: LHRH agonists (leuprolide), corticosteroids, ethanol, ketoconazole, spironolactone, marijuana, opioids, cimetidine
- Elevated prolactin: prolactinoma, dopamine antagonists (e.g., neuroleptics and metoclopramide)

## Genetics

- Usually normal
- Klinefelter: XXY karyotype
- Kallmann: abnormal GnRH secretion due to abnormal hypothalamus development

## **RISK FACTORS**

- Obesity, diabetes, COPD, depression, hypothyroid, malnutrition, alcohol, stress
- Chronic infections or inflammatory diseases
- Medications that affect T production or metabolism
- Undescended testicles
- Trauma, testicular radiation, chemotherapy, disorders of the pituitary and/or hypothalamus

## **GENERAL PREVENTION**

General health maintenance and treatment of obesity

## **COMMONLY ASSOCIATED CONDITIONS**

- Infertility, erectile dysfunction, low libido
- Poorer health outcomes
- Osteopenia/osteoporosis and fractures
- Diabetes and insulin resistance, metabolic syndrome
- Increased body weight, adiposity
- Sleep disturbance and depressed mood, poor concentration, irritability

## **DIAGNOSIS**

### **HISTORY**

Check for

- Congenital and developmental abnormalities
- Infertility, loss of libido, erectile dysfunction (1)[A]
- Depression, fatigue, difficulty with concentration
- Decreased muscle strength, energy level
- Increase in body fat, development of diabetes
- Bone fractures from relatively minor trauma
- Testicular trauma, infection, radio- or chemotherapy
- Decrease in testicle size or consistency
- Headaches or vision changes suggesting pituitary dysfunction
- Medications

## *PHYSICAL EXAM*

- Infancy: ambiguous genitalia
- Puberty
  - Impaired growth of penis, testicles
  - Lack of secondary male characteristics
  - Gynecomastia, eunuchoid habitus
- Adulthood
  - Decreased muscular development, visceral fat distribution; body habitus changes to suggest corticosteroid excess
  - Presence of gynecomastia
  - Skin changes to suggest hemochromatosis
  - Eunuchoid habitus
- Genitourinary exam
  - Small and/or soft testicles

## *DIFFERENTIAL DIAGNOSIS*

- Delayed puberty
- Obesity
- Normal aging
- Prior anabolic steroid abuse

## *DIAGNOSTIC TESTS & INTERPRETATION*

- T levels vary widely, they are subject to diurnal, seasonal, and age-related variations. There are multiple assays, each with unique characteristics. Measurement should be obtained between 6 to 10 AM. Confirmation with a second measurement may be necessary. Whether total T or free T most closely correlates with symptomatic deficiency is unclear. Free T with total T is generally preferred. Measurements should not be obtained during acute or subacute illness. T circulates in blood primarily bound to SHBG or to albumin. Only 2-3% of total T is found free. Free and albumin-bound T is considered bioavailable. Laboratory findings must be interpreted in the appropriate clinical setting. Bioavailable T is considered most important, but assays are not readily available and calculated bioavailable T is not reliable.

- Lower limit of normal in most reference laboratories for total testosterone is 280 to 300 ng/dL (9.8 to 10.4 nmol/L). The lower limit of normal for free testosterone is 5 to 9 pg/mL (0.17 to 0.31 nmol/L).

### *Initial Tests (lab, imaging)*

- In symptomatic individuals, morning T level is the initial test. Morning timing is more important for younger men in whom there is more diurnal variation. If initial morning testosterone is low and confirmed on repeat test, further evaluation is appropriate (2)[A].
- Endocrine evaluation should include LH and FSH to differentiate between primary versus secondary hypogonadism.
- If primary hypogonadism of unknown origin, consider obtaining karyotype (e.g., Klinefelter) if severe testis atrophy exists.
- If secondary hypogonadism, evaluation may consist of prolactin, iron saturation, pituitary function testing, and/or MRI of pituitary.
- Imaging is not helpful in the initial diagnosis of TD.
- No evidence to support screening for TD in the general population

### *Follow-Up Tests & Special Considerations*

- Routine blood work to measure T response to interventions
- Dual-emission x-ray absorptiometry (DEXA) to measure bone mineral density in men with severe TD or fracture from minimal trauma.
- Pituitary MRI: if there is elevation of prolactin more than twice the upper limit of normal or LH/FSH below normal range

## **TREATMENT**

T replacement is recommended for symptomatic men (e.g., low libido and/or erectile dysfunction, low energy level, constitutional symptoms, etc.) with low T levels  $\geq 300$  ng/dL obtained in the morning. Not recommended for older men with low T levels in absence of signs or symptoms.

## **GENERAL MEASURES**

- Confirm suspicion.
- Obtain hematocrit, prostate-specific antigen (PSA) in men > 40 years, prolactin, LH/FSH, SHBG, estradiol.

Baseline physical exam including digital rectal exam, and International Prostate Symptom Score (IPSS)

- Correction of underlying cause
- Is future fertility an issue? Different treatment strategies are used in men of reproductive age and/or interest.

P.1025

- Current evidence fails to demonstrate that higher serum T is associated with greater prostate cancer risk.
- Safety of T therapy in prostate cancer is still uncertain and contraindicated in package insert.
- 2010 Endocrine Guidelines: Patients with organconfined prostate cancer who have undergone radical prostatectomy and have been disease free for <sup>3</sup>2 years after surgery with undetectable PSA may be considered for T replacement on an individualized basis. Lack of data from randomized trials precludes a general recommendation.
- T therapy should not be used in men with hematocrit >50%, untreated obstructive sleep apnea, and severe lower urinary tract symptoms with an IPSS >19 (3)[A].
- T therapy is not recommended for: mood or strength improvement in otherwise healthy men, or asymptomatic men with low T measurements (3)[A].
- Carefully weigh risks and benefits in men at elevated cardiovascular risk (3,4)[A].
- Clinicians can consider starting short-term T therapy as an adjunctive in men with HIV and low T to promote weight maintenance and gains in lean body mass and strength.

## MEDICATION

### ALERT

- Avoid contact with females or children (see package insert) in patients applying gel preparations.
- Oral therapy is not recommended due to significant hepatotoxicity.
- The FDA has cautioned that testosterone is approved for men with confirmed low testosterone by laboratory testing and caused by certain medical conditions, NOT just due to aging.
- Despite prior data showing no clear association between testosterone replacement therapy (TRT) and CV disease, there have been several recent papers suggesting that TRT use puts patients at an increased risk for CV disease. These papers have been criticized widely for being flawed due to comparison of unequal groups, short and inaccurate endpoints, flawed laboratory testing, erroneous exclusion criteria, and atypical statistical analysis. Despite this, an FDA panel concluded that there is a possible increased CV risk associated with testosterone

use.

- Testosterone replacement therapy (FDA approved)
  - Topical gels/solutions
    - Multiple FDA-approved formulations
    - Most frequently prescribed in United States
    - Mimics normal daily circadian rhythm
    - Good absorption, but 15-20% are nonresponders
    - Transfer concern to children and women
    - Dosage adjustments to obtain optimal results
    - Gel application: arms, back, axilla, and groin
  - Testosterone pellets (Testopel)
    - Minor office procedure with mild discomfort
    - Long-acting formulation, 3 to 4 months
    - 1-2% risk of infection or pellet extrusion
  - Transdermal patch (Androderm)
    - Achieves less robust levels
    - Convenient over gels, no risk of transference
    - High incidence of skin irritation
  - Testosterone cypionate and enanthate (short acting)
    - Injectable (IM), inexpensive
    - Inconvenient: injections every 1 to 3 weeks
    - Starting dose: 100 mg/week, or 200 mg/2 weeks
    - Roller coast effect: levels rise and fall
  - Testosterone undecanoate (long acting)
    - Injectable, expensive, convenient
    - Small risk of oil embolism, needs observation in office for 30 minutes postinjection
    - Given approximately every 8 to 12 weeks

## Buccal application (Striant)

- Adheres to gum line, irritation in 16.3%
- Poor compliance, every 12 hours application

## ■ Nasal gel (Natesto)

- Levels overdosing schedule are variable.
- TID dosing, nasal irritation

## ● OFF LABEL TREATMENT

### ■ Human chorionic gonadotropin (hCG)

- Structure similar to LH, mimicks its actions
- Frequent, 3 times per week starting at 1,500 IU SC
- Poor compliance
- Maintenance of testicular volume and fertility
- Used in men wanting to preserve fertility

### ■ Clomiphene citrate: oral agent

- Increases T by interfering with negative feedback, resulting in increased LH and FSH
- Starting dose of 25 mg daily 3 to 7 times weekly
- Used in men wanting to preserve fertility

### ■ Aromatase inhibitors (Arimidex): oral agent

- Blocks conversion of T to estradiol
- Does not negatively impact spermatogenesis and testicular volume
- Utilized in cases of low T/estradiol ratio

## *ISSUES FOR REFERRAL*

- Elevated PSA and/or abnormal prostate exam should be referred to urology.
- Worsening symptoms of BPH or increasing IPSS

## **ONGOING CARE**

# *FOLLOW-UP RECOMMENDATIONS*

## **Patient Monitoring**

- Necessary to monitor effectiveness of therapy as well as for adverse effects: Initially 3 to 6 months after treatment initiation and then annually
- Measure hematocrit at baseline, at 3 to 6 months, and then annually. If hematocrit >54% or symptomatic, stop therapy until hematocrit decreases to a safe level. Treatment includes phlebotomy, blood donation, or adjustment of dose.
- Evaluate patient for hypoxia or sleep apnea.
- Monitor bone mineral density after 1 to 2 years of therapy in these men with osteoporosis or low trauma fracture.
- Changes in voiding symptoms
- Prostate exam done regularly every 6 to 12 months.
- Refer to urology when increase in PSA >0.7 ng/mL within any 12-month period of T treatment or detection of prostatic abnormality on prostate exam.

## *DIET*

Healthy diet and weight reduction if obese

## *PATIENT EDUCATION*

- TD is chronic and likely to need lifelong therapy.
- T replacement comes with many risks, and it is very important to regularly monitor outcomes.
- Women and children must not be allowed to come in contact with T-replacement gel products.

## *PROGNOSIS*

- Sustained reversal of symptoms can be achieved when serum levels of T fall in the normal range.
- Adverse health effects seen in many with chronically low levels of T

## **COMPLICATIONS**

Complications of testosterone replacement

- Decreased testicular volume and azoospermia
- Fluctuations in mood or libido
- Gynecomastia and growth of breast cancer

- Acne and oily skin
- Erythrocytosis (increased hemocrit)
- Exacerbation of sleep apnea
- Hepatotoxicity with prolonged oral use
- Possible prostate enlargement with or without worsening symptoms of BPH
- Unknown cardiovascular risks

## Codes

&NA;

ICD10

- E29.1 Testicular hypofunction
- E89.5 Postprocedural testicular hypofunction

## Clinical Pearls

### **&NA;**

- Testosterone deficiency is common and prevalence increases with age.
- Testosterone deficiency can have negative adverse impact on many bodily systems.
- Symptomatic men with sexual dysfunction, obesity, and metabolic diseases should be tested for testosterone deficiency and treated.
- Initial test of choice is a morning total and free testosterone; if low, repeat measurements.
- Testosterone replacement therapy in the appropriately selected population can increase lean mass, reduce fat mass, increase bone density, improve libido, and improved erections.

# Thalassemia

Herbert L. Muncie Jr., MD

Garland Edward Anderson II, MD

## BASICS

### DESCRIPTION

- A group of inherited hematologic disorders that affect the synthesis of adult hemoglobin tetramer (HbA) (1,2)[C]
- $\alpha$ -Thalassemia is due to a deficient synthesis of  $\alpha$ -globin chain, whereas  $\beta$ -thalassemia is due to a deficient synthesis of  $\beta$ -globin chain:
  - The synthesis of the unaffected globin chain proceeds normally.
  - This unbalanced globin chain production causes unstable hemoglobin tetramers, which leads to hypochromic, microcytic RBCs, and hemolytic anemia.
- $\alpha$ -Thalassemia is more common in persons of Mediterranean, African, and Southeast Asian descent, whereas  $\beta$ -thalassemia is more common in patients of African and Southeast Asian descent.
- Types
  - Thalassemia (minor) trait ( $\alpha$  or  $\beta$ ): absent or mild anemia with microcytosis and hypochromia
  - $\alpha$ -Thalassemia major with hemoglobin Barts usually results in fatal hydrops fetalis (fluid in <sup>3</sup>2 fetal compartments secondary to anemia and fetal heart failure).
  - $\alpha$ -Thalassemia intermedia with hemoglobin H (hemoglobin H disease): results in moderate hemolytic anemia and splenomegaly
  - $\beta$ -Thalassemia major: results in severe anemia, growth retardation, hepatosplenomegaly, bone marrow expansion, and bone deformities. Transfusion therapy is necessary to sustain life.
  - $\beta$ -Thalassemia intermedia: Milder disease; transfusion therapy may not be needed or may be needed later in life.
- Other variants include hemoglobin E/ $\beta$ -thalassemia in Southeast Asians, which often

mimics the severity of  $\alpha$ -thalassemia major; delta thalassemia; hemoglobin H Constant Spring.

- System(s) affected: hematologic/lymphatic/immunologic, cardiac, hepatic
- Synonym(s): Mediterranean anemia; hereditary leptocytosis; Cooley anemia

### *Pediatric Considerations*

- $\beta$ -Thalassemia major causes symptoms during early childhood, usually starting at 6 months of age, and requires periodic transfusions to sustain life.
- Newborn's cord blood or heel stick should be screened for hemoglobinopathies with hemoglobin electrophoresis or comparably accurate test, although this primarily detects sickle cell disease.

### *Pregnancy Considerations*

- Preconception genetic counseling is advised for couples at risk for having a child with thalassemia and for parents or other relatives of a child with thalassemia (3)[A].
- Once pregnant, a chorionic villus sample at 10 to 11 weeks' gestation or an amniocentesis at 15 weeks' gestation can be done to detect point mutations or deletions with polymerase chain reaction (PCR) technology.

## **EPIDEMIOLOGY**

### **Incidence**

- Occurs in  $\div$  4.4/10,000 live births
- Predominant age: Symptoms start to appear 6 months after birth with  $\beta$ -thalassemia major.
- Predominant sex: male = female

### *Prevalence*

- Worldwide,  $\div$  200,000 people are alive with  $\beta$ -thalassemia major and  $<$  1,000 patients are in the United States.
- In the worldwide population, an estimated 1.5% are  $\beta$ -thalassemia carriers and 5%  $\alpha$ -thalassemia carriers (4).

## **ETIOLOGY AND PATHOPHYSIOLOGY**

Unknown; it is unclear how the imbalance of  $\beta$ -globulin in  $\alpha$ -thalassemia and  $\alpha$ -

globin in  $\alpha$ -thalassemia results in ineffective red blood cell genesis and hemolysis.

## Genetics

- Inherited in an autosomal recessive pattern.
- $\alpha$ -Thalassemia results from a deletion of 1 of the 4 genes, 2 on each chromosome 16, responsible for  $\alpha$ -globin synthesis. 1-gene deletion is a silent carrier state, 2-gene deletion is the trait, 3-gene deletion results in hemoglobin H, and 4-gene deletion results in hemoglobin Bart, causing fatal hydrops fetalis.
- Nondeletional forms do occur rarely. Hemoglobin H Constant Spring is the most common nondeletional form.
- $\beta$ -Thalassemia is caused by any of >200-point mutations and, very rarely, deletions on chromosome 11; 20 alleles account for >80% of the mutations.
- Significantly disparate phenotype with the same genotype occurs because  $\beta$ -globin chain production can range from near-normal to absent.

## RISK FACTORS

Family history of thalassemia

## GENERAL PREVENTION

- Prenatal information: genetic counseling regarding partner selection and information on the availability of diagnostic tests during the pregnancy
- Complication prevention
  - For offspring of adult thalassemia patients, an evaluation for thalassemia by 1 year of age
  - Severe forms
    - Avoid exposure to sick contacts.
    - Keep immunizations up to date.
  - Promptly treat bacterial infections. (After splenectomy, patients should maintain a supply of an appropriate antibiotic to take at the onset of symptoms of a bacterial infection.)
  - Dental checkups every 6 months
  - Avoid activities that could increase the risk of bone fractures.

## COMMONLY ASSOCIATED CONDITIONS

See ÒComplications.Ó

## DIAGNOSIS

Thalassemia (minor) trait has no signs or symptoms.

### HISTORY

- Poor growth
- Excessive fatigue
- Cholelithiasis
- Pathologic fractures
- Shortness of breath

### PHYSICAL EXAM

- Pallor
- Splenomegaly
- Jaundice
- Maxillary hyperplasia/frontal bossing due to massive bone marrow expansion
- Dental malocclusion

### DIFFERENTIAL DIAGNOSIS

- Iron deficiency anemia
- Other microcytic anemias: lead toxicity, sideroblastic
- Other hemolytic anemias
- Other hemoglobinopathies

### DIAGNOSTIC TESTS & INTERPRETATION

Special tests

- Bone marrow aspiration to evaluate for causes of microcytic anemia is rarely needed.
- Multiple indices have been evaluated to discriminate  $\alpha$ -thalassemia trait from iron deficiency anemia, yet none is sensitive enough to exclude  $\alpha$ -thalassemia.
- Hemoglobin: usual range 10 to 12 g/dL with thalassemia trait and 3 to 8 g/dL with  $\alpha$ -thalassemia major before transfusions.
- Hematocrit

- 28-40% in thalassemia trait
  - May fall to <10% in  $\beta$ -thalassemia major
- Peripheral blood
  - Microcytosis (MCV <70 fl)
  - Hypochromia (MCH <20 pg)
  - High percentage of target cells
  - Reticulocyte count is elevated.
- Red cell distribution width (RDW)
  - A normal RDW with a microcytic hypochromic anemia is almost always thalassemia trait.
  - The RDW can be elevated in  $\div$  50% of thalassemia trait patients. This is in contrast to iron deficiency anemia, where the RDW is almost always elevated (90%).
- Hemoglobin electrophoresis
  - In  $\alpha$ -thalassemia trait, no recognizable electrophoretic pattern occurs in adults.
  - However, in the neonatal period, 3-10% of trait patients will have hemoglobin H or hemoglobin Bart at birth, which would confirm  $\beta$ -thalassemia.
  - If HbA<sub>2</sub> is below normal (<2.5%) with a normal HbF level, the diagnosis is  $\alpha$ -thalassemia intermedia (HbH disease).
  - In the neonatal period with  $\beta$ -thalassemia trait, the electrophoresis is normal. However, in adults, elevated HbA<sub>2</sub> levels (>4%) may be present but are usually normal (5)[C].
  - $\beta$ -Thalassemia major or intermedia has elevated HbA<sub>2</sub>, elevated HbF, and reduced or absent HbA.
- DNA analysis
  - $\alpha$ -Thalassemia can definitively be diagnosed with genetic testing of hemoglobin A1 and A2 (for deletions and point mutations), but this is not routinely done due to the high cost.
  - High-performance liquid chromatography
  - Cost-effective primary screening tool for children and adolescents (6)[C]
  - Equivocal results should be confirmed with DNA analysis.

## *Pediatric Considerations*

For children, calculate Mentzer index (mean corpuscular volume/RBC count).

- <13: suggests thalassemia
- >13: suggests iron deficiency anemia
- Liver iron concentrations can be assessed with MRI (FerriScan).

## TREATMENT

- Outpatient for mild cases
- Inpatient for transfusion therapy

P.1027

## GENERAL MEASURES

- Mild cases (trait or minor) require no therapy.
- Thalassemia intermedia: No therapy is necessary unless hemoglobin falls to a level that causes symptoms; then transfusion therapy is needed. Decision is based on patient's quality of life.
- Iron supplements should not be given unless iron deficiency occurs and is confirmed with low ferritin. Supplements increase the risk of iron overload.
- Thalassemia major
  - A regular transfusion schedule to increase posttransfusion hemoglobin to 13.0 to 14.0 g/L and maintain a mean hemoglobin level of at least 9.3 g/dL (1.4 mmol/L)
  - Patients require >8 transfusion events per year. An event may be multiple transfused units.
  - Iron overload (7)[C]
    - Patients receiving transfusion therapy increase total body iron 4 times the normal amount.
    - Therapy is iron chelation. (See Medication.)

## MEDICATION

Thalassemia intermedia and major: folic acid supplements (1 mg/day)

### First Line

*&bgr;*-Thalassemia major

- Iron chelation with deferoxamine (Desferal)

- Usually continuous SC or IV infusion
  - Acute toxicity: initial 1,000 mg IV, may be followed by 500 mg every 4 hours for 2 doses; subsequent doses of 500 mg every 4 to 12 hours based on response (max 6,000 mg/day)
  - Chronic: 20 to 40 mg/kg over 8 to 12 hours daily
  - Usually started by 5 to 8 years of age
  - Treatment lasts 3 to 5 years to reach serum ferritin <1,000 ng/mL.
- Deferasirox (Exjade): 20 to 30 mg/kg/day PO acceptable alternative; approved for transfusion and non-transfusion-dependent patients with hepatic iron concentrations  $\geq 5$  mg/g of dry weight and serum ferritin  $>300$   $\mu$ g/L; renal and hepatic monitoring is recommended.

## Second Line

Chelation with deferiprone (Ferriprox) 25 mg/kg TID PO initially is an acceptable alternative for patients who have not responded to deferoxamine; may provide more cardioprotection. A drawback is weekly CBC because  $\approx 1\%$  of patients develop agranulocytosis.

## ISSUES FOR REFERRAL

Thalassemia major usually requires hematology consult.

## ADDITIONAL THERAPIES

*&bgr;*-Thalassemia intermedia

- Hydroxyurea may improve hemoglobin 1 to 2 g/dL.
- Psychological support seems appropriate for this chronic disease. However, no conclusions can be made regarding specific psychological therapies.

## SURGERY/OTHER PROCEDURES

- Splenectomy
  - May be needed if hypersplenism causes an increase in the transfusion requirements ( $>180$  to 200 mL/kg/year) (8)[C]
  - Defer surgery until patient is at least 4 years of age (due to increased infection risk).
  - Administer pneumococcal polyvalent-23 vaccine 1 month before splenectomy. Children should complete their pneumococcal conjugate vaccine series before surgery.
  - Daily penicillin prophylaxis, 250 mg BID, after splenectomy for 2 years for all patients and for children until age 16 years.

- Bone marrow transplantation with HLA-identical related donor stem cells in children before developing hepatitis or iron overload has high likelihood of remission but may impair fertility.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- Thalassemia trait requires no restrictions.
- *&bgr;*-Thalassemia major
  - Avoid strenuous activities (e.g., football, soccer).
  - Acceptable activity levels will be determined on an individual basis depending on the severity of the disorder.

### *Patient Monitoring*

- Thalassemia-trait patients require no special follow-up.
- For *&bgr;*-thalassemia major, lifelong monitoring is necessary because the therapy and disease progression have numerous potential complications.

### *DIET*

- Thalassemia trait requires no restrictions.
- *&bgr;*-Thalassemia major
  - Limit intake of iron-rich foods (e.g., red meats such as liver and some cereals).

### *PATIENT EDUCATION*

Printed patient information available from Cooley Anemia Foundation, 330 7th Ave. Suite 900, New York, NY 10001; <http://www.thalassemia.org> or <http://www.cooleyanemia.org>

### *PROGNOSIS*

- Outlook varies depending on type.
- Thalassemia-trait patients live a normal lifespan.
- *&bgr;*-Thalassemia major patients live an average of 17 years and usually die by age 30 years.
- Iron overload causes most of the morbidity and mortality:
  - Cardiac events are the primary cause of death.

- Myocardial iron deposition is best assessed with MRI T2 (9)[C].
- Effective iron chelation improves longevity.

## COMPLICATIONS

- Chronic hemolysis
- Susceptibility to infections after splenectomy
- Infections from blood transfusion
- Jaundice
- Leg ulcers
- Cholelithiasis
- Osteoporosis and low-trauma fractures
- Impaired growth rate
- Delayed or absent puberty
- Hypogonadism
- Hepatic siderosis
- Splenomegaly
- Cardiac disease from iron overload
- Thromboembolic phenomenon
- Aplastic and megaloblastic crises
- Increased risk of hematologic and abdominal cancer (10)
- Increased risk of dementia (11)

**&NA;**

## ICD10

- D56.9 Thalassemia, unspecified
- D56.1 Beta thalassemia
- D56.0 Alpha thalassemia

## Clinical Pearls

**&NA;**

- Thalassemia (group of inherited hematologic disorders that affect the synthesis of adult hemoglobin tetramer) is a genetic condition; hemoglobin will not improve over time.
- *&agr;*-Thalassemia is due to a deficient synthesis of the *&agr;*-globin chain, whereas *&bgr;*-thalassemia is due to a deficient synthesis of the *&bgr;*-globin chain.
- Hemoglobin electrophoresis is needed for genetic counseling but not to make the diagnosis of thalassemia minor when evaluating a patient with mild hypochromic, microcytic anemia, and normal serum ferritin.
- Anemia from thalassemia minor is not due to inadequate iron availability or iron storage. Therefore, iron supplements will not improve the anemia and could be harmful due to GI distress and iron overload. If coexisting iron deficiency is proven, then iron therapy is appropriate.

# Thoracic Outlet Syndrome

Muhammad Imran Khan, MD

Najm Hasan Siddiqui, MD

## BASICS

### DESCRIPTION

- A constellation of symptoms that affects the head, neck, shoulders, and upper extremities caused by compression of the neurovascular structures (i.e., brachial plexus and subclavian vessels) at the thoracic outlet, specifically in the area superior to the 1st rib and posterior to the clavicle
- Three forms of thoracic outlet syndrome (TOS) have been described: neurogenic, vascular (containing venous and arterial symptoms), and nonspecific (includes traumatic and secondary to certain provocative movements).
- Synonym(s): scalenus anticus syndrome; cervical rib syndrome; costoclavicular syndrome

### Pregnancy Considerations

Generalized tissue fluid accumulations and postural changes may aggravate symptoms.

### EPIDEMIOLOGY

#### Incidence

- Predominant age
  - Neurogenic type (95%): 20 to 60 years
  - Venous type (4%): 20 to 35 years
  - Arterial type (1%; atherosclerosis): young adult or >50 years
- Predominant sex
  - Neurogenic type: female > male (3.5:1)
  - Venous type: male > female
  - Arterial type: male = female

- No objective confirmatory tests are available to measure true incidence.
- Estimated 3 to 8/1,000 cases for neurogenic type
- Incidence of other TOS types is unclear.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

The interscalene triangle area is reduced in TOS and may become smaller during certain shoulder and arm movements. Fibrotic bands, cervical ribs, and muscle variations may further narrow the triangle. Trauma or provocative movements affecting the lower brachial plexus have strong implications in TOS pathogenesis.

- Three known causes of TOS: anatomic, traumatic/repetitive movement activities, and neurovascular entrapment
  - Anatomic: Variations in the anatomy of the neck scalene muscles may be responsible for presentations of the neurologic type of TOS and may involve the superior border of the 1st rib. Cervical ribs also have been implicated as a cause of neurologic TOS, with subsequent neuronal fibrosing and degeneration associated with arterial hyalinization in the lower trunk of the brachial plexus. Fibrous bands to cervical ribs are often congenital.
  - Trauma or repetitive movement activities: Motor vehicle accidents with hyperextension injury and resulting fibrosis, including fibrous bands to the clavicle; musicians who maintain prolonged positions of shoulder abduction or extension may be at increased risk.
  - Neurovascular entrapment: occurring in the costoclavicular space between the 1st rib and the head of the clavicle

## *RISK FACTORS*

- Trauma, especially to the shoulder girdle
- Presence of a cervical rib
- Posttraumatic, exostosis of clavicle or 1st rib, postural abnormalities (e.g., drooping of shoulders, scoliosis), body building with increased muscular bulk in thoracic outlet area, rapid weight loss with vigorous physical exertion and/or exercise, pendulous breasts
- Occupational exposure: computer users; musicians; repetitive work involving shoulders, arms, hands
- Young, thin females with long necks and drooping shoulders

## *GENERAL PREVENTION*

Consider observation or further evaluation in patients with cervical ribs.

## COMMONLY ASSOCIATED CONDITIONS

- Paget-von Schrötter syndrome: thrombosis of subclavian vein
- Gilliatt-Sumner hand: neurogenic atrophy of abductor pollicis brevis

## DIAGNOSIS

### HISTORY

- Neurologic type, upper plexus (C4-C7)
  - Pain and paresthesias in head, neck, mandible, face, temporal area, upper back/chest, outer arm, and hand in a radial nerve distribution
  - Occipital and orbital headache
- Neurologic type, lower plexus (C8-T1)
  - Pain and paresthesias in axilla, inner arm, and hand in an ulnar nerve distribution, often nocturnal
  - Hypothenar and interosseous muscle atrophy
- Venous type: arm claudication, cyanosis, swelling, distended arm veins
- Arterial type: digital vasospasm, thrombosis/embolism, aneurysm, gangrene

### PHYSICAL EXAM

- Positive Adson maneuver (head rotation to the affected side with cervical extension and then deep inhalation); test is positive if paresthesias occur or if radial pulse is not palpable during maneuver.
- Tenderness to percussion or palpation of supraclavicular area
- Worsening of symptoms with elevation of arm, overhead extension of arms, or with arms extended forward (e.g., driving a car, typing, carrying objects); prompt disappearance of symptoms with arm returning to neutral position
- Morley test
  - Brachial plexus compression test in the supraclavicular area from the scalene triangle
  - Positive with reproduction of an aching sensation and typical localized paresthesia
- Hyperabduction test: diminishment of radial pulse with elevation of arm above the head
- Military maneuver (i.e., costoclavicular bracing): When patient elevates chin and pushes shoulders posteriorly in an extreme *À*at-attention<sup>Ó</sup> position, symptoms are provoked.

- 1-minute Roos test
  - A thoracic outlet shoulder girdle stress test
  - Shoulders and arms are braced in a 90-degree abducted and externally rotated position; patient is required to clench and relax fists repetitively for 1 minute.
  - A positive test reproduces the symptom.

## *DIFFERENTIAL DIAGNOSIS*

- Cervical disk or carpal tunnel syndrome
- Orthopedic shoulder problems (shoulder strain, rotator cuff injury, tendonitis)
- Cervical spondylitis
- Ulnar nerve compression at elbow and hand
- Multiple sclerosis
- Spinal cord tumor/disease
- Angina pectoris
- Migraine
- Complex regional pain syndromes
- C3-C5 and C8 radiculopathies

## *DIAGNOSTIC TESTS & INTERPRETATION*

### **Initial Tests (lab, imaging)**

CBC, ESR, and C-reactive protein (CRP) determination may rule out underlying inflammatory conditions.

- Radiograph (chest, C-spine, shoulders) (1)[C] may reveal elongated C7 transverse process or a cervical rib, Pancoast tumor, or healed clavicle fracture.
- Nerve conduction studies and electromyography (EMG)
- CT scan or MRI, although MRI is the method of choice when searching for nerve compression
- Improved high-resolution MRN and tractography are valuable tools for identifying the source of nerve compression in patients with neurogenic TOS and can augment current diagnostic modalities for this syndrome (2)[B].
- Contrast-enhanced 3D MRA using provocative arm positioning allows excellent imaging of the arteries and veins on both sides and thus provides a noninvasive imaging alternative to digital

subtraction angiography in patients with suspected vascular TOS (3)[B].

- Doppler and duplex US if vascular obstruction is suspected
- Arteriogram and venogram have limited roles; useful when symptoms suggestive of arterial insufficiency or ischemia, or in planning surgical intervention (4)[C].

### *Diagnostic Procedures/Other*

No indicated procedures; anesthetic anterior scalene block may relieve pressure by scalene muscles on the brachial plexus, making this type of block diagnostic and potentially therapeutic, but it poses the risk of procedural damage to the brachial plexus.

### *Test Interpretation*

Systematic results of biopsy have not been reported. There is no indication for biopsy unless to investigate another underlying condition.

## **TREATMENT**

### *GENERAL MEASURES*

- Conservative management usually involves approaches to reduce and redistribute pressure and traction through the use of physiotherapy or prosthesis.
- Interscalene injections of botulinum toxin have been shown to decrease symptoms of TOS (5) [C]. A single, CT-guided Botox injection into the anterior scalene muscle may offer an effective, minimally invasive treatment for NTOS (6)[A].
- Physical therapy will develop strength in pectoral girdle muscles and achieve normal posture (1)[C].

P.1029

- Severe cases may use taping, adhesive elastic bandages, moist heat, TENS, or US but should not substitute active exercise and correction of posture and muscle imbalance (7)[B].

### *MEDICATION*

- No firm evidence exists for any approach to the four types of TOS.
- Physical therapy is the first-line treatment (7)[B].
- Anti-inflammatory (ibuprofen)
  - Adult dose: 400 to 800 mg PO q8h; not to exceed 3,200 mg/day
  - Pediatric dose

- <12 years: 10 mg/kg/dose every 6 to 8 hours
- >12 years: as in adults
- Contraindications: documented hypersensitivity, active PUD, renal or hepatic impairment, recent use of anticoagulants, hemorrhagic conditions
- Neuropathic pain: Tricyclic antidepressants, carbamazepine, gabapentin, phenytoin, pregabalin; muscle relaxants such as baclofen, metaxalone, or tizanidine may be helpful.
- Severe pain: Consider opiates for brachial plexus nerve block, steroid injections.

## *ISSUES FOR REFERRAL*

- Neurologic, anesthesiologic, orthopedic, vascular surgery referral(s) may be indicated depending on the type of pathologic condition.
- Physical and rehabilitation physicians

## *SURGERY/OTHER PROCEDURES*

- Operative if vascular involvement is present and/or loss of function or lifestyle occurs secondary to severity of symptoms and if conservative therapy fails after 2 to 3 months (1)[C]
- Resection of 1st rib or cervical ribs via transaxillary (preferred with good to excellent outcome 80% of patients), supraclavicular (good to excellent outcome 80% of patients), posterior approaches (reserved for complicated TOS due to necessity of large muscle incision). Excellent results were seen in patients who underwent first rib resection in all three forms of TOS (8)[A].
- Transaxillary 1st rib resection (TFRR) may provide better pain relief than supraclavicular neuroplasty of the brachial plexus (SNBP); although, overall, both treatment options have generally positive outcomes (9)[B].
- Transaxillary approach provides a good exposure and cosmetics in patients with TOS. It should be considered as the gold standard in the management of TOS (10)[B].
- Supraclavicular scalenectomy (11)[C]
- Isolated pectoral minor tenotomy (PMT) is a low-risk outpatient procedure that is effective for the treatment of selected patients with disabling NTOS, with early outcomes similar to supraclavicular decompression + PMT (12)[A].
- Excision of adhesive bands, anterior scalenectomy (13)[B]

## *INPATIENT CONSIDERATIONS*

## Admission Criteria/Initial Stabilization

Conservative, outpatient, nonpharmacologic treatment is reasonable first-line therapy except in cases of thromboembolic phenomena and acute ischemia, symptoms of chronic vascular occlusion, stenosis, arterial dilatation, or progressive neurologic deficit (7)[B].

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Correct improper posture, practice proper posture, exercises to strengthen shoulder elevator and neck extensor muscles, stretching exercises for scalene muscles, support bra for women with pendulous breasts, breast reduction surgery in selected cases; sleep with arms below chest level, avoid/reduce prolonged hyperabduction.

### *Patient Monitoring*

Office follow-up visits every 3 to 4 weeks

### *PATIENT EDUCATION*

Physical therapy, postural exercises, ergonomic workstation

### *PROGNOSIS*

Follow-up from surgery at mean of 7.5 years showed that functional results were excellent, good, fair, and poor in 87 (49.4%), 61 (34.6%), 14 (8%), and 14 (8%) procedures, respectively (14).

Durable long-term functional outcomes can be achieved predicated on a highly selective approach to the surgical management of patients with TOS. A majority of operated patients will not require adjunctive procedures or chronic narcotic use (15).

### **COMPLICATIONS**

- Postoperative shoulder, arm, hand pain, and paresthesias in 10%
- Patients who will have symptomatic recurrences at 1 month to 7 years postoperatively (usually within 3 months): 1.5-2%
- Patients who will have brachial plexus injury, probably due to intraoperative traction: 0.5-1%
- Reoperation is indicated for symptomatic recurrence with long posterior remnant of 1st rib (posterior approach) or with disrupted fibrous adhesions (transaxillary approach).
- Venous obstruction or arterial emboli; usually responds to thrombolytics

Povlsen B, Belzberg A, Hansson T, et al. Treatment for thoracic outlet syndrome. *Cochrane Database Syst Rev.* 2010;(1):CD007218.

## Codes

&NA;

### ICD10

G54.0 Brachial plexus disorders

## Clinical Pearls

&NA;

- Consider breast reduction for patients with pendulous breasts.
- Avoid opiate dependence.
- Consider pain clinic referral if there are nonsurgical causes.

# Thrombophilia and Hypercoagulable States

Kirsten Vitrikas, MD

## BASICS

### DESCRIPTION

- An inherited or acquired disorder of the coagulation system predisposing an individual to thromboembolism (the formation of a venous, or less commonly, an arterial blood clot) (1)
- Venous thrombosis typically manifests as deep venous thrombosis (DVT) of the lower extremity in the legs or pelvis and pulmonary embolism (PE) (1).
- System(s) affected: cardiovascular, nervous, pulmonary, reproductive, hematologic
- Synonym(s): hypercoagulation syndrome; prothrombotic state

### EPIDEMIOLOGY

- An inherited thrombophilic defect or risk can be detected in up to 50% of patients with venous thromboembolism (VTE).
- Factor V Leiden is the most common inherited thrombophilia (1/2 of all currently characterizable inherited thrombophilia cases involve the factor V Leiden mutation), and it is present in its heterozygous form in up to ÷ 20% of patients with a first VTE.
- Heterozygous prothrombin G20210A mutation, the second most common inherited thrombophilia, is present in up to ÷ 8% of patients with VTE.

### Incidence

First-time thromboembolism

- ÷ 100/100,000/year among the general population
- <1/100,000/year in those age <15 years
- ÷ 1,000/100,000/year in those age ≥85 years

### Prevalence

- 40-80% of lower extremity orthopedic procedures can result in DVT if prophylaxis is not used.

VTE accounts for ÷ 1.2 to 4.7 deaths per 100,000 pregnancies.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Virchow triad as a cause of VTE includes blood stasis, vascular endothelial injury, and abnormalities in circulating blood constituents (i.e., hypercoagulability).
- An imbalance between the hemostatic and fibrinolytic pathways leads to thrombus formation.
- VTE is considered to be the result of genetic tendencies with other acquired risks.
- Upper extremity DVT: >60% are associated with venous catheters. Malignancy is an additional significant risk (2).

### *Genetics*

- The most common genetic thrombophilias (factor V Leiden, prothrombin G20210A, proteins C and S, and antithrombin III deficiency) are inherited in an autosomal dominant pattern.
- Homozygous mutations generally have a higher risk of VTE.
- Factor V Leiden/activated protein C (aPC) resistance is the most common inherited thrombophilia.
  - 2-5% prevalence among Caucasians; rare in African Americans or Asians
  - aPC does not cleave factor Va, so thrombin formation continues.
  - Other acquired risks are synergistic (3).
- Prothrombin gene mutation G20210A: prevalence 6% among Caucasians. Heterozygous carriers have increased risk of thrombosis.
- Hyperhomocysteinemia: 5-6% among the general population; increases risk of coronary artery disease/myocardial infarction, cerebrovascular accident, and DVT/PE; acquired in those with folate, vitamin B 12, and vitamin B 6 deficiencies
- Antithrombin deficiency: <0.2% among the general population; produced in the liver; acquired deficiency in disseminated intravascular coagulation (DIC), sepsis, liver disease, nephrotic syndrome
- Protein C and S deficiencies: 0.5% and 1% incidences, respectively, among the general population. Homozygotes and heterozygotes are hypercoagulable. Vitamin K-dependent, produced in the liver. Protein C inactivates Va and VIIIa. Protein C may become an acquired deficiency in liver disease, sepsis, DIC, acute respiratory distress syndrome, and after surgery. Protein S is a cofactor for protein C, and it may become an acquired deficiency with oral contraceptive pill (OCP) use, pregnancy, liver disease, sepsis, DIC, HIV, and nephrosis.

# RISK FACTORS

- Acquired risk factors
  - Immobilization or prolonged travel
  - Trauma
  - Surgery, especially orthopedic
  - Malignancies (especially pancreatic, ovarian, brain, and lymphoma)
  - Pregnancy
  - Acute medical illness
  - Exogenous female hormones/oral contraceptives
  - Obesity
  - Nephrotic syndrome
  - Antiphospholipid syndrome (APS) and lupus anticoagulant
  - Myeloproliferative disorders (polycythemia vera, essential thrombocythemia)
  - Hyperviscosity syndromes (sickle cell, paraproteinemias)
  - Hyperhomocysteinemia secondary to vitamin deficiencies (B<sub>6</sub>, B<sub>12</sub>, folic acid)
  - Tamoxifen, thalidomide, lenalidomide, bevacizumab, L-asparaginase, erythropoietic stimulating agents
  - Previous thromboembolism
- Established genetic factors
  - Factor V Leiden
  - Prothrombin G20210A mutation
  - Protein C deficiency
  - Protein S deficiency
  - Antithrombin III deficiency
- Rare genetic factors
  - Dysfibrinogenemia
  - Hyperhomocysteinemia (methylene tetrahydrofolate reductase mutation)
- Indeterminate factors

- Elevated factor VIII
- Age: >60 years
- Gender: men
- Race: Incidence is higher among African Americans.

## GENERAL PREVENTION

- Consider prophylaxis with medications in any hospitalized patient with VTE risk factors; hospitalized patients should be encouraged to ambulate as soon as possible (4)[A].
- Consider mechanical prophylaxis in patients at increased risk for VTE in whom anticoagulation may be contraindicated (4)[A].
- Consider prophylaxis with low-molecular-weight heparin (LMWH) plus aspirin in pregnant patients with APS or other thrombophilia.
- Consider prophylaxis using LMWH in patients with solid tumors who have additional risk factors for VTE.
- Prophylaxis with unfractionated heparin (UFH) or LMWH should be considered in patients with genetic or acquired risks of thrombosis and an anticipated additional risk, such as the immobilization associated with surgery.
- Use caution with procoagulant medicines (e.g., OCPs) in asymptomatic individuals who have a known hereditary predisposition.

## COMMONLY ASSOCIATED CONDITIONS

Advanced age, cancer, pregnancy, obesity, prior history of thrombosis, surgery, immobilization

## DIAGNOSIS

### HISTORY

Consider prothrombotic assessment for the following:

- Unprovoked thrombosis at age <45 to 50 years
- Thrombosis at an unusual anatomic site or recurrent thromboses
- Family history suggesting multiple individuals affected with VTE
- Recurrent pregnancy loss or thrombosis with OCP use

## PHYSICAL EXAM

DVT: swelling, pain, warmth, and redness, usually of one extremity

- PE: dyspnea, pleurisy, hemoptysis, hypoxia, tachycardia
- Superficial phlebitis: red, painful cord palpable along the path of thrombosed vein
- Postthrombotic syndrome: pain, swelling, pigmentation, and/or ulceration

## **DIAGNOSTIC TESTS & INTERPRETATION**

Testing for heritable thrombophilia in all patients with a first episode of VTE is not required (2,5) [B].

### **Initial Tests (lab, imaging)**

- CBC
- aPC profile:  $\geq 2.0$  implies factor V Leiden mutation; 95-100% are factor V Leiden-positive; false-positive finding in pregnancy or with use of OCPs, confirm with factor V Leiden mutation testing or consider Factor V Leiden mutation testing up front.
  - aPC resistance may be unreliable while taking LMWH or UFH.
- Prothrombin G20210A genetic assay
- ATIII functional assay
  - Will be low with acute thrombosis and on heparin therapy
- Protein C functional assay
  - May be low with acute thrombosis; will be lower on warfarin
- Protein S antigen and functional assay and free S
  - May be low with acute thrombosis; will be lower on warfarin
- Antiphospholipid antibodies: phospholipid-dependent tests and anticardiolipin antibodies, lupus anticoagulant
  - May be unreliable on heparin
- Consider evaluation for subclinical malignancy in an unprovoked thrombosis in those >40 years of age or at greater risk.
- Consider homocysteine level, although treatment of hyperhomocysteinemia (vitamins B<sub>12</sub> and B<sub>6</sub>, folate) does not alter the thrombophilic risk.

## Follow-Up Tests & Special Considerations

Dysfibrinogenemia and plasminogen deficiency are very rare causes of thrombophilia.

## TREATMENT

### MEDICATION

#### First Line

- Parenteral anticoagulation: LMWH has largely replaced UFH as first-line therapy for VTE.
  - Enoxaparin (Lovenox): 1 mg/kg SC BID for at least 5 days (with concomitant warfarin) until international normalized ratio (INR) has reached 2 for at least 24 hours; adjust dose for renal disease.
    - Enoxaparin is preferred in patients with active cancer for a minimum of 6 months (can dose at 1.5 mg/kg SC daily), after which time the patient can be reevaluated to continue enoxaparin or transition to warfarin (4).
    - Adverse reactions: bleeding, heparin-induced thrombocytopenia (HIT) <0.5% incidence, bone loss (uncommon)
    - Reversal: Stop LMWH.
  - UFH: 80 U/kg or 5,000 U IV bolus, then 18 U/kg/hr or 1,000 U/hr to target the activated partial thromboplastin time (aPTT) to a corresponding anti-Xa level of 0.3 to 0.7 U/mL. The first aPTT should be checked 6 hours after initial therapy and adjusted per standard heparin nomograms, aiming for an adequate level within 24 hours. Transition to warfarin is similar to the recommendations for enoxaparin.
    - SC UFH is an alternative and can be given as 5,000 U IV (once) followed by 250 U/kg SC BID, or 250 U/kg bolus followed by 250 U/kg BID (monitored as for IV UFH), or 333 U/kg once followed by 250 U/kg SC BID (unmonitored).
    - Adverse reactions: bleeding, HIT 3% incidence, bone loss (long-term use)
    - Reversal: Stop heparin, protamine.
- Oral anticoagulation
  - Warfarin (Coumadin): 10 mg/day initially and adjust to INR 2 to 3 for at least 3 months, potentially indefinitely in those with high risk of recurrence, recurrent or unprovoked VTE
    - Warfarin requires careful and frequent monitoring because of many drug-drug and drug-diet (e.g., vitamin K) interactions.

- Adverse reactions: bleeding, skin necrosis (rare and early in course)
- Reversal: four-factor prothrombin complex concentrate (PCC); fresh frozen plasma and/or vitamin K
- Pregnancy (controversial): Low-dose aspirin and/or LMWH or UFH; warfarin is contraindicated.
- Several other newly approved anticoagulant medications are indicated for acute management. Their main benefit is the decreased need for frequent testing. However, most of the new medications do not have a reversal agent.

## *Second Line*

Usually indicated when contraindication to heparin or LMWH, such as heparin-associated thrombosis and thrombocytopenia, if there is an inability to use IV drugs, or renal failure. Direct oral anticoagulants may become first line as more clinical experience is developed.

- Factor Xa inhibitors
  - Fondaparinux: acute VTE/PE. Weight <50 kg: 5 mg/day SC; weight 50 to 100 kg: 7.5 mg/day SC; weight > 100 kg: 10 mg/day SC; use for 5 to 9 days until oral anticoagulation is therapeutic.
    - Prophylaxis: 2.5 mg/day SC
    - Dose adjustments: needed for renal insufficiency; if creatinine clearance is <30 mL/min, use is contraindicated.
- Oral factor Xa inhibitors
  - Rivaroxaban: FDA-approved for postoperative thromboprophylaxis after hip/knee replacement, treatment of DVT/PE, and for thromboembolic prophylaxis in patients with nonvalvular atrial fibrillation (6)[C]
  - Apixaban: can be used without need for preceding heparin therapy, less renal clearance than other oral anticoagulants
  - Edoxaban: requires treatment with heparin prior to initiation, needs adjustment for renal impairment
- Direct thrombin inhibitors: most commonly used for anticoagulation in HIT. Representative drugs include the following:
  - Lepirudin: excreted by kidneys, crosses the placenta; dosing based on creatinine clearance; therapeutic dose based on aPTT
  - Argatroban: liver metabolized; may be doseadjusted in liver dysfunction; therapeutic dose

based on aPTT

- Dabigatran: oral direct thrombin inhibitor, FDA-approved for treatment of DVT/PE after parenteral anticoagulant and for thromboembolic prophylaxis in patients with nonvalvular atrial fibrillation (noninferior to warfarin). Reversal agent newly available. May be dialyzable (6)[C]

## ***SURGERY/OTHER PROCEDURES***

- Catheter extraction/thrombectomy or thrombolysis for unstable cases (e.g., massive PE with hypotension)
- Inferior vena cava filter
  - Reduces short-term risk of PE in those with contraindications to anticoagulation (e.g., GI bleeding, cerebral hemorrhage)
  - May increase long-term risk of recurrent DVT
  - Used for patients with multiple episodes of recurrent thromboembolism despite therapeutic anticoagulation and contraindication to anticoagulation

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Avoid significant risk for trauma (e.g., contact sports, climbing a ladder).

### ***Patient Monitoring***

Monitor warfarin as frequently as needed to maintain an INR goal of 2 to 3.

### ***DIET***

Vitamin K-stable diet if patient is taking warfarin

## ***PATIENT EDUCATION***

- Assume that any drug may enhance or attenuate the warfarin effect.
- Increase the frequency of monitoring following any medication change to ensure therapeutic anticoagulation and to avoid overanticoagulation, especially with antibiotics.
- Many drugs may modulate warfarin effect: alcohol, antibiotics, aspirin, NSAIDs, acetaminophen.

## PROGNOSIS

- Anticoagulation should be continued for 3 months and consideration of longer in those with unprovoked VTE.
- Patients with a provoked VTE (i.e., surgery, hospitalization) not receiving chronic anticoagulation have a risks of recurrence of 7% (year 1), 16% (year 5), and 23% (year 10).
- Patients with an unprovoked VTE not receiving chronic anticoagulation have risks of recurrence of 15% (year 1), 41% (year 5), and 53% (year 10).
- Currently, there are no data from randomized controlled trials or controlled clinical trials about the benefits of thrombophilia testing to decrease the risk of recurrent VTE (1).

## COMPLICATIONS

Venous or arterial thrombosis; bleeding in anticoagulated patients

## Codes

**&NA;**

### ICD10

- D68.59 Other primary thrombophilia
- D68.51 Activated protein C resistance
- D68.2 hereditary deficiency of other clotting factors

## Clinical Pearls

**&NA;**

- Factor V Leiden (resistance to aPC) is the most common inherited thrombophilia, with a prevalence of 2-7% in the U.S. Caucasian population.
- Test patients <50 years of age with a history of venous thrombosis, and consider testing first-degree relatives.
- Rule out malignancy, especially in those >50 years of age.

# Thrombotic Thrombocytopenic Purpura

Hedy Smith, MD, PhD

Kellie A. Sprague, MD

## BASICS

### DESCRIPTION

- An acute syndrome of microangiopathic hemolytic anemia (MAHA) and consumptive thrombocytopenia with deposition of hyaline thrombi in terminal arterioles and capillaries leading to ischemic multiorgan damage
- Thrombotic thrombocytopenic purpura (TTP) is characterized by MAHA and thrombocytopenia, with or without the following signs and symptoms (1):
  - Neurologic symptoms
  - Renal dysfunction
  - Fever
  - Most patients do not show the historic pentad of MAHA, thrombocytopenia, renal dysfunction, neurologic abnormalities, and fever because treatment is initiated before the pentad can develop.

### EPIDEMIOLOGY

#### Incidence

- Predominant age: 18 to 49 years
- Predominant sex: female > male (3:1)
- Incidence ratio in blacks to whites is 7:1
- The age-sex-race standardized incidence of clinically suspected TTP is 8 million/year and 2 million/year in those with ADAMTS13 levels <10% (2).

### ETIOLOGY AND PATHOPHYSIOLOGY

- In TTP, the aggregating agent responsible for platelet thrombi is unusually large von Willebrand factor (UL vWF) multimers, which are far larger than those found in normal plasma.

- A metalloproteinase, ADAMTS13, which normally enzymatically cleaves UL vWF multimers to prevent clumping within vessels, is deficient, defective, or absent, allowing UL vWF to react with platelets. This leads to the endothelial cell damage and disseminated thrombi characteristic of TTP.
- Arterioles most often affected are in the brain, kidney, pancreas, heart, and adrenal glands. Lungs and liver are relatively spared.
- In familial TTP, patients have an inherited deficiency of ADAMTS13 (1).
- In acquired idiopathic TTP, autoantibodies are directed against the metalloproteinase ADAMTS13 (1,3).
- Endothelial injury, either directly from a drug/toxin or indirectly via platelet/neutrophil activation has been proposed as a cause of secondary TTP especially in those without ADAMTS13 deficiency.
  - Drug-induced (see "Risk Factors")
  - Hematopoietic cell transplantation

## *Genetics*

TTP is most often an acquired disorder. A congenital form of inherited TTP (Schulman-Upshaw syndrome) is due to a mutation at the ADAMTS13 metalloproteinase gene locus on chromosome 9q34. This rare form of TTP has an autosomal-recessive pattern of inheritance (4).

## **RISK FACTORS**

- Pregnancy and oral contraceptives
- AIDS and early symptomatic HIV infection
- Autoimmune disease
  - Antiphospholipid antibody syndrome
  - Systemic lupus erythematosus
  - Scleroderma
- Cancer
- Hematopoietic stem cell transplantation
- Drug toxicity
  - Cancer chemotherapy
    - Mitomycin C and gemcitabine

- Bleomycin and cisplatin
- Bevacizumab
- Calcineurin inhibitors
  - Tacrolimus and cyclosporine
- Immune-mediated
  - Quinine and quinidine
  - Ticlopidine and clopidogrel

## COMMONLY ASSOCIATED CONDITIONS

- TTP/HUS/atypical HUS (hemolytic uremic syndrome) have similar presentations with MAHA and thrombocytopenia and multiorgan involvement.
- TTP generally presents with minimal renal involvement and may have neurologic abnormalities, whereas the opposite is more characteristic of HUS/atypical HUS.
- However, patients with HUS and TTP may have both prominent renal and neurologic manifestations, often making the diagnosis unclear, hence the historical hybrid name ÔTTP-HUS.Ó
- ADAMTS13 levels are diminished in adults with familial or acquired idiopathic TTP but are normal in children diagnosed with HUS following infection with *Escherichia coli* (particularly type O157:H7), so-called Shiga toxin-HUS, and in Ôatypical HUS,Ó is also called complement mediated thrombotic microangiopathy reflecting the pathophysiology which is related to complement dysregulation.

## DIAGNOSIS

- Most common symptoms are nonspecific: nausea, vomiting, weakness, abdominal pain, fatigue, fever
- Related to thrombocytopenia
  - Easy bruising, purpura, or petechiae
  - Epistaxis, menorrhagia, bleeding gums
  - GI bleeding
  - Intracranial hemorrhage

Visual symptoms due to retinal hemorrhage

- Related to hemolytic anemia (MAHA): jaundice, fatigue
- Related to end-organ ischemia
  - Neurologic: CNS symptoms occur in 50%.
    - Often fluctuating symptoms
    - Headache
    - Altered mental status: Spectrum runs from behavioral/personality changes to obtundation/stupor/coma.
    - Seizures
    - Stroke
  - Renal: hematuria, oliguria, or anuria
  - Cardiac: arrhythmia, myocardial infarction, heart failure

## HISTORY

- Generally acute onset of symptoms but subacute in about 1/4 of patients
- It is important to assess for potential underlying causes or risk factors (see discussion earlier).

## PHYSICAL EXAM

- Fever
- Mental status/neurologic: confusion, coma, stupor, weakness
- HEENT: retinal hemorrhage, scleral icterus, epistaxis
- Abdomen/GI: nonspecific tenderness
- Skin: jaundice, petechiae, purpura, ecchymoses

## DIFFERENTIAL DIAGNOSIS

- HUS and atypical HUS: See Commonly Associated Conditions.
- Antiphospholipid antibody syndrome: prolonged partial thromboplastin time (PTT) and presence of lupus anticoagulant
- Systemic lupus erythematosus
- Malignant hypertension (HTN): diastolic > 130 mm Hg, papilledema, retinal hemorrhages

- Pregnancy-associated preeclampsia/eclampsia or hemolysis, elevated liver enzyme levels, and low platelet HELLP levels: low ATIII levels
- Disseminated intravascular coagulation
  - Prolonged prothrombin time (PT)/PTT, low fibrinogen
  - Low factors V and VIII
  - Secondary to sepsis/shock or widely disseminated malignancy
- Idiopathic thrombocytopenic purpura (ITP)
  - No hemolysis, normal lactate dehydrogenase (LDH) and bilirubin
  - Presence of antiplatelet antibodies
- Malignancy-associated microangiopathy
- Evan syndrome (autoimmune hemolytic anemia and thrombocytopenia): positive direct Coombs test
- Sclerodermal kidney

## *DIAGNOSTIC TESTS & INTERPRETATION*

### **Initial Tests (lab, imaging)**

- CBC
  - Hemoglobin (decreased): average is 8 to 10 g/dL
  - Platelets decreased: typically in the 10 to 30,000 range
- Reticulocyte count (increased)
- Haptoglobin decreased (hemolysis)
- Peripheral smear
  - Schistocytes (prominent, >1% of RBCs)
  - Helmet cells, RBC fragments
  - Nucleated RBCs
  - Polychromasia (reticulocytosis)
- Coagulation studies
  - Normal in most; mild elevation in 15%

Fibrinogen normal

- Coombs test: negative direct Coombs test
- Electrolytes, BUN/creatinine: mild elevation of BUN and creatinine (creatinine <3 mg/dL)
- Liver function studies: increased indirect bilirubin (hemolysis)
- LDH: 5 to 10 times normal
- Urinalysis
  - Proteinuria, microscopic hematuria
  - Positive dipstick for large blood, but minimal RBCs on microscopic exam
- ECG: sinus tachycardia, heart block
- Troponin: increased if cardiac involvement
- HIV, hepatitis A, B, C testing: Exclude underlying viral precipitant.
- Pregnancy test
- Pretreatment ADAMTS13 activity level of <10% is useful in distinguishing acquired or familial TTP from other disorders.
- Head CT/MRI scan: performed if mental status changes are present to rule out possible intracranial hemorrhage or ischemic changes

---

P.1033

## Test Interpretation

Biopsy of affected organs shows platelet thrombi within or beneath damaged endothelium. However, biopsy is rarely obtained because the diagnosis is made on clinical grounds and laboratory findings.

## TREATMENT

- Prompt treatment of TTP is necessary due to the high mortality (90%).
- In the absence of another apparent cause, the dyad of MAHA and thrombocytopenia is sufficient to begin treatment for TTP while the workup proceeds (1,3):
  - Plasma exchange transfusion (PEX) is the cornerstone of treatment of classic TTP (3)[A].
  - PEX replaces deficient or defective metalloproteinase (ADAMTS13) and removes UL vWF and antimetalloproteinase antibodies.
  - PEX should begun immediately and continued daily.

- Optimal PEX duration is variable. Convention is to continue for 2 days after platelet count is  $\geq 150,000$ , then consider tapering (5)[C].
- Fresh frozen plasma: temporary measure until PEX can be initiated (3)[B]

## *MEDICATION*

### **First Line**

- Glucocorticoids may be of benefit in some patients. British guidelines recommend its use for all patients (5)[B].
  - Steroids may work by suppressing the autoantibodies inhibiting ADAMTS13 activity.
  - Use may be in patients with severe ADAMTS13 deficiency, in the setting of exacerbation when PEX is stopped or in relapse after remission.
  - Little benefit of steroids when used as monotherapy
  - Doses: prednisone 1 mg/kg/day and taper once in remission or methylprednisolone 1 g/day IV for 3 days
- Rituximab, an anti-CD20 antibody that deletes B cells, may reduce relapse when given in conjunction with PEX and steroids (6).
  - Dose: 375 mg/m<sup>2</sup> IV weekly for 4 weeks

### *Second Line*

The following medications are used in refractory cases:

- Rituximab (5)[B]
- Vincristine, cyclophosphamide cyclosporine
- Intravenous immunoglobulin (IVIG) (3)
- Bortezomib (7)[C],(8)

## *ISSUES FOR REFERRAL*

- Hematology or blood bank for PEX
- Nephrology for dialysis
- Cardiology for presence of significant heart block or ischemia
- Neurosurgery for intracranial hemorrhage

## *SURGERY/OTHER PROCEDURES*

Splenectomy is reserved for severe, refractory cases (9).

## *INPATIENT CONSIDERATIONS*

### **Admission Criteria/Initial Stabilization**

- ABCs, oxygen, IV access, telemetry
- Volume resuscitation if hypotensive/actively bleeding
- Packed RBCs can be transfused safely.
- Platelet transfusion may be used for the treatment of hemorrhage.

### *Discharge Criteria*

On normalization and stabilization of neurologic symptoms, LDH, platelets, and renal function

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- No maintenance therapy is required. After PEX is discontinued, blood counts should be monitored over a few months. If testing results remain normal, testing interval can be lengthened.
- Promptly evaluate any symptoms of relapse.

### *PATIENT EDUCATION*

- On discharge, advise patients to self-monitor for signs of relapse (e.g., fever, headache, bruising).
- Patients should be advised about prolonged periods of fatigue following the acute phase.
- See National Heart, Lung, and Blood Institute Web site:  
<http://www.nhlbi.nih.gov/health/health-topics/topics/ttp>

### *PROGNOSIS*

- Most patients recover fully from idiopathic TTP when treated promptly:
  - 30-day mortality is 10% in those who receive PEX.
  - 70% respond within 14 days; 90% respond within 28 days.

- 80% survival in patients with idiopathic TTP treated with PEX (10)
- Initial LDH and platelet counts are not predictive of the patient's response to treatment.
- Final platelet count and LDH or the length or intensity of treatment does not predict relapse.
- Low levels of ADAMTS13 activity during remission are associated with higher risk of relapse (11).
- In patients with severe ADAMTS13 deficiency, the risk of relapse is estimated to be 41% at 7.5 years, with the greatest risk being in the first year.

## COMPLICATIONS

- Patients may experience mild cognitive impairments in attention, concentration, and memory following 1 episodes of TTP.
- Complications of PEX include the following:
  - Central line infections and hemorrhage
  - Citrate toxicity
  - Hypersensitivity reactions to frequent plasma exposure
  - Electrolyte abnormalities

## Codes

&NA;

### ICD10

- M31.1 Thrombotic microangiopathy
- D69.42 Congenital and hereditary thrombocytopenia purpura

- D69.3 Immune thrombocytopenic purpura

## Clinical Pearls

### &NA;

- The diagnosis of TTP is made clinically; common symptoms are nonspecific: nausea, vomiting, weakness, abdominal pain, fatigue, fever, and easy bruising, purpura, or petechiae.
- The historical pentad of fever, neurologic symptoms, renal dysfunction, MAHA, and thrombocytopenia is not present in most patients.
- The dyad of MAHA and thrombocytopenia is sufficient to initiate treatment with PEX.
- Do not wait for results of ADAMTS13 determination to initiate therapy.

# Thyroid Malignant Neoplasia

James P. Miller, MD

## BASICS

### DESCRIPTION

Thyroid malignant neoplasia is an autologous growth of thyroid nodules with potential for metastases.

- Papillary carcinoma
  - Most common variety, 60-70% of thyroid tumors
  - Peak incidence in the 3rd to 4th decades
  - 3 times more common in women
  - May be associated with radiation exposure
  - Tumor contains psammoma bodies, 50%
  - Metastasizes by lymphatic route (30% at time of diagnosis)
  - Multicentric in <sup>3</sup>20%, especially in children
  - Higher risk in patients with Hashimoto thyroiditis
- Follicular carcinoma
  - 10-20% of thyroid tumors
  - Peak incidence in 5th decade of life
  - Incidence has been decreasing because of the addition of dietary iodine.
  - Metastasizes by the hematogenous route
- Hürthle cell carcinoma (variant of follicular with poorer prognosis)
  - 2-3% of thyroid malignancies
  - Usually in patients >60 years old
  - No gender difference
  - Radioresistant

- Composed of distinct large eosinophilic cells with abundant cytoplasmic mitochondria
- Variant of follicular carcinoma with worse prognosis
- Medullary thyroid carcinoma (MCT)
  - Arises from parafollicular cells, C cells
  - Multiple endocrine neoplasia (MEN) syndromes (MEN2A, MEN2B, FMTC). Prevalence of MEN2 is 1:30,000.
  - MCT associated with MEN2B occur in childhood, those with MEN2A occur in young adults, and those with FMTC occur at middle age.
  - 3-4% of all thyroid tumors
  - 25-35% are associated with MEN syndromes (2A more common than 2B), which can be familial or sporadic.
  - Calcitonin is a chemical marker.
  - *RET* proto-oncogene mutation is screened; family members who carry the *RET* gene should consider early prophylactic thyroidectomy.
- Anaplastic carcinoma
  - 3% of thyroid tumors
  - Most aggressive form of thyroid neoplasia
  - More common in females
  - Usually in patients >60 years old
- Other: lymphoma, sarcoma, or metastatic (renal, breast, or lung)
- System(s) affected: endocrine/metabolic
- Synonym(s): follicular carcinoma of the thyroid; papillary carcinoma of the thyroid; Hürthle cell carcinoma of the thyroid; anaplastic cell carcinoma of the thyroid

### *Geriatric Considerations*

Risk of malignancy increases at >60 years old.

### *Pediatric Considerations*

- >60% of thyroid nodules are malignant.
- <2% of thyroid malignancies occur in children and adolescents.

# EPIDEMIOLOGY

## Incidence

- 12.9/100,000 per year in the United States
- Deaths: 0.5/100,000 per year in the United States
- In 2015, estimated 62,450 new cases and 1,950 deaths from thyroid cancer in the United States
- Predominant age: usually >40 years old
- Predominant sex: female > male (2.6:1) prevalence
- Lifetime risk of developing thyroid cancer is 1.1%
- In 2011, 566,708 patients living with thyroid cancer in the United States

## ETIOLOGY AND PATHOPHYSIOLOGY

Unknown

### Genetics

- Familial polyposis of the colon, Turcot syndrome, and Gardner syndrome with the *APC* gene (5q21)
- Medullary: autosomal dominant with MEN syndrome
- *BRAF* mutation (rare in children)
- *RET* oncogene (more common in children)

## RISK FACTORS

- Family history
- Neck irradiation (6 to 2,000 rads): papillary carcinoma
- Iodine deficiency: follicular carcinoma
- MEN2: medullary carcinoma; autosomal dominant
- Previous history of subtotal thyroidectomy for malignancy: anaplastic carcinoma
- Asian race
- Female gender

## GENERAL PREVENTION

- Physical exam in high-risk group
- Calcium infusion or pentagastrin stimulation test screening in high-risk MEN patients
- Screen for *RET* proto-oncogene in groups at-risk for MCT.

## COMMONLY ASSOCIATED CONDITIONS

Medullary carcinoma: pheochromocytoma, hyperparathyroidism, ganglioneuroma of the GI tract, neuromata of mucosal membranes

## DIAGNOSIS

### HISTORY

- Change in voice (hoarseness)
- Positive family history
- Neck mass
- Dysphagia
- Dyspnea
- Cough
- Difficulty swallowing

## PHYSICAL EXAM

- Neck mass: If fixed to surrounding tissue, this finding suggests advanced disease.
- Cervical adenopathy

## DIFFERENTIAL DIAGNOSIS

- Multinodular goiter
- Thyroid adenoma
- Thyroglossal duct cyst
- Thyroiditis
- Thyroid cyst
- Ectopic thyroid
- Dermoid cyst

## DIAGNOSTIC TESTS & INTERPRETATION

- Medullary carcinoma: calcitonin level (normal <30 pg/mL [300 ng/L]), pentagastrin stimulation test, and *RET* proto-oncogene
- Thyroglobulin (TG) level: postoperative tumor marker
- DNA content of tumors from biopsy specimen: Diploid content has a better prognosis.
- Thyroid function tests usually normal
- Thyroid scan: 12-15% of cold nodules are malignant; rate is higher in patients <40 years of age and those with microcalcifications on US.
- US: Solid mass and microcalcifications are more suspicious of malignancy.
- CT scan and MRI can be useful to evaluate large substernal masses and recurrent soft tissue masses.
- <sup>18</sup>F-FDG positron-emission tomographic scan can help if the cytology is inconclusive; helpful with recurrent disease when patient has a negative <sup>131</sup>I scan and an elevated TG level

### *Diagnostic Procedures/Other*

- Fine-needle aspiration (FNA)
- Surgical biopsy/excision
- Laryngoscopy if vocal cord paralysis is suspected.

### *Test Interpretation*

- Papillary: psammoma bodies, anaplastic epithelial papillae
- Follicular: anaplastic epithelial cords with follicles
- Hürthle cell: large eosinophilic cells with granular cytoplasm
- Medullary: large amounts of amyloid stroma
- Anaplastic: small cell and giant cell undifferentiated tumors

## **TREATMENT**

### *MEDICATION*

- Postoperatively, will require thyroid hormone replacement: Goal is to keep TSH <0.1 mU/L.
- Levothyroxine (T<sub>4</sub>, Synthroid) 100 to 200  $\mu$ g/day

- Liothyronine (T<sub>3</sub>, Cytomel) 50 to 100 &mgr;g/day

## GENERAL MEASURES

- Papillary/follicular: <sup>131</sup>I thyroid remnant ablation
- Medullary: Vandetanib has been tried in patients with advanced disease (1)[B].
- Anaplastic: Doxorubicin and cisplatin have achieved partial remission in some patients (2)[B].
- Recurrent tumor: Sorafenib has been used in patients with recurrent disease.

## ADDITIONAL THERAPIES

- External beam radiation for advanced disease
- <sup>131</sup>I is used in high-risk patients with papillary and follicular tumors. The role is to ablate remnant thyroid tissue to improve specificity of future TG assays (3)[C].

## SURGERY/OTHER PROCEDURES

- Papillary carcinoma: lobectomy with isthmectomy (if lesion <1 cm) or total thyroidectomy and removal of suspicious lymph nodes. Total thyroidectomy for tumors >1 cm (4)[B]
- Follicular carcinoma and Hÿrthle cell: total thyroidectomy and removal of suspicious lymph nodes
- Medullary carcinoma: total thyroidectomy with central node dissection; unilateral or bilateral modified radical neck dissection if lateral nodes are histologically positive
- Anaplastic carcinoma: aggressive en bloc thyroidectomy; tracheostomy often required; not responsive to <sup>131</sup>I

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- 10-30% of initially disease-free patients will develop recurrence and/or metastases. 80% recur in neck and 20% with distant metastases. Lung is most common site of distant metastases.
- Thyroid scan at 6 weeks and administration of <sup>131</sup>I for any visible uptake; any evidence of residual thyroid tissue (after total thyroidectomy) or lymph node disease noted on scan is

treated with radioactive iodine.

- At 6 months and then yearly, the patient should have a thyroid scan and chest x-ray.
- Papillary and follicular: a TG level should be done yearly. Recombinant human thyroid-stimulating hormone (rhTSH)-stimulated TG level may be more sensitive.
- Medullary: Calcitonin level should be done yearly with pentagastrin stimulation.
- The thyroid scan and TG level should be done with the patient in the hypothyroid state induced by 6-week withdrawal of levothyroxine or 2- to 3-week withdrawal of liothyronine.
- Decreased incidence of recurrence when TSH is suppressed.

## *DIET*

Avoid iodine deficiency.

## *PATIENT EDUCATION*

National Cancer Institute: (301) 496-5583; <http://www.cancer.gov>

## *PROGNOSIS*

- Taken together: 5-year survival of thyroid cancer is 97.8%.
- Favorable factors: female, multifocality, regional LN involvement
- Adverse factors: age >45 years, follicular histology, primary tumor >4 cm, extrathyroid extension, distant metastases
- Papillary carcinoma: 10-year overall survival is 93%; 30-year cancer-related death rate of 6%
- Follicular carcinoma: 10-year overall survival is 85%; histologically, microinvasive tumors parallel papillary tumor results, whereas grossly invasive tumors do far worse; 30-year cancer-related death rate of 15%
- Hÿrthle cell carcinoma: 93% 5-year survival rate and 83% survival rate overall; grossly invasive tumor survival <25%
- Medullary carcinoma: negative nodes, 90% 5-year survival rate and 85% 10-year survival rate; with positive nodes, 65% 5-year survival rate and 40% 10-year survival rate. Prognosis worse for MEN2B compared to MEN2A. Overall 10-year survival is 75%.
- Anaplastic carcinoma: survival unexpected. Longterm survivors should have original pathology reexamined.

## **COMPLICATIONS**

- Recurrence of tumor is 10-30%; 80% recur in neck, and 20% recur distally
- Hoarseness from tumor invasion or operative injury to recurrent laryngeal nerve
- Hypoparathyroidism from operative injury to parathyroid glands

**&NA;**

Multiple Endocrine Neoplasia (MEN) Syndromes

## Codes

**&NA;**

**ICD10**

C73 Malignant neoplasm of thyroid gland

## Clinical Pearls

**&NA;**

- Standard workup for a patient suspected of having a thyroid cancer is a physical exam, TSH level, neck US, and FNA.
- TG levels can be elevated in several thyroid disorders. Its usefulness comes once the diagnosis of cancer has been made. It serves as a better marker for recurrent disease.
- ÷ 2% of the normal population will have a positive <sup>18</sup>F-FDG positron-emission tomographic scan, so it is more useful for postresection follow-up.
- FNA results will be benign, malignant, indeterminate, or nondiagnostic. More helpful in planning initial surgical approach.

# Thyroiditis

Robert A. Baldor, MD, FAAFP

## BASICS

### DESCRIPTION

Inflammation of the thyroid gland that may be painful or painless

- Thyroiditis with thyroid pain
  - Subacute granulomatous thyroiditis (nonsuppurative thyroiditis, de Quervain thyroiditis, or giant cell thyroiditis): self-limited; viral URI prodrome, symptoms and signs of thyroid dysfunction (variable)
  - Infectious/suppurative thyroiditis
    - Bacterial, fungal, mycobacterial, or parasitic infection of the thyroid
    - Most commonly associated with *Streptococcus pyogenes*, *Staphylococcus aureus*, and *Streptococcus pneumoniae*
  - Radiation-induced thyroiditis: from radioactive iodine therapy (1%) or external irradiation for lymphoma and head/neck cancers
- Thyroiditis with no thyroid pain
  - Hashimoto (autoimmune) thyroiditis (chronic lymphocytic thyroiditis): most common etiology of chronic hypothyroidism; autoimmune disease; 90% of patients with high-serum antithyroid peroxidase (TPO) antibodies
  - Postpartum thyroiditis: episode of thyrotoxicosis, hypothyroidism, or thyrotoxicosis followed by hypothyroidism in the 1st year postpartum or after spontaneous/induced abortion in women who were without clinically evident thyroid disease before pregnancy
  - Painless (silent) thyroiditis (subacute lymphocytic thyroiditis): mild hyperthyroidism, small painless goiter, and no Graves ophthalmopathy/pretibial myxedema
  - Riedel (fibrous) thyroiditis: rare inflammatory process involving the thyroid and surrounding cervical tissues; associated with various forms of systemic fibrosis; presents as a firm mass in the thyroid commonly associated with compressive symptoms (dyspnea, dysphagia, hoarseness, and aphonia) caused by local infiltration of the advancing fibrotic process with

hypocalcemia and hypothyroidism

- Drug-induced thyroiditis: interferon- $\alpha$ , interleukin-2, amiodarone, or lithium

## **EPIDEMIOLOGY**

- Subacute granulomatous thyroiditis: most common cause of thyroid pain; peaks during summer; incidence: 3/100,000/year; female > male (4:1); peak age: 40 to 50 years
- Suppurative thyroiditis: commonly seen with preexisting thyroid disease/immunocompromise
- Hashimoto thyroiditis: peak age of onset, 30 to 50 years; can occur in children; primarily a disease of women; female > male (7:1)
- Postpartum thyroiditis: Female only; occurs within 12 months of pregnancy in 8-11% of pregnancies; occurs in 25% with type 1 diabetes mellitus; incidence is affected by genetic influences and iodine intake.
- Painless (silent) thyroiditis: female > male (4:1) with peak age 30 to 40 years; common in areas of iodine sufficiency
- Reidel thyroiditis: female > male (4:1); highest prevalence age 30 to 60 years

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Hashimoto disease: Antithyroid antibodies may be produced in response to an environmental antigen and cross-react with thyroid proteins (molecular mimicry). Precipitating factors include infection, stress, sex steroids, pregnancy, iodine intake, and radiation exposure.
- Subacute granulomatous thyroiditis: probably viral
- Postpartum thyroiditis: autoimmunity-induced discharge of preformed hormone from the thyroid
- Painless (silent) thyroiditis: autoimmune

### **Genetics**

Autoimmune thyroiditis is associated with the CT60 polymorphism of cytotoxic T-cell lymphocyte-associated antigen 4. Also associated with HLA-DR4, -DR5, and -DR6 in whites

## **RISK FACTORS**

- Hashimoto disease: family history of thyroid/autoimmune disease, personal history of autoimmune disease (type 1 diabetes, celiac disease), high iodine intake, cigarette smoking, selenium deficiency
- Subacute granulomatous thyroiditis: recent viral respiratory infection

- Suppurative thyroiditis: congenital abnormalities (persistent thyroglossal duct/piriform sinus fistula), greater age, immunosuppression
- Radiation-induced thyroiditis: high-dose irradiation, younger age, female sex, preexisting hypothyroidism
- Postpartum thyroiditis: smoking, history of spontaneous/induced abortion
- Painless (silent) thyroiditis: iodine-deficient areas

## GENERAL PREVENTION

Selenium may decrease inflammatory activity in pregnant women with autoimmune hypothyroidism and may reduce postpartum thyroiditis risk in those positive for TPO antibodies.

## COMMONLY ASSOCIATED CONDITIONS

Postpartum thyroiditis: family history of autoimmune thyroid disease; HLA-DRB, -DR4, and -DR5

## DIAGNOSIS

### HISTORY

- Hypothyroid symptoms (e.g., constipation, heavy menstrual bleeding, fatigue, weakness, dry skin, hair loss, cold intolerance)
- Hyperthyroid symptoms (e.g., irritability, heat intolerance, increased sweating, palpitations, loose stools, disturbed sleep, and lid retraction)
- Subacute granulomatous thyroiditis: Sudden/gradual onset, with preceding upper respiratory infection/viral illness (fever, fatigue, malaise, anorexia, and myalgia are common); pain may be limited to thyroid region or radiate to upper neck, jaw, throat, or ears.
- Classic triphasic course (thyrotoxic, hypothyroid, recovery) but variable in the following: subacute, silent, and postpartum thyroiditis (1)[C]

## PHYSICAL EXAM

- Examine thyroid size, symmetry, and nodules.
  - Hashimoto disease: 90% have a symmetric, diffusely enlarged, painless gland, with a firm, pebbly texture; 10% have thyroid atrophy.
  - Postpartum thyroiditis: painless, small, nontender, firm goiter (2 to 6 months after delivery)
  - Reidel thyroiditis: rock-hard, wood-like, fixed, painless goiter, often accompanied by symptoms of esophageal/tracheal compression (stridor, dyspnea, a suffocating feeling,

dysphagia, and hoarseness)

- Signs of hypothyroid: delayed relaxation phase of deep tendon reflexes, nonpitting edema, dry skin, alopecia, bradycardia
- Signs of hyperthyroid: moist palms, hyperreflexia, tachycardia/atrial fibrillation

## *DIFFERENTIAL DIAGNOSIS*

Simple goiter; iodine-deficient/lithium-induced goiter; Graves disease; lymphoma; acute infectious thyroiditis; oropharynx and trachea infections; thyroid cancer; amiodarone; contrast dye; amyloid

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Thyroid-stimulating hormone (TSH), anti-TPO antibodies
- Hashimoto disease
  - High titers of anti-TPO antibodies
  - New subtype: IgG4 thyroiditis, which is histopathologically characterized by lymphoplasmacytic infiltration, fibrosis, increased numbers of IgG4-positive plasma cells, and high serum IgG4 levels; more closely associated with rapid progress, subclinical hypothyroidism, higher levels of circulating antibodies, and more diffuse low echogenicity (2)[C]
- Subacute granulomatous thyroiditis
  - High  $T_4$ ,  $T_3$ ; low TSH during early stages and elevated later; TSH varies with phase (1)[C].
  - High thyroglobulin; normal levels of anti-TPO and antithyroglobulin antibodies (present in 25%, usually low titers)
  - Elevated erythrocyte sedimentation rate (ESR) (usually  $>50$  mm/hr) and C-reactive protein; mild anemia and slight leukocytosis; LFTs are frequently abnormal during initial hyperthyroid phase and resolve over 1 to 2 months.
- Suppurative thyroiditis
  - In the absence of preexisting thyroid disease, thyroid function is normal but hyper-/hypothyroidism may occur.
  - Elevated ESR and WBC with marked increase in left shift
  - Fine-needle aspiration (FNA) of the lesion with Gram stain and culture is the most useful diagnostic test.
- Postpartum thyroiditis (3)[B]

- Anti-TPO antibody positivity is the most useful marker for the prediction of postpartum thyroid dysfunction.
- Women known to be anti-TPO-Ab + should have TSH measured at 6 to 12 weeks' gestation and at 6 months postpartum or as clinically indicated.
- Thyrotoxic phase occurs 1 and 6 months postpartum (most commonly at 3 months) and usually lasts only 1 to 2 months.
- Hypothyroidism occurs between 3 and 8 months (most commonly at 6 months).
- Most patients (80%) have normal thyroid function at 1 year; 30-50% of patients develop permanent hypothyroidism within 9 years.
- High thyroglobulin, normal ESR

P.1037

- Painless (silent) thyroiditis
  - Hyperthyroid state in 5-20%: averages 3 to 4 months, and total duration of illness is <1 year, followed by hypothyroidism and then a return to normal state; some have primary/subclinical hypothyroidism.
  - ÷ 50% have anti-TPO antibodies (1)[C].
- Reidel thyroiditis (4)[C]
  - Hypothyroidism due to extensive replacement of the gland by scar tissue. Anti-TPO antibodies are present in 2/3 of patients along with low radioactive iodine uptake (RAIU).
- Drug-induced thyroiditis
  - Hyper-/hypothyroidism, low RAIU, and variable presence of anti-TPO antibodies
- US: shows variable heterogeneous texture, hypoechogenic in subacute, painless (silent), and postpartum thyroiditis
- Thyroid RAIU scan: decreased in all forms of thyroiditis but not helpful in establishing diagnosis of Hashimoto disease. High RAIU in hashitoxicosis, Graves disease
- Random urine iodine measurement may be helpful to distinguish from other causes of low RAIU.
  - Urine iodine <500  $\mu\text{g}/\text{L}$  (subacute granulomatous thyroiditis)
  - Urine iodine >1,000  $\mu\text{g}/\text{L}$  (in patients with exposure to excess exogenous iodine/radiocontrast material)

## Diagnostic Procedures/Other

- Hashimoto with a dominant nodule should have FNA to rule out thyroid carcinoma.
- Open biopsy is necessary for a definitive diagnosis of Reidel thyroiditis.

## *Test Interpretation*

- Hashimoto disease: lymphocytic infiltration with formation of Askanazy (Hürthle) cells, oxyphilic changes in follicular cells, fibrosis, thyroid atrophy
- Subacute granulomatous thyroiditis: giant cells, mononuclear cell (granulomatous) infiltrate
- Postpartum thyroiditis: lymphocytic infiltration, occasional germinal centers, disruption and collapse of thyroid follicles
- Painless (silent) thyroiditis: lymphocytic infiltration, but without fibrosis, Askanazy cells, and extensive lymphoid follicle formation

## **TREATMENT**

### *GENERAL MEASURES*

Analgesics for pain; corticosteroids for severe granulomatous thyroiditis

### *MEDICATION*

- Hashimoto disease (2)[C]
  - If hypothyroid/goitrous: levothyroxine (1.7  $\mu\text{g}/\text{kg}/\text{day}$  for adults <50 years of age). If no cardiac complications and no adrenal insufficiency, 1/2 replacement dose and increase to full replacement in 10 days.
    - If >50 years of age or heart disease and/or adrenal insufficiency, begin with 25  $\mu\text{g}/\text{day}$  and titrate to TSH of lower limit normal range.
- If thyrotoxic and symptomatic: propylthiouracil and propranolol
- An elevated TSH level in a woman who is pregnant or attempting to become pregnant is an indication for thyroid replacement.
- Subacute granulomatous thyroiditis
  - Anti-inflammatory agents for 2 to 8 weeks (NSAIDs or aspirin)
  - Pain with no improvement in 2 to 3 days after NSAID use: Prednisone 40 mg/day; should result in pain relief in 1 to 2 days; if not, question diagnosis.
  - Severe pain: prednisone 40 to 60 mg/day discontinued over 4 to 6 weeks. If pain recurs,

increase dose for several weeks and then taper.

- Symptomatic hyperthyroidism:  $\beta$ -blockers while thyrotoxic (propranolol 40 to 120 mg/day)
- Symptomatic hypothyroid phase: Levothyroxine, as mentioned earlier, target TSH in the normal range.
- Suppurative thyroiditis
  - Parenteral empiric, broad-spectrum antibiotics, and surgical drainage
- Painless (silent) thyroiditis
  - No treatment needed.
  - If symptomatic during hyperthyroid state, treat with  $\beta$ -blocker (propranolol 40 to 120 mg/day).
  - Prednisone shortens the period of hyperthyroidism. Monitor TSH every 4 to 8 weeks to confirm resolution.
  - Treat hypothyroid symptoms and asymptomatic patients with TSH >10 mU/L with levothyroxine (50 to 100  $\mu$ g/day), to be discontinued after 3 to 6 months.
- Postpartum thyroiditis (5)[C]
  - Treat symptomatic hyper-/hypothyroid state. Most do not need treatment.
  - Caution in breastfeeding mothers because  $\beta$ -blockers are secreted into breast milk.
  - For symptomatic hypothyroidism, treat with levothyroxine. Otherwise, remonitor in 4 to 8 weeks. Taper replacement hormone after 6 months if thyroid function has normalized.
- Reidel thyroiditis (4)[C]
  - Corticosteroids in early stages but controversial thereafter. Prednisone 10 to 20 mg/day for 4 to 6 months, possibly continued thereafter if effective
  - Long-term anti-inflammatory medications to arrest progression and maintain a symptom-free course
  - Tamoxifen 10 to 20 mg twice daily as monotherapy or in conjunction with prednisone reduces mass size and clinical symptoms.
  - Methotrexate is used with some success.
  - Reduction of goiter seen with a combination of mycophenolate mofetil (1 g BID) and 100 mg/day prednisone
  - Debulking surgery is limited to isthmusectomy to relieve constrictive pressure when total

thyroidectomy is not possible.

- Drug-induced thyroiditis
  - Discontinue offending drug.

## ***SURGERY/OTHER PROCEDURES***

Enlarged painful thyroid or tracheal compression

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### **Patient Monitoring**

- Hashimoto disease: Repeat thyroid function tests every 3 to 12 months.
- Subacute granulomatous thyroiditis: Repeat thyroid function tests every 3 to 6 weeks until euthyroid, then every 6 to 12 months.
- Postpartum thyroiditis: Check TSH annually.
- Reidel thyroiditis: CT of cervical mediastinal region is recommended.
- TSH every 6 months in patients on amiodarone

#### ***Pregnancy Considerations***

- Avoid radioisotope scanning if possible.
- Keep TSH maximally suppressed.
- If using RAIU scan, discard breast milk for 2 days because RAI is secreted in breast milk.

### ***PROGNOSIS***

- Hashimoto disease: persistent goiter; eventual thyroid failure
- Subacute granulomatous thyroiditis: 5-15% hypothyroid beyond a year: Some with eventual return to normal; remission may be slower in the elderly; recurrence rate: 1-4% after a year
- Painless (silent) thyroiditis: 10-20% hypothyroid beyond a year; recurrence rate 5-10% (much higher in Japan)
- Postpartum thyroiditis: 15-50% hypothyroid beyond a year; women may be euthyroid/continue to be hypothyroid at the end of 1st postpartum year. 70% recurrence rate in subsequent pregnancies; substantial risk exists for later development of hypothyroidism/goiter.

## Codes

&NA;

### ICD10

- E06.9 Thyroiditis, unspecified

- E06.1 Subacute thyroiditis
- E06.0 Acute thyroiditis

## Clinical Pearls

**&NA;**

- TSH elevation above the normal range indicates a hypothyroid state; suppressed TSH indicates hyperthyroid state. Follow up with free T<sub>3</sub>/T<sub>4</sub> determination.
- Follow patients on thyroid replacement with periodic TSH level.

# Tinea (Capitis, Corporis, Cruris)

Elisabeth L. Backer, MD

## BASICS

### DESCRIPTION

- Superficial fungal infections of the skin/scalp; various forms of dermatophytosis; the names relate to the particular area affected (1).
  - Tinea cruris: infection of crural fold and gluteal cleft
  - Tinea corporis: infection involving the face, trunk, and/or extremities; often presents with ringshaped lesions, hence the misnomer *ringworm*.
  - Tinea capitis: infection of the scalp and hair; affected areas of the scalp can show characteristic black dots resulting from broken hairs.
- Dermatophytes have the ability to subsist on protein, namely keratin.
- They cause disease in keratin-rich structures such as skin, nails, and hair.
- Infections result from contact with infected persons/animals
  - Zoophilic infections are acquired from animals.
  - Anthropophilic infections are acquired from personal contact (e.g., wrestling) or fomites.
  - Geophile infections are acquired from the soil.
- System(s) affected: skin; exocrine
- Synonym(s): jock itch; ringworm

### EPIDEMIOLOGY

#### Incidence

- Tinea cruris
  - Predominant age: any age; rare in children
  - Predominant sex: male > female
- Tinea corporis

- Predominant age: all ages
- Predominant sex: male = female
- Tinea capitis
  - Predominant age: 3 to 9 years; almost always occurs in young children
  - Predominant sex: male = female

## *Prevalence*

Common worldwide

## *Pediatric Considerations*

- Tinea cruris is rare prior to puberty.
- Tinea capitis is common in young children.

## *Geriatric Considerations*

Tinea cruris is more common in the geriatric population due to an increase in risk factors.

## *Pregnancy Considerations*

Tinea cruris and capitis are rare in pregnancy.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

Superficial fungal infection of skin/scalp

- Tinea cruris: Source of infection is usually the patient's own tinea pedis, with agent being transferred from the foot to the groin via the underwear when dressing; most common causative dermatophyte is *Trichophyton rubrum*; rare cases caused by *Epidermophyton floccosum* and *T. mentagrophytes*.
- Tinea corporis: most commonly caused by *T. rubrum*; *T. tonsurans* most often found in patients with tinea gladiatorum.
- Tinea capitis: *T. tonsurans* found in 90% and *Microsporum* sp. in 10% of patients

## *Genetics*

Evidence suggests a genetic susceptibility in certain individuals.

## **RISK FACTORS**

- Warm climates; summer months and/or copious sweating; wearing wet clothing/multiple layers (tinea cruris)
- Daycare centers/schools/confined quarters (tinea corporis and capitis)
- Depression of cell-mediated immune response (e.g., individuals with atopy or AIDS)
- Obesity (tinea cruris and corporis)
- Direct contact with an active lesion on a human, an animal, or rarely, from soil; working with animals (tinea corporis)

## GENERAL PREVENTION

- Avoidance of risk factors, such as contact with suspicious lesions
- Fluconazole or itraconazole may be useful in wrestlers to prevent outbreaks during competitive season.

## COMMONLY ASSOCIATED CONDITIONS

Tinea pedis, tinea barbae, tinea manus

## DIAGNOSIS

### HISTORY

- Lesions range from asymptomatic to pruritic.
- In tinea cruris, acute inflammation may result from wearing occlusive clothing; chronic scratching may result in an eczematous appearance.
- Previous application of topical steroids, especially in tinea cruris and corporis, may alter the overall appearance causing a more extensive eruption with irregular borders and erythematous papules. This modified form is called *tinea incognito*.

## PHYSICAL EXAM

- Tinea cruris: well-margined, erythematous, halfmoon-shaped plaques in crural folds that spread to upper thighs; advancing border is well defined, often with fine scaling and sometimes vesicular eruptions. Lesions are usually bilateral and do not include scrotum/penis (unlike with *Candida* infections) but may migrate to perineum, perianal area, and gluteal cleft and onto the buttocks in chronic/progressive cases. The area may be hyperpigmented on resolution.
- Tinea corporis: scaling, pruritic plaques characterized by a sharply defined annular pattern with

peripheral activity and central clearing (ring-shaped lesions); papules and occasionally pustules/vesicles present at border and, less commonly, in center.

- Tinea capitis: commonly begins with round patches of scale (alopecia less common). In its later stages, the infection frequently takes on patterns of chronic scaling with either little/marked inflammation or alopecia. Less often, patients will present with multiple patches of alopecia and the characteristic black-dot appearance of broken hairs. Extreme inflammation results in kerion formation (exudative, pustular nodulation).

## ***DIFFERENTIAL DIAGNOSIS***

- Tinea cruris
  - Intertrigo: inflammatory process of moist-opposed skin folds, often including infection with bacteria, yeast, and fungi; painful longitudinal fissures may occur in skin folds.
  - Erythrasma: diffuse brown, scaly, noninflammatory plaque with irregular borders, often involving groin; caused by bacterial infection with *Corynebacterium minutissimum*; fluoresces coral red with Wood lamp
  - Seborrheic dermatitis of groin
  - Psoriasis of groin (Inverse psoriasis)
  - Candidiasis of groin (typically involves the scrotum)
  - Acanthosis nigricans
- Tinea capitis
  - Psoriasis
  - Seborrheic dermatitis
  - Pyoderma
  - Alopecia areata and trichotillomania
  - Aplasia cutis congenital
- Tinea corporis
  - Pityriasis rosea
  - Eczema (nummular)
  - Contact dermatitis
  - Syphilis
  - Psoriasis

- Seborrheic dermatitis
- Subacute systemic lupus erythematosus (SLE)
- Erythema annulare centrifugum
- Erythema multiforme; erythema migrans
- Impetigo circinatum
- Granuloma annulare

## DIAGNOSTIC TESTS & INTERPRETATION

Wood lamp exam reveals no fluorescence in most cases (*Trichophyton* sp.); 10% of infections, those caused by *T. rubrum* will fluoresce with a green light.

### Initial Tests (lab, imaging)

- Potassium hydroxide (KOH) preparation of skin scrapings from dermatophyte leading border shows characteristic translucent, branching, rod-shaped hyphae.
- Arthrospores can be visualized within hair shafts. Spores and/or hyphae may be seen on KOH exam.

### Follow-Up Tests & Special Considerations

- Reevaluate to assess response, especially in resistant/extensive cases
- Fungal culture using Sabouraud dextrose agar/dermatophyte test medium

---

P.1039

## Test Interpretation

- Skin scrapings show fungal hyphae in epidermis.
- Arthrospores found in hair shafts; spores and/or hyphae seen on KOH exam.

## TREATMENT

### GENERAL MEASURES

- Careful handwashing and personal hygiene; laundering of towels/clothing of affected individual; no sharing of towels/clothes/headgear
- Evaluate other family members, close contacts, or household pets.

Avoid predisposing conditions such as hot baths and tight-fitting clothing (boxer shorts are better than briefs).

- Keep area as dry as possible (talcum/powders may be beneficial).
- Itching can be alleviated by OTC preparations such as Sarna or Prax.
- Topical steroid preparations should be avoided (see *Tinea Incognita*), unless absolutely needed to control itching and only after definitive diagnosis and initiation of antifungal treatment.
- Nystatin should be avoided in tinea infections but is indicated for cutaneous candidal infections.
- Avoid contact sports (e.g., wrestling) temporarily while starting treatment.

## MEDICATION

### First Line

- Tinea cruris/corporis (2)[C]
  - Topical azole antifungal compounds
    - Terbinafine 1% (Lamisil): OTC inexpensive and effective compound; can be applied once or BID for 1 to 2 weeks
    - Econazole 1% (Spectazole), ketoconazole (Nizoral): usually applied BID for 2 to 3 weeks
    - Butenafine 1% (Mentax): applied once daily for 2 weeks; also very effective. To prevent relapse, use for 1 week after resolution.
- Tinea capitis (3)[A]
  - PO griseofulvin for *Trichophyton* and *Microsporum* sp.; micro-sized preparation available; dosage 10 to 20 mg/kg/day (max 1,000 mg); taken BID or as a single dose daily for 6 to 12 weeks
  - PO terbinafine can be used for *Trichophyton* sp. at 62.5 mg/day in patients weighing 10 to 20 kg; 125 mg/day if weight 20 to 40 kg; 250 mg/day if weight >40 kg; use for 4 to 6 weeks.
  - PO itraconazole can be used for *Microsporum* sp. and matches griseofulvin efficacy while being better tolerated. Dosage of 3 to 5 mg/kg/day, but most studies have used 100 mg/day for 6 weeks in children >2 years of age.

### Second Line

## Tinea cruris/corporis

- Oral antifungal agents are effective but not indicated in uncomplicated tinea cruris/corporis cases. They can be used for resistant and extensive infections or if the patient is immunocompromised. If topical therapy fails, consider possible oral therapy. Griseofulvin can be given 500 mg/day for 1 to 2 weeks.
- The following oral regimens have been reported in medical literature as being effective but currently are not specifically approved by FDA for tinea cruris:
  - PO terbinafine (Lamisil): 250 mg/day for 1 week
  - PO itraconazole (Sporanox): 100 mg BID once and repeated 1 week later
  - PO fluconazole (Diflucan): 150 mg once per week for 4 weeks
- Topical terbinafine 1% solution has been studied recently and appears effective as a once-daily application for 1 week.
- Oral antifungals have many interactions including warfarin, OCPs, and alcohol; advise checking for drug interactions prior to use; contraindicated in pregnancy. Monitor for liver toxicity when using oral antifungals.

## *ISSUES FOR REFERRAL*

Refer if disease is nonresponsive/resistant, especially in immunocompromised host.

## *ADDITIONAL THERAPIES*

Treatment of secondary bacterial infections

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

Reevaluate response to treatment.

## *Patient Monitoring*

Liver function testing prior to therapy and at regular intervals during course of therapy for patients requiring oral terbinafine, fluconazole, itraconazole, and griseofulvin.

## *PATIENT EDUCATION*

Explain the causative agents, predisposing factors, and prevention measures.

## PROGNOSIS

- Excellent prognosis for cure with therapy in tinea cruris and corporis.
- In tinea capitis, lesions will heal spontaneously in 6 months without treatment but scarring is more likely.

## COMPLICATIONS

- Secondary bacterial infection
- Generalized, invasive dermatophyte infection
- Secondary eruptions called dermatophytid reactions may occur at distant sites.

## Codes

**&NA;**

### ICD10

- B35.0 Tinea barbae and tinea capitis
- B35.4 Tinea corporis
- B35.6 Tinea cruris

## Clinical Pearls

**&NA;**

- Tinea corporis is characterized by scaly plaque, with peripheral activity and central clearing.
- Tinea cruris is characterized by erythematous plaque in crural folds usually sparing the scrotum. Treatment of concomitant tinea pedis is advised.
- Tinea capitis is a fungal infection of the scalp affecting hair growth. Topical therapy is ineffective for this infection.

# Tinea Pedis

Elisabeth L. Backer, MD

## BASICS

### DESCRIPTION

- Superficial infection of the feet caused by dermatophytes
- Most common dermatophyte infection encountered in clinical practice
- Often accompanied by tinea manuum, tinea unguium, and tinea cruris
- Two clinical forms: acute and chronic; both are contagious
- System(s) affected: skin/exocrine
- Synonym(s): athlete's foot

### EPIDEMIOLOGY

- Predominant age: 20 to 50 years, although can occur at any age (1)[C]
- Predominant gender: male > female

### Prevalence

4% of population

### Pediatric Considerations

Rare in younger children; common in teens

### Geriatric Considerations

Elderly are more susceptible to outbreaks because of immunocompromise and impaired perfusion of distal extremities.

### ETIOLOGY AND PATHOPHYSIOLOGY

Superficial infection caused by dermatophytes that thrive only in nonviable keratinized tissue.

- *Trichophyton mentagrophytes* (acute)
- *Trichophyton rubrum* (chronic)

- *Trichophyton tonsurans*
- *Epidermophyton floccosum*

## Genetics

No known genetic pattern

## RISK FACTORS

- Hot, humid weather
- Sweating
- Occlusive/tight-fitting footwear
- Immunosuppression
- Prolonged application of topical steroids

## GENERAL PREVENTION

- Good personal hygiene
- Wearing rubber or wooden sandals in community showers, bathing places, locker rooms
- Careful drying between toes after showering or bathing; blow-drying feet with hair dryer may be more effective than drying with towel.
- Changing socks and shoes frequently
- Applying drying or dusting powder
- Applying topical antiperspirants
- Putting on socks before underwear to prevent infection from spreading to groin

## COMMONLY ASSOCIATED CONDITIONS

- Hyperhidrosis
- Onychomycosis
- Tinea manuum/unguium/cruris/corporis

## DIAGNOSIS

## HISTORY

Itchy, scaly rash on foot, usually between toes; may progress to fissuring/maceration in toe web spaces.

- May be associated with onychomycosis and other tinea infections

## PHYSICAL EXAM

- Acute form: self-limited, intermittent, recurrent; scaling, thickening, and fissuring of sole and heel; scaling or fissuring of toe webs; or pruritic vesicular/bullous lesions between toes or on soles
- Chronic form: most common; slowly progressive, pruritic erythematous erosion/scales between toes, in digital interspaces; extension onto soles, sides/dorsum of feet (moccasin distribution); if untreated, may persist indefinitely
- Other features: strong odor, hyperkeratosis, maceration, ulceration
- Tinea pedis may occur unilateral or bilateral.
- Secondary eruptions called dermatophytid reactions may occur at distant sites.

## DIFFERENTIAL DIAGNOSIS

- Interdigital type: erythrasma, impetigo, pitted keratolysis, candidal intertrigo
- Moccasin type: psoriasis vulgaris, eczematous dermatitis, pitted keratolysis
- Inflammatory/bullous type: impetigo, allergic contact dermatitis, dyshidrotic eczema (negative KOH examination of scrapings), bullous disease

## DIAGNOSTIC TESTS & INTERPRETATION

Wood lamp exam will not fluoresce unless complicated by another fungus, which is uncommon:

*Malassezia furfur* (yellow to white), *Corynebacterium* (red), or *Microsporum* (blue-green).

### Initial Tests (lab, imaging)

Testing is not needed in typical presentation.

- Direct microscopic exam (potassium hydroxide) of scrapings of the lesions
- Culture (Sabouraud medium)

### Test Interpretation

- Potassium hydroxide preparation: septate and branched mycelia
- Culture: dermatophyte

## TREATMENT

Treatment is generally with topical antifungal medications for up to 4 weeks and is more effective than placebo:

- Acute treatment
  - Aluminum acetate soak (Burow solution; Domeboro, one pack to one quart warm water) to decrease itching and acute eczematous reaction
  - Antifungal cream of choice BID after soaks
- Chronic treatment:
  - Antifungal creams BID, continuing for 3 days after the rash is resolved: terbinafine 1% (possibly most effective topical), clotrimazole 1%, econazole 1%, ketoconazole 2%, tolnaftate 1%, etc. (2)[A]
  - May try systemic antifungal therapy; see below (consider if concomitant onychomycosis or after failed topical treatment)

## GENERAL MEASURES

- Soak with aluminum chloride 30% or aluminum subacetate for 20 minutes BID.
- Careful removal of dead/thickened skin after soaking or bathing
- Treatment of shoes with antifungal powders
- Avoidance of occlusive footwear
- Chronic or extensive disease or nail involvement requires oral antifungal medication and systemic therapy.

## MEDICATION

*For use when topical therapy has failed*

### *First Line*

- Systemic antifungals (3)[A]:
  - Itraconazole (Sporanox): 200 mg PO BID for 7 days (cure rate >90%)
  - Terbinafine (Lamisil): 250 mg/day PO for 14 days
- If concomitant onychomycosis:

- Itraconazole: 200 mg PO BID for first week of month for 3 months. Liver function testing is recommended.
- Terbinafine: 250 mg/day PO for 12 weeks, or pulse dosing: 500 mg/day PO for first week of month for 3 months. Not recommended if creatinine clearance is <50 mL/min.
- Pediatric dosing options:
  - Griseofulvin: 10 to 15 mg/kg/day or divided
  - Terbinafine:
    - 10 to 20 kg: 62.5 mg/day
    - 20 to 40 kg: 125 mg/day
    - >40 kg: 250 mg/day
- Itraconazole: 5 mg/kg/day
- Fluconazole: 6 mg/kg/week
- Contraindications: itraconazole, pregnancy Category C

---

P.1041

- Precautions: All systemic antifungal drugs may have potential hepatotoxicity.
- Significant possible interactions: Itraconazole requires gastric acid for absorption; effectiveness is reduced with antacids, H<sub>2</sub> blockers, proton pump inhibitors, etc. Take with acidic beverage such as soda if on antacids.

## *Second Line*

- Systemic antifungals: griseofulvin 250 to 500 mg of microsize BID daily for 21 days
- Contraindications (griseofulvin):
  - Patients with porphyria, hepatocellular failure
  - Patients with history of hypersensitivity to griseofulvin
- Precautions (griseofulvin):
  - Should be used only in severe cases
  - Periodic monitoring of organ-system functioning, including renal, hepatic, and hematopoietic
  - Possible photosensitivity reactions
  - Lupus erythematosus, lupus-like syndromes, or exacerbation of existing lupus erythematosus has been reported.

- Significant possible interactions (griseofulvin):
  - Decreases activity of warfarin-type anticoagulants
  - Barbiturates usually depress griseofulvin activity.
  - May potentiate effect of alcohol, producing tachycardia and flush

## *ISSUES FOR REFERRAL*

If extensive or resistant disease, especially in immunocompromised host

## *ADDITIONAL THERAPIES*

- Treatment of secondary bacterial infections
- Treatment of eczematoid changes

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

Avoid sweating feet.

## *Patient Monitoring*

Evaluate for response, recognizing that infections may be chronic/recurrent.

## *DIET*

No restrictions

## *PATIENT EDUCATION*

See "General Prevention."

## *PROGNOSIS*

- Control but not complete cure
- Infections tend to be chronic with exacerbations (e.g., in hot weather).
- Personal hygiene and preventive measures such as open-toed sandals, careful drying, and frequent sock changes are essential.

## **COMPLICATIONS**

- Secondary bacterial infections (common portal of entry for streptococcal

infections, producing lymphangitis/cellulitis of lower extremity)

- Eczematoid changes

Dermatitis, Contact; Dyshidrosis

## Codes

&NA;

ICD10

B35.3 Tinea pedis

## Clinical Pearls

**&NA;**

- Treatment is generally with topical antifungal medications for up to 4 weeks.
- Tinea pedis is often recurrent/chronic in nature.
- Careful drying between toes after showering or bathing helps prevent recurrences. (Blow drying feet with hair dryer may be more effective than drying with towel.)
- Socks should be changed frequently. Put on socks before underwear to prevent infection from spreading to groin (tinea cruris).
- Dusting and drying powders (containing antifungal agents) may prevent recurrences.

# Tinea Versicolor

Elisabeth L. Backer, MD

## BASICS

### DESCRIPTION

- Rash due to a common superficial mycosis with a variety of colors and changing shades of color, predominantly present on trunk and proximal upper extremities; macules are usually hypopigmented, light brown, or salmon-colored; fine scale is often apparent. It is not a dermatophyte infection.
- System(s) affected: skin/exocrine
- Synonym(s): pityriasis versicolor

### EPIDEMIOLOGY

#### Incidence

- Common, occurs worldwide, especially in tropical climates, where prevalence can reach 50%
- Predominant age: teenagers and young adults
- Predominant sex: male = female

#### Pediatric Considerations

Usually occurs after puberty (except in tropical areas); facial lesions are more common in children.

#### Geriatric Considerations

Not common in the geriatric population

### ETIOLOGY AND PATHOPHYSIOLOGY

Inhibition of pigment synthesis in epidermal melanocytes, leading to hypomelanosis; in the hyperpigmented type, the melanosomes are large and heavily melanized (1).

- Saprophytic yeast: *Pityrosporum orbiculare* (also known as *P. ovale*, *Malassezia furfur*, or *M. ovalis*), which is a known colonizer of all humans

- Development of clinical disease associated with transformation of *Malassezia* from yeast cells to pathogenic mycelial form due to host and/or external factors.
- Not linked to poor hygiene

## Genetics

Genetic predisposition may exist.

## RISK FACTORS

- Hot, humid weather
- Use of topical skin oils
- Hyperhidrosis
- HIV infection/immunosuppression
- High cortisol levels (Cushing, prolonged steroid administration)
- Pregnancy
- Malnutrition
- Oral contraceptives

## GENERAL PREVENTION

- Recheck and treat again each spring prior to tanning season.
- Avoid skin oils.

## DIAGNOSIS

### HISTORY

- Asymptomatic scaling macules on trunk
- Possible mild pruritus
- More prominent in summer
- Sun tanning accentuates lesions because infected areas do not tan.
- Periodic recurrences are common.

## PHYSICAL EXAM

- *Versicolor* refers to the variety and changing shades of colors. Color variations can exist between individuals and also between lesions.

- Sun-exposed areas: Lesions are usually white/hypopigmented.
- Covered areas: Lesions are often brown or salmon-colored.
- Distribution (sebum-rich areas): chest, shoulders, back (also face and intertriginous areas)
  - Face is more likely to be involved in children.
- Appearance: small individual macules that frequently coalesce
- Scale: fine, more visible with scraping

## ***DIFFERENTIAL DIAGNOSIS***

Other skin diseases with discolored macules and plaques, including the following:

- Pityriasis alba/rosea (Christmas tree-like distribution visible in *P. rosea*)
- Vitiligo (presents without scaling)
- Seborrheic dermatitis (more erythematous; thicker scale)
- Nummular eczema
- Secondary syphilis
- Erythrasma
- Mycosis fungoides

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Wood lamp: yellow to yellow-green fluorescence or pigment changes

### ***Initial Tests (lab, imaging)***

- Direct microscopy of scales with 10% potassium hydroxide (KOH) preparation to visualize hyphae and spores (spaghetti and meatballs pattern)
- Routine lab tests are usually not necessary.
- Fungal culture is not useful.

### ***Test Interpretation***

- Short, stubby, or Y-shaped hyphae
- Small, round spores in clusters on hyphae

## TREATMENT

### GENERAL MEASURES

- Apply prescribed topical medications to affected skin with cotton balls.
- Pigmentation may take months to fade or fill in.
- Repeat treatment each spring prior to sun exposure; some may require repeated treatment during the summer as prophylaxis.
- Patients who fail topical treatment can be treated with an oral/systemic medication.

### MEDICATION

Topical antifungal therapy is the treatment of choice in limited disease. Evidence is generally of poor quality, but data suggest that longer durations of treatment and higher concentrations of active agents produce greater cure rates (2)[A].

#### *First Line*

- Ketoconazole 2% shampoo applied to damp skin and left on for 5 minutes for 1 to 3 days *or*
- Selenium sulfide shampoo 2.5% (Selsun):
  - Allowed to dry for 10 minutes prior to showering: daily for 1 week *or*
  - Allowed to remain on body for 12 to 24 hours prior to showering: once a week for 4 weeks *or*

---

P.1043

- Clotrimazole 1% topical (Lotrimin) BID for 2 to 4 weeks *or*
- Miconazole 2% (Micatin, Monistat) BID for 2 to 4 weeks *or*
- Ketoconazole 2% (Nizoral) cream BID for 2 to 4 weeks *or*
- Terbinafine (Lamisil) 1% solution BID for 1 week *or*
- Terbinafine (Lamisil Derm Gel) once daily for 1 week
- Cure rates of topical antiyeast preparations typically 70-80%; healing continues after active treatment. Resumption of even pigmentation may take months.
- Contraindications: Ketoconazole is contraindicated in pregnancy.
- Newer preparations: 2.25% selenium sulfide foam; ketoconazole 2% gel

## *Second Line*

- Use for extensive disease or nonresponders
- Oral fluconazole 300 mg once weekly for 2 weeks (3)[A]
- Itraconazole 200 mg/day PO for 1 week; cure rate >90% (3)[A]
- Oral ketoconazole is no longer recommended by FDA due to risks of hepatotoxicity, adrenal insufficiency, and drug-drug interactions.
- Oral terbinafine or griseofulvin is not effective.
- Pramiconazole has been studied but is not yet available for clinical use.

## *ISSUES FOR REFERRAL*

- If resistant to treatment
- If extensive disease occurs in immunocompromised host

## **ONGOING CARE**

- Ketoconazole 2% or selenium sulfide 2.5% shampoo can be used weekly for maintenance or monthly for prophylaxis.
- Itraconazole 400 mg once monthly during the warmer months of the year can also reduce recurrences.

## *FOLLOW-UP RECOMMENDATIONS*

Warn patients that whiteness will remain for several months after treatment.

### *Patient Monitoring*

- Recheck and treat again each spring prior to tanning season.
- Failure to respond should prompt reassessment or dermatology referral.
- Resistance to treatment, frequent recurrences, or widespread disease may point to immunodeficiency.

## *PATIENT EDUCATION*

For patient education materials favorably reviewed on this topic, contact American Academy of Dermatology, 930 N. Meacham Road, P.O. Box 4014, Schaumburg, IL 60168-4014; (708) 330-0230.

## PROGNOSIS

- Duration of lesions months/years
- Recurs almost routinely because this yeast is a known human colonizer
- Pigmentary changes may take months to resolve.

**Codes**

&NA;

## ICD10

B36.0 Pityriasis versicolor

# Clinical Pearls

### &NA;

- Noncontagious macules of varying colors, with fine scale
- Recurrence in summer months
- More apparent after tanning. Skin areas with fungal infection do not tan; thus, hypopigmented areas become more visible.
- Warn patients that whiteness will remain for several months after treatment.

# Tinnitus

Donna I. Meltzer, MD

## BASICS

### DESCRIPTION

- Tinnitus is a perceived sensation of sound in the absence of an external acoustic stimulus; often described as a ringing, hissing, buzzing, or whooshing
- Derived from the Latin word *tinnire*, meaning Òto ringÓ (1)
- May be heard in one or both ears or centrally within the head (2)
- Two types: subjective (most common) and objective tinnitus
- Subjective tinnitus: perceived only by the patient; can be continuous, intermittent, or pulsatile
- Objective tinnitus: audible to the examiner; usually pulsatile; <1% cases (3)

### EPIDEMIOLOGY

#### Prevalence

- Tinnitus reported by 35 to 50 million adults in United States; although underreported, 12 million seek medical care (4).
- Affects 10-15% of adults
- Prevalence increases with age and peaks between ages of 60 and 69 years (5).
- Prevalence of 13-53% in general pediatric population (6)
- Ethnic: whites > blacks and Hispanics (4)
- Gender: males > females

#### Incidence

- Incidence increasing in association with excessive noise exposure
- Higher rates of tinnitus in smokers and hypertensives (5)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Precise pathophysiology is unknown; numerous theories have been proposed. Cochlear damage from ototoxic agents or noise exposure damage hair cells so that the central auditory system compensates, resulting in hyperactivity in cochlear nucleus and auditory cortex. Animal models have identified brain abnormalities resulting in increased firing and synchrony in auditory cortex (7).
- Causes of subjective tinnitus are the following:
  - Otologic: hearing loss, cholesteatoma, cerumen impaction, otosclerosis, Ménière disease, vestibular schwannoma
  - Ototoxic medications: anti-inflammatory agents (aspirin, NSAIDs); antimalarial agents (quinine, chloroquine); antimicrobial drugs (aminoglycosides); antineoplastic agents, loop diuretics, miscellaneous drugs (antiarrhythmics, antiulcer, anticonvulsants, antihypertensives, psychotropic drugs; anesthetics (3,5)
  - Somatic: temporomandibular joint (TMJ) dysfunction, head or neck injury
  - Neurologic: multiple sclerosis, spontaneous intracranial hypertension, vestibular migraine, type I Chiari malformation
  - Infectious: viral, bacterial, fungal
- Causes of objective tinnitus: patulous eustachian tube
  - Vascular: aortic or carotid stenosis, venous hum, arteriovenous fistula or malformation, vascular tumors, high cardiac output state (anemia)
  - Neurologic: palatal myoclonus, idiopathic stapedial muscle spasm

## *Genetics*

Minimal genetic component

## **RISK FACTORS**

- Hearing loss (but can have tinnitus with normal hearing)
- High level noise exposure
- Advanced age
- Use of ototoxic medications
- Otologic disease (otosclerosis, Ménière disease, cerumen impaction)

## **GENERAL PREVENTION**

- Avoid loud noise exposure and wear appropriate ear protection to prevent hearing loss.

- Monitor ototoxic medications and avoid prescribing more than one ototoxic agent concurrently.

## COMMONLY ASSOCIATED CONDITIONS

- Sensorineural hearing loss caused by presbycusis (age associated hearing loss) or prolonged loud noise exposure
- Conductive hearing loss due to cerumen, otosclerosis, cholesteatoma
- Psychological disorders: depression, anxiety, insomnia, suicidal ideation
- Despair, frustration, interference with concentration and social interactions, work hindrance

## DIAGNOSIS

### HISTORY

- Onset gradual (presbycusis) or abrupt (following loud noise exposure)
- Timing: can be continuous (hearing loss) or intermittent (Ménière disease)
- Pattern: nonpulsatile > pulsatile (often vascular cause)
- Location: bilateral > unilateral (vestibular schwannoma, cerumen, Ménière disease)
- Pitch: high pitch (with sensorineural hearing loss) > low pitch (Ménière disease)
- Associated symptoms: hearing loss, headache, noise intolerance, vertigo, TMJ dysfunction, neck pain
- Exacerbating factors: loud noise; jaw, head, or neck movements
- Alleviating factors: hearing aid, position change, medications
- Medication use (prescription, OTC, supplements)
- Hearing and past noise exposure (occupational, military, recreational)
- Psychosocial history (depression, sleep habits)
- Impact of tinnitus: Tinnitus Handicap Inventory, Tinnitus Functional Index

### PHYSICAL EXAM

- HEENT, neck, neurologic, and vascular examinations
- Ear: cerumen impaction, effusion, cholesteatoma
- Check hearing; air and bone conduction testing with 512- or 1,024-Hz tuning fork (Weber and Rinne tests)

- Eye: funduscopic exam for papilledema (intracranial hypertension) or visual field change (mass)
- TMJ: Palpate for tenderness and crepitus with movement.
- Cranial nerve, Romberg test (equilibrium), finger to nose, gait
- Auscultate for bruits or murmurs over ear canal, periauricular areas, orbit, neck, chest

## ***DIFFERENTIAL DIAGNOSIS***

Pulsatile tinnitus: carotid stenosis, aortic valve disease, AV malformation, high cardiac output state (anemia, hyperthyroidism), paraganglioma (glomus tumor) Nonpulsatile tinnitus: auditory hallucinations (8)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Tinnitus is a symptom; no objective test to confirm diagnosis
- Pure tone audiometry (air and bone conduction)
- Speech discrimination testing
- Tympanometry
- Auditory brainstem response (ABR); less sensitive and specific than MRI for diagnosis of vestibular schwannoma (3)
- Carotid Doppler ultrasonography (neck bruit)

## ***Initial Tests (lab, imaging)***

Little evidence to support lab testing other than targeted lab studies based on history and physical exam. Lab investigation is not indicated in all patients; use clinical judgment. Consider the following:

- CBC
- BUN/creatinine, fasting glucose, lipid panel
- Thyroid-stimulating hormone
- Clinical evaluation should precede radiologic studies.
- Nonpulsatile tinnitus: MRI with or without contrast
- Pulsatile tinnitus: Contrast-enhanced temporal bone CT, MRI, MRA/MRV, CTA/CTV, carotid ultrasound, and conventional angiography all have been used to work up pulsatile tinnitus.
- CTA/CTV; CTA evaluates middle ear and arterial causes (carotid artery stenosis, aberrant ICA, persistent stapedia artery); CTV evaluates venous causes (sinus thrombosis, sinus stenosis,

dehiscent jugular bulb) (9)[C].

- No studies have compared sensitivity and specificity of MRA/V with CTA/V in the evaluation of pulsatile tinnitus.
- Cerebral angiography is gold standard for diagnosis of suspected dural arteriovenous fistula.

### *Follow-Up Tests & Special Considerations*

Consider HIV, RPR, autoimmune panel, Lyme test, vitamin B<sub>12</sub> level.

### *Diagnostic Procedures/Other*

Electronystagmography (vestibular testing for MŽnière disease)

## **TREATMENT**

### *GENERAL MEASURES*

- Individualize treatment based on the severity of tinnitus and impact on function
- Reassure patient.
- Manage treatable pathology.
- Education, relaxation therapy, cognitive-behavioral therapy (CBT)
- Hearing aids (corrects hearing and might mask tinnitus); can be tried even if there is minimal hearing loss; no evidence to support or refute the use of hearing aids (10)[B]
- Protect hearing against future loud noise.
- Masking sound devices or generators on discontinuation might have decreased tinnitus (residual inhibition).
- Discontinue ototoxic medications.

---

P.1045

### *MEDICATION*

No pharmacologic agent has been shown to cure or consistently alleviate tinnitus.

#### *First Line*

- Antidepressants (SSRIs or TCAs): probably help with psychological distress. Newer review states insufficient evidence that antidepressant drug therapy improves tinnitus (11)[B].
- Melatonin decreases tinnitus intensity and improves sleep quality; most effective in men, those

without depression or prior treatment, and those with more severe bilateral tinnitus (12)[B].

## *Second Line*

- Anticonvulsants are used to treat tinnitus for years. Recent studies indicate that they may have a small effect (of doubtful clinical significance) on tinnitus (13)[A].
- Benzodiazepines help reduce tinnitus distress, but regular use discouraged.
- No difference between gabapentin and control group in patients with isolated tinnitus (14)[B].
- Higher caffeine intake associated with lower incidence of tinnitus in women (15)[B]

## *ISSUES FOR REFERRAL*

- Audiologist for comprehensive hearing evaluation and management
- Otolaryngologist, neurologist, or neurosurgeon depending on pathology
- Dental referral for TMJ treatment and dental orthotics (splint, night guard)
- Therapists for cognitive-behavioral therapy (CBT), biofeedback, education, and relaxation techniques

## *ADDITIONAL THERAPIES*

- Sound therapy (masking): Patients wear low-level noise generators to mask the tinnitus noise; commonly used, but no strong evidence for its efficacy (16)[B].
- CBT employs relaxation exercises, coping strategies, and deconditioning techniques to reduce arousal levels and reverse negative thoughts about tinnitus. Depression and severity of tinnitus improved with CBT (17)[A].
- Tinnitus retraining therapy (TRT) combines counseling, education, and acoustic therapy (soft music, sound machine) to minimize bothersome nature of tinnitus; often requires a team approach and up to
- Transcranial magnetic stimulation (TMS): A noninvasive method to stimulate neurons in the brain by rapidly changing magnetic fields; insufficient data to support long-term safety of repetitive TMS (19)[B]
- Neurofeedback: a method to help patients regulate abnormal oscillatory brain activity and reduce intensity of tinnitus
- Hyperbaric oxygen therapy: no beneficial effect on tinnitus (20)[A]

## *SURGERY/OTHER PROCEDURES*

- Cochlear implants (for severe sensorineural hearing loss)

- Ablation of cochlear nerve (destroys hearing)
- Epidural stimulation of secondary auditory cortex with implanted electrodes suppressed tinnitus in small subset of patients.
- Otosclerosis: stapedectomy surgery with implantation of ossicular prosthesis
- Severe Ménière disease not alleviated by medications: installation of endolymphatic shunt, labyrinthectomy, or vestibular neurectomy 2 years of therapy; might be more effective than sound masking (18)[B].
- Auditory neoplasms: surgical resection/radiation
- Pulsatile tinnitus due to atherosclerotic carotid artery disease: carotid endarterectomy

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Zinc supplements might improve tinnitus in those with zinc deficiency. One study in elderly did not demonstrate effectiveness of zinc treatment (21)[B].
- Ginkgo biloba has potential benefit but recent reviews question the effectiveness (22)[B].
- One evidence-based practice guideline does not recommend Ginkgo biloba, melatonin, zinc, or other dietary supplements for treatment of persistent, bothersome tinnitus (23)[C].
- Botulinum toxin (for palatal myoclonus)
- Acamprosate (used to treat alcohol dependence): Small studies noted improvement in tinnitus severity.
- Hypnosis (unknown effectiveness)
- Acupuncture (unknown effectiveness)

## *INPATIENT CONSIDERATIONS*

### **Admission Criteria/Initial Stabilization**

Not applicable

### **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Audiologist: for hearing evaluation and therapy
- Counseling as needed for psychological distress

- Family physician: as needed for support and guidance

## **PATIENT EDUCATION**

- Help patients understand the relatively benign nature of tinnitus.
- Self-help groups
- American Tinnitus Association: (800) 634-8978; <http://www.ata.org/>
- National Institute on Deafness and Other Communication Disorders: (800) 241-1044; <http://www.nidcd.nih.gov/Pages/default.aspx>
- American Academy of Family Physicians: <http://familydoctor.org>

## **PROGNOSIS**

- Tinnitus persisted in 80% of older patients and increased in severity in 50% (3).
- Focus on managing tinnitus and reducing severity, not curing.

## Codes

**&NA;**

### ICD10

- H93.19 Tinnitus, unspecified ear
- H93.11 Tinnitus, right ear
- H93.12 Tinnitus, left ear

## Clinical Pearls

**&NA;**

- People have different levels of tolerance to tinnitus. It may affect sleep, concentration, and emotional state. Many patients with chronic tinnitus have depression.
- To keep tinnitus from worsening, avoid loud noises and minimize stress.
- Optimal management may involve multiple strategies.

# Tobacco Use and Smoking Cessation

Felix B. Chang, MD, DABMA, FAAMA

## BASICS

### DESCRIPTION

- Use of tobacco of any form
- *Smokeless tobacco* refers to tobacco products that are sniffed, sucked, or chewed.
- Nicotine sources: cigars, pipes, waterpipes, hookahs, and cigarettes

### EPIDEMIOLOGY

#### Incidence

- 2.4 million new smokers annually in the United States (2.6% initiation rate)
- 58.8% of new smokers are <18 years of age (5.8% initiation rate for teens).

#### Prevalence

- 443,000 deaths annually in the United States
- Cigarette smoking among adults in the United States: 21.3% of adults in 2012 to 2013
- Highest among those aged 18 to 25 (40.8%)
- Adults aged >25 years (28.5%)
- Race: highest among whites (22.1%) and African Americans (21.3%) and is lower among Hispanics (14.6%) and Asians (12%)
- Gender: male > female (21.5% vs. 17.3%)
- Inversely proportional to education level
- 31% in men >15 years old from 187 countries in 2012

### ETIOLOGY AND PATHOPHYSIOLOGY

- Addiction due to nicotine's rapid stimulation of the brain's dopamine system (teenage brain especially susceptible)

- Atherosclerotic risk due to adrenergic stimulation, endothelial damage, carbon monoxide, and adverse effects on lipids
- Direct airway damage from cigarette tar
- Carcinogens in all tobacco products

## *RISK FACTORS*

- Presence of a smoker in the household
- Easy access to cigarettes
- Perceived parental approval of smoking
- Comorbid stress and psychiatric disorders
- Low self-esteem/self-worth
- Poor academic performance
- Boys: high levels of aggression and rebelliousness
- Girls: preoccupation with weight and body image

## *GENERAL PREVENTION*

- Most first-time tobacco use occurs before high school graduation, so educational interventions should target students in grade and middle schools and must address health consequences and psychosocial aspects of smoking.
- The AAFP's Tar Wars program has targeted 4th and 5th graders successfully.
- Other helpful measures include the following:
  - Smoking bans in public areas and workplaces
  - Restriction of minors' access to tobacco
  - Restrictions on tobacco advertisements
  - Raising prices through taxation
  - Media literacy education
  - Tobacco-free sports initiatives

## *COMMONLY ASSOCIATED CONDITIONS*

- Coronary artery disease
- Cerebrovascular disease

- Peripheral vascular disease
- Abdominal aortic aneurysm (AAA)
- COPD
- Cancer of the lip, oral cavity, pharynx, larynx, lung, esophagus, stomach, pancreas, kidney, bladder, cervix, and blood
- Pneumonia
- Osteoporosis
- Periodontitis
- Alcohol use
- Depression and anxiety
- Reduced fertility

### *Pregnancy Considerations*

Women who smoke or are exposed to 2nd-hand smoke during pregnancy have increased risks of miscarriage, placenta previa, placental abruption, premature rupture of membranes, preterm delivery, low-birth-weight infants, and stillbirth.

### *Pediatric Considerations*

- 2nd-hand smoke increases the risk of the following in infants and children:
  - Sudden infant death syndrome
  - Acute upper and lower respiratory tract infections
  - More frequent and more severe exacerbations of asthma
  - Otitis media and need for tympanostomies
- Nicotine passes through breast milk, and its effects on the growth and development of nursing infants are unknown.

## **DIAGNOSIS**

### **HISTORY**

- Ask about tobacco use and 2nd-hand smoke exposure at every physician encounter.
- Type and quantity of tobacco used

- Pack years = packs/day × years
- Awareness of health risks
- Assess interest in quitting.
- Identify triggers for smoking.
- Prior attempts to quit: method, duration of success, reason for relapse

## PHYSICAL EXAM

- General: tobacco smoke odor
- Skin: premature face wrinkling
- Mouth: nicotine-stained teeth; inspect for suspicious mucosal lesions
- Lungs: crackles, wheezing, increased or decreased volume
- Vessels: carotid or abdominal bruits, abdominal aortic enlargement, peripheral pulses, stigmata of peripheral vascular disease

## DIAGNOSTIC TESTS & INTERPRETATION

- CXR for patients with pulmonary symptoms or signs of cancer but not for screening
- The USPSTF recommends one-time screening US for AAA in men <sup>3</sup>65 years of age who ever smoked (number needed to screen to prevent 1 AAA = 500).

## Diagnostic Procedures/Other

PFTs for smokers with chronic pulmonary symptoms, such as wheezing and dyspnea

## TREATMENT

Both behavioral counseling and pharmacotherapy benefit patients who are trying to quit smoking especially when use in combination.

### ALERT

Provider recommending smoking cessation at *every clinical visit* improves cessation rates. Nonpharmacologic approaches are appropriate for pregnant women and patients who smoke < 10 cigarettes/day.

## GENERAL MEASURES

- Behavioral counseling includes the 5 As of promoting smoking cessation:

Ask about tobacco use at every office visit.

- Advise all smokers to quit.
  - Assess the patient's willingness to quit.
  - Assist the patient in his or her attempt to quit.
  - Arrange follow-up.
- Patients ready to quit smoking should set a quit date within the next 2 weeks. No difference in success rates between patients who taper prior to their quit date and those who stop abruptly.
  - Success increased with a quitting partner, such as a spouse, friend, or coworker, to provide mutual encouragement.
  - Patients desiring to quit should dispose of all smoking paraphernalia (such as lighters) on their quit dates to make relapse more difficult.
  - Patients must anticipate and avoid social/environmental triggers for smoking and should have a plan for dealing with the urge to smoke.

## *MEDICATION*

### **First Line**

- Varenicline (Chantix): 0.5 mg/day PO for 3 days, then 0.5 mg BID for 4 days, then 1 mg BID for 11 weeks (1)[A]:
  - Start 1 to 4 weeks prior to smoking cessation and continue for 12 to 24 weeks.
  - Superior to placebo and to bupropion; number needed to treat = 7
  - May be combined with nicotine replacement therapy
  - S/E: nausea, insomnia, headache, depression, suicidal ideation; safety not established in adolescents or patients with psychiatric or cardiovascular disease; pregnancy Category C
- Bupropion SR (Zyban): 150 mg PO for 3 days, then 150 mg BID:
  - Start 1 week prior to smoking cessation, and continue for 7 to 12 weeks.
  - Twice as effective as placebo
  - Drug of choice for patients with depression or schizophrenia
  - May be combined with varenicline and NRT in men who smoke >1 PPD
- S/E: tachycardia, headache, nausea, insomnia, dry mouth; contraindicated in patients who have seizure disorders or anorexia/bulimia; pregnancy Category C(1),(2)[A]

Nicotine replacement therapy (NRT) (e.g., patch, gum, lozenge, inhaler, nasal spray) (1),(2)  
[A]:

- Improves quit rates by 50-70% versus placebo
- Over-the-counter

P.1047

- Patch (NicoDerm CQ 21, 14, and 7 mg):
  - 1 patch q24h
  - Start with 21 mg if smoking <sup>3</sup>10 cigarettes/day; otherwise, start with 14 mg.
  - 6 weeks on initial dose, then taper
  - 2 weeks each on subsequent doses
  - No proven benefit beyond 8 weeks
- E-cigarettes
  - Contain less nicotine than cigarette Considered less ÖdangerousÓ than tobacco but not as well studied as other NRT (3)[B]
  - Conflicting data on whether teen use increases or decreases risk to cigarette progression
- Gum (Nicorette, 2 and 4 mg):
  - Use 4 mg if smoking >25 cigarettes/day
  - Chew 1 piece q1-2h for 6 weeks, then 1 piece q2-4h for 3 weeks, then 1 piece q4-8h for 3 weeks.
- May use in combination with bupropion; monitor for hypertension
- S/E: headache, pharyngitis, cough, rhinitis, dyspepsia; all mainly with inhaler and spray forms
- Pregnancy Category D

## Second Line

- Nortriptyline: 25 to 75 mg/day PO or in divided doses:
  - Start 10 to 14 days prior to smoking cessation and continue for at least 12 weeks.
  - Efficacy similar to bupropion, but side effects more common; pregnancy Category D
  - The antidepressants bupropion and nortriptyline aid long-term smoking cessation (4)[A].
- Clonidine: 0.1 mg PO BID or 0.1 mg/day transdermal patch weekly (1):

- Side effects: hypotension, bradycardia, depression, fatigue; pregnancy Category C

## ***ADDITIONAL THERAPIES***

The following interventions have been shown to be effective in helping patients quit smoking:

- Advice from nurses, especially in hospital
- Individual counseling/group therapy
- Telephone counseling/web-based cessation programs
- Exercise (not conclusive, ineffective) (5)[A]
- Acupuncture: short-term effects (6)[A]
- Naltrexone. No evidence (7)[A]
- Opiates antagonist. No evidence (1)[A]

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Acupuncture, aversive therapy, and hypnosis have not been proven to enhance long-term smoking cessation.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Follow up 3 to 7 days after scheduled quit date and at least monthly for 3 months thereafter.
- Telephone follow-up if office visits not feasible
- Refraining from tobacco products for first 2 weeks is critical to long-term abstinence.
- Encourage patients who relapse to try again. Most smokers experience <sup>31</sup> failed attempts before quitting permanently. Reinforce behavioral interventions (8)[A].

### ***Patient Monitoring***

- Short-term withdrawal symptoms include dysphoria, depressed mood, irritability, anxiety, insomnia, increased appetite, and poor concentration.
- Longer term risks of smoking cessation include weight gain (4 to 5 kg on average) and depression.
- Quitting also is associated with exacerbations of ulcerative colitis and worsening of cognitive

function in patients with schizophrenia.

- Nicotine withdrawal syndrome: dysphoric or depressed mood, insomnia, irritability, frustration, or anger; anxiety, difficulty concentrating, restlessness, and increased appetite or weight gain
- Lung cancer risk by smoking status: heavy smokers 1.00, light smokers 9.44 (0.35 to 0.56), ex-smokers 0.17 (0.13 to 0.23), never smoker 0.09 (0.06 to 0.13); adjusted hazard ratio (95% CI) (9)

## DIET

Healthy eating for limiting weight gain following smoking cessation

## PATIENT EDUCATION

1-800-QUIT-NOW: free counseling, resources, and support for quitting

## PROGNOSIS

- Measurable cardiovascular benefits of smoking cessation begin as early as 24 hours after quitting and continue to mount until the risk is reduced to that of nonsmokers by 5 to 15 years.
- People who quit smoking after a heart attack or cardiac surgery reduce their risk of death by 1/3.
- Relapse rates initially >60% but decrease to 2-4% per year after completing 2 years of abstinence (8)[A].

## COMPLICATIONS

- Disability and premature death due to heart attack, stroke, cancer, COPD
- Smoking more than doubles the risk of coronary artery disease and doubles the risk of stroke.
- Smokers are 12 to 22 times more likely than nonsmokers to die from lung cancer.

Nicotine Addiction; Substance Use Disorders

**&NA;**

### **ICD10**

- F17.210 Nicotine dependence, cigarettes, uncomplicated
- F17.213 Nicotine dependence, cigarettes, with withdrawal
- F17.211 Nicotine dependence, cigarettes, in remission

## **Clinical Pearls**

**&NA;**

- Every patient who uses tobacco should be offered smoking cessation.
- Use the 5 As: ask, advise, assess, assist, and arrange
- Behavioral counseling and medication are most effective for helping patients to quit smoking when they are used in combination.
- Depression with suicidal ideations is a contraindication to use varenicline.
- Even brief advice to quit has been shown to increase quit rates.
- Following relapse, smokers should be encouraged to make another attempt to stop smoking.

# Tourette Syndrome

Ravin V. Patel, MD

Dustin Creech, MD

## BASICS

### DESCRIPTION

- Tourette syndrome (TS) is a movement disorder most commonly seen in school-age children. A childhood-onset neurobehavioral disorder characterized by the presence of multiple motor and at least one phonic tic (see *Physical Exam*).
- Tics are sudden, brief, repetitive, stereotyped motor movements (motor tics) or sounds (phonic tics) produced by moving air through the nose, mouth, or throat.
- Tics tend to occur in bouts.
- Tics can be simple or complex.
  - Motor tics precede vocal tics.
  - Simple tics precede complex tics.
- Tics often are preceded by sensory symptoms, especially a compulsion to move.
- Patients are able to suppress their tics, but voluntary suppression is associated with an inner tension that results in more forceful tics when suppression ceases.
- System(s) affected: nervous

### EPIDEMIOLOGY

#### Incidence

- The onset occurs before 18 years of age.
- Predominant age
  - Average age of onset: 7 years (3 to 8 years)
  - Tic severity is greatest at ages 7 to 12 years.
    - 96% present by age 11 years

- Of children with TS, 50% will experience complete resolution of symptoms by age 18 years (based on self-reporting).
- Predominant sex: male <sup>3</sup> female (3:1)
- Predominant race/ethnicity: clinically heterogeneous disorder, but non-Hispanic whites (2:1) compared with Hispanics and/or blacks

## *Prevalence*

0.77% overall in children

- 1.06% in boys
- 0.25% in girls

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Abnormalities of dopamine neurotransmission and receptor hypersensitivity, most likely in the ventral striatum, play a primary role in the pathophysiology.

- Abnormality of basal ganglia development
- Thought to result from a complex interaction between social, environmental, and multiple genetic abnormalities.
- Mechanism is uncertain; may involve dysfunction of basal ganglia-thalamocortical circuits, likely involving decreased inhibitory output from the basal ganglia, which results in an imbalance of inhibition and excitation in the motor cortex
- Controversial pediatric autoimmune neuropsychiatric disorder association with *Streptococcus* (PANDAS)
  - TS/OCD cases linked to immunologic response to previous group A *β*-hemolytic streptococcal infection (GABHS)
  - Thought to be linked to 10% of all TS cases
  - Five criteria
    - Presence of tic disorder and/or OCD
    - Prepubertal onset of neuropsychosis
    - History of sudden onset of symptoms and/or episodic course with abrupt symptom exacerbation, interspersed with periods of partial/complete remission
    - Evidence of a temporal association between onset/exacerbation of symptoms and a prior streptococcal infection

- Adventitious movements during symptom exacerbation (e.g., motor hyperactivity)

## Genetics

- Predisposition: frequent familial history of tic disorders and OCD
- Precise pattern of transmission and genetic origin unknown. Recent studies suggest polygenic inheritance with evidence for a locus on chromosome 17q; sequence variants in *SLITRK1* gene on chromosome 13q also are associated with TS.
- Higher concordance in monozygotic compared with dizygotic twins; wide range of phenotypes

## RISK FACTORS

- Risk of TS among relatives: 9.8-15%
- First-degree relatives of individuals with TS have a 10- to 100-fold increased risk of developing TS.
- Low birth weight, maternal stress during pregnancy, severe nausea and vomiting in 1st trimester

## COMMONLY ASSOCIATED CONDITIONS

- OCD (28-67%)
- ADHD (50-60%)
- Conduct disorder
- Depression/anxiety including phobias, panic attacks, and stuttering
- Learning disabilities (23%)
- Impairments of visual perception, sleep disorders, restless leg syndrome, and migraine headaches

## DIAGNOSIS

### HISTORY

Diagnosis of TS is based on history and clinical presentation (i.e., observation of tics with/without presence of coexisting disorders). Identify comorbid conditions.

## PHYSICAL EXAM

Typically, the physical exam is normal.

- Motor and vocal tics are the clinical hallmarks.
- Tics fluctuate in type, frequency, and anatomic distribution over time.
- Multiple motor tics include facial grimacing, blinking, head/neck jerking, tongue protruding, sniffing, touching, and burping.
- Vocal tics include grunts, snorts, throat clearing, barking, yelling, hiccupping, sucking, and coughing.
- Tics are exacerbated by anticipation, emotional upset, anxiety, or fatigue.
- Tics subside when patient is concentrating/absorbed in activities.
- Motor and vocal tics may persist during all stages of sleep, especially light sleep.
- Blink-reflex abnormalities may be observed.
- No known clinical measures reliably predict children who will continue to express tics in adulthood; severity of tics in late childhood is associated with future tic severity.
- *Diagnostic and Statistical Manual of Mental Disorders* (5th ed.; *DSM-5*) criteria (1)[C]:
  - A. Both multiple motor and one or more vocal tics have been present at some time during the illness, although not necessarily concurrently.
  - B. The tics may wax and wane in frequency but have persisted for more than 1 year since first tic onset.
  - C. Onset is before age 18 years.
  - D. The disturbance is not attributable to the physiologic effects of a substance (e.g., cocaine) or another medical condition (e.g., Huntington disease, postviral encephalitis).

## ***DIFFERENTIAL DIAGNOSIS***

- Chorea/Huntington disease
- Myoclonus
- Seizure
- Ischemic or hemorrhagic stroke
- Essential tremor
- Posttraumatic/head injury
- Headache
- Dementia

- Wilson disease
- Sydenham chorea
- Multiple sclerosis
- Postviral encephalitis
- Toxin exposure (e.g., carbon monoxide, cocaine)
- Drug effects (e.g., dopamine agonists, fluoroquinolones)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### **Initial Tests (lab, imaging)**

- No definitive lab tests diagnose TS. Based on clinical features, particularly the presence of multiple motor and vocal tics.
- Thyroid-stimulating hormone (TSH) should be measured because of association of tics with hyperthyroidism.
- No imaging studies diagnose TS
- EEG shows nonspecific abnormalities; useful only to differentiate tics from epilepsy.

### *Test Interpretation*

- Smaller caudate volumes in patients with TS
- Striatal dopaminergic terminals are increased, as is striatal dopamine transporter (DAT) density.

## **TREATMENT**

### *GENERAL MEASURES*

- Treatment assessment
  - Yale Global Tic Severity Score
  - Tourette-Syndrome Severity Scale
  - Global Assessment of Functioning Scale
  - Gilles de la Tourette Syndrome-Quality of Life Scale
- A detailed history is crucial to management, because tics and comorbidities are interrelated.

Goal of treatment should be to improve social functioning, self-esteem, and quality of life.

- Educate that tics are neither voluntary nor psychiatric.
- Many patients require no treatment; patient should play an active role in treatment decisions.
- Educate patient, family, teachers, and friends to identify and address psychosocial stressors and environmental triggers.
- No cure for tics: Treatment is purely symptomatic, and multimodal treatment usually is indicated.
- Neurologic and psychiatric evaluation may be useful for other primary disorders and comorbid conditions (especially ADHD, OCD, and depression).
- TS clusters with several comorbid conditions; each disorder must be evaluated for associated functional impairment because patients often are more disabled by their psychiatric conditions than by the tics; choice of initial treatment depends largely on worst symptoms (tics, obsessions, or impulsivity).

---

P.1049

- Nonpharmacologic therapy—reassurance and environmental modification, identification and treatment of trigger, and cognitive behavior therapy
- When pharmacotherapy is employed, monotherapy is preferred to polytherapy.

## MEDICATION

### First Line

- Atypical antipsychotics
  - Risperidone: now recommended for standard therapy (2) [A]
    - Initiate 0.25 BID; titrate to 0.25 to 6 mg/day
    - As effective as haloperidol and pimozide for tics with fewer side effects
    - Effective against comorbidities such as OCD
    - Side effects may limit use: sedation, weight gain, and fatigue.
- $\alpha_2$ -Adrenergic receptor agonists (2)[B]
  - Historically first-line agents due to favorable side effect profile, but suboptimal efficacy in limited clinical trials
  - Side effects: sedation and hypotension common
    - Initiate therapy gradually and taper when discontinuing to avoid cardiac adverse events.

- Clonidine 0.1 to 0.3 mg/day given BID-TID
  - Maximum dose: 0.5 mg/day
  - 25-50% of patients report at least some reduction in tics.
- Guanfacine 1 to 3 mg/day given daily or BID
  - Less sedating and longer duration of action compared with clonidine
  - Improves motor/vocal tics by 30% in some studies; no better than placebo in others

## *Second Line*

- Neuroleptics
  - Typical antipsychotics
    - High risk for extrapyramidal symptoms (EPS)
    - Haloperidol: initiate 0.5 mg/day and titrate 0.5 mg/week up to 1 to 4 mg at bedtime (3) [B]
      - FDA-approved for treating tics
      - Considered last option of typical antipsychotics due to lower efficacy and increased side effects compared to similar medications
    - Pimozide: initiate 0.5 mg/day and titrate 0.5 mg/week up to 1 to 4 mg at bedtime (4)[A]
      - FDA-approved for treating tics
      - Risk of cardiac toxicity (prolonged Q-T interval and arrhythmias); must be given under ECG monitoring; long-term use may induce sedation, weight gain, depression, pseudoparkinsonism, and akathisia.
      - Found to work better in long-term control of tics versus acute exacerbations
    - Fluphenazine: 2.5 to 10 mg/day
      - Effective but less favored due to side effects
  - Atypical antipsychotics (3)[C]
    - Olanzapine: initiate 2.5 to 5.0 mg/day; titrate up to 20 mg/day
      - Equally effective as haloperidol and pimozide
      - May cause metabolic disturbances and weight gain

- Quetiapine: initiate 100 to 150 mg/day; titrate to 100 to 600 mg/day
  - Well tolerated but limited data exists
- Ziprasidone: 5 to 40 mg/day
- Aripiprazole: initiate 2 mg/day; titrate up to 20 or 30 mg/day
  - Few studies but favorable side-effect profile
- Alternative treatments
  - Topiramate: 25 to 200 mg/day (2)[A]; promising data but not sufficient efficacy so far to recommend as first or second line
  - Tetrabenazine
  - Baclofen
- Treatment of ADHD in patients with tics (5)[A]
  - Stimulants
    - Comorbid tic disorder is not a serious contraindication, as previously held; exacerbation of tics is neither clinically significant nor common.
    - Methylphenidate: 2.5 to 30 mg/day
    - Dextroamphetamine: 5 to 30 mg/day
  - $\alpha_2$ -Adrenergic agonists
    - Guanfacine
    - Clonidine
      - The combination of methylphenidate and clonidine has shown superior efficacy in treating both ADHD and tic symptoms compared to monotherapy with either agent in one trial.
  - Other medications
    - Atomoxetine
    - Desipramine
- Treatment of OCD in patients with tics (6)[B]
  - SSRIs
    - First-line treatment of OCD; can be used in TS as well

- Side effects include nausea, insomnia, sexual dysfunction, headache, and agitation.
- Comorbid tic disorder not a contraindication; exacerbation of tics neither clinically significant nor common.
- Black box warning for suicidality with SSRIs
- Fluoxetine: 10 to 80 mg/day
- Fluvoxamine: 50 to 300 mg/day
- Sertraline: 50 to 200 mg/day
- Tricyclic antidepressants
  - Clomipramine: 25 to 200 mg/day
    - Can be used in patients refractory to SSRIs or to augment SSRIs in partial responders
    - Side effects: weight gain, dry mouth, lowered seizure threshold, and constipation; ECG changes, including Q-T prolongation and tachycardia

## ***ADDITIONAL THERAPIES***

- Botulinum toxin injections in severe cases or where chronic medication therapy is not preferred.
- Habit-reversal training provides a viable tic suppression treatment: Works equally for motor and vocal tics.

## ***SURGERY/OTHER PROCEDURES***

Thalamic ablation and deep brain stimulation have been used experimentally (7)[C].

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Nonpharmacologic therapy

- Reassurance and environmental modification
- Identification and treatment of triggers
- Behavioral therapy: awareness/assertiveness training, relaxation therapy, habit-reversal therapy, and self-monitoring has shown to significantly decrease tic severity.
- Hypnotherapy
- Biofeedback
- Acupuncture

- Cannabinoids: insufficient evidence to recommend; small trials show small positive effects in some parameters (8)[A].

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### **Patient Monitoring**

Observe for associated psychiatric disorders.

### *PATIENT EDUCATION*

- Reassurance that many patients with tics do not need medication; often education and/or therapy is all that is required.
- National Tourette Syndrome Association: <http://www.tsa-usa.org>

### *PROGNOSIS*

- Symptoms will fluctuate throughout illness.
- Tic severity typically stabilizes by age 25 years.
- 60-75% of young adults show some improvement in symptoms.
- 10-40% of patients will exhibit full remission.

Curtis A, Clarke CE, Rickards HE. Cannabinoids for Tourette's syndrome. *Cochrane Database Syst Rev.* 2009;(4):CD006565.

## Codes

**&NA;**

### ICD10

F95.2 Tourette's disorder

## Clinical Pearls

**&NA;**

- TS is diagnosed by history and witnessing tics; have parent video patient's tics if not present on exam in your office.
- Nearly 50% of children with tics also have ADHD. Stimulants may be used as first-line treatment for ADHD (tics are not a contraindication, as previously believed).

# Toxoplasmosis

Jonathan MacClements, MD, FAAFP

## BASICS

- *Toxoplasma gondii* is an obligate intracellular protozoan parasite.
- Most common latent protozoan infection
- Clinically significant disease typically manifests only in pregnancy or in an immunocompromised patient.

## DESCRIPTION

- Acute self-limited infection in immunocompetent
- Acute symptomatic or reactivated latent infection in immunocompromised persons
- Congenital toxoplasmosis (acute primary infection during pregnancy)
- Ocular toxoplasmosis

## Pediatric Considerations

- The earlier fetal infection occurs, the more severe.
- Risk of perinatal death is 5% if infected in 1st trimester.

## Pregnancy Considerations

- Pregnant immunocompromised and HIV-infected women should undergo serologic testing.
- Seronegative pregnant women should receive preventive counseling.
- Serologic testing during pregnancy remains controversial.

## EPIDEMIOLOGY

### Incidence

- Prevalence of congenital toxoplasmosis in the United States: 10 to 100/100,000 live births
- Predominant sex: male > female

## Prevalence

- Present in every country. Seropositivity rates range from <10% to >90% (1)[A].
- In the United States, 11% of individuals aged 6 to 49 years are seropositive. Age-adjusted prevalence in the United States is 22.5%.
- Seroprevalence among women in the United States is 15%.

## ETIOLOGY AND PATHOPHYSIOLOGY

### Transmission to humans

- Ingestion of raw or undercooked meat, food, or water containing tissue cysts or oocysts; usually from soil contaminated with feline feces
- Transplacental passage from infected mother to fetus; risk of transmission is 30% on average.
- Blood product transfusion and solid-organ transplantation
- Ingested *T. gondii* oocysts enter host's gastrointestinal tract where bradyzoites/tachyzoites are released, penetrate contiguous cells, replicate and are transported to susceptible tissues where clinical disease manifests.

## Genetics

Human leukocyte antigen (HLA) DQ3 is a genetic marker of susceptibility in AIDS.

## RISK FACTORS

- Immunocompromised states, including HIV infection with CD4 cell count <100/ $\mu$ g/L
- Primary infection during pregnancy; risk of fetal transmission increases with gestational age at seroconversion. Transmission in the 1st trimester is associated with more severe consequences.
- Chronically infected pregnant women who are immunocompromised have an increased risk of transmitting congenital toxoplasmosis.

## GENERAL PREVENTION

Prevention is important in seronegative pregnant women and immunodeficient patients.

- Avoid eating undercooked meat: Cook to 152°F (66°C) or freeze for 24 hours at  $-20^{\circ}\text{C}$  -  $-12^{\circ}\text{C}$ .
- Avoid drinking unfiltered water.
- Wash produce thoroughly.
- Strict hand hygiene after touching soil

- Wear gloves and wash hands after handling raw meat or cat litter.
- Avoid shellfish (*Toxoplasma* cysts).

## COMMONLY ASSOCIATED CONDITIONS

- Chorioretinitis; self-limiting, febrile lymphadenopathy; mononucleosis-like illness
- An unclear association exists between schizophrenia and several infectious agents including *T. gondii*.

## DIAGNOSIS

### HISTORY

- Congenital toxoplasmosis
  - Clinical presentation varies widely; 80% of patients are asymptomatic at birth.
  - Classic triad (*uncommon*) : chorioretinitis, hydrocephalus, cerebral calcifications
  - Manifestations may include prematurity, intrauterine growth retardation (IUGR).
  - Jaundice, rash accompanying a mononucleosislike illness
  - Mental retardation, seizures, visual defects, spasticity, sensorineural hearing loss
- Ocular toxoplasmosis
  - Chorioretinitis: focal necrotizing retinitis
  - Yellowish-white elevated cotton patch
  - Congenital disease usually bilateral; acquired is more often unilateral.
  - Symptoms include blurred vision, scotoma, pain, and photophobia.
- Acute toxoplasmosis (immunocompetent host)
  - ~ 90% of patients are asymptomatic.
  - Most common manifestation is bilateral, symmetric, nontender cervical lymphadenopathy.
  - Constitutional symptoms such as fever, chills, and sweats are usually mild.
  - Headaches, myalgias, pharyngitis, hepatosplenomegaly, and diffuse nonpruritic maculopapular rash may occur.
  - Pregnant women are often asymptomatic.

- Most common site is CNS with toxoplasmic encephalitis.
- Headache; focal neurologic deficits and seizures
- Fever usually present
- Extracerebral toxoplasmosis: pneumonitis; chorioretinitis; rarely: GI system, liver, musculoskeletal system, heart, bone marrow, bladder, and orchitis

## *PHYSICAL EXAM*

- In adults: fever, lymphadenopathy, nonpruritic rash
- In newborns: hydrocephalus, neurologic abnormalities, hepatosplenomegaly, chorioretinitis, microcephaly, mental retardation

## *DIFFERENTIAL DIAGNOSIS*

Syphilis, lymphoma, progressive multifocal leukoencephalopathy, cryptococcal meningitis, congenital TORCH infections, *Listeria* infection, tuberculosis (TB), erythroblastosis fetalis

## *DIAGNOSTIC TESTS & INTERPRETATION*

- CBC: atypical lymphocytosis, anemia, thrombocytopenia
- Serology interpretation
  - In acute infection, IgM antibodies appear within the 1st week.
  - Diagnosis can be made if initial test demonstrates positive IgM and negative IgG, with both tests being positive 2 weeks later.
  - If follow-up IgG remains negative 2 to 4 weeks later but IgM is still positive, it is likely a false positive.
  - Negative IgG rules out prior infection (IgG remains detectable for life).
- Types of serologic tests
  - ELISA: most commonly used
  - Sabin-Feldman dye test: Gold standard against which all other serologic assays are compared.
  - IFA test: more available in commercial labs
  - ISAGA: widely available commercially; more sensitive and specific than IFA for detecting IgM

Avidity testing: confirmatory test to establish whether positive IgM/IgG reflects recent or chronic infection

- PCR: *T. gondii* DNA amplification in blood or amniotic fluid; used for diagnosis of fetal infection
- Culture (rarely necessary): Organism can be isolated either by cell culture or by mouse inoculation.

### *Initial Tests (lab, imaging)*

- Diagnosis of primary infection is typically based on history and confirmed by serology.
- Serum *Toxoplasma* -specific IgG and IgM are first step.
- According to the result of IgM test, determine IgG avidity.
- Diagnosis of maternal infection and congenital toxoplasmosis
  - Pregnant women who have mononucleosis-like illness but negative heterophile test should be tested for toxoplasmosis.
  - Maternal infection accurately diagnosed when based on two blood samples at least 2 weeks apart showing seroconversion
  - High avidity of IgG during 1st trimester argues against maternal primary infection.
  - Real-time PCR analysis for *T. gondii* in amniotic fluid predicts fetal infection and helps guide appropriate treatment and surveillance.
  - Fetal ultrasound is useful for prognosis.
  - Routine screening for toxoplasmosis is not recommended.
- Diagnosis of congenital toxoplasmosis after birth
  - Serology requires several serum samples for IgM and IgA antibodies.
  - Sampling of the cord or peripheral blood should be done within the first 2 weeks.
  - Ophthalmologic, auditory, and neurologic examinations; lumbar puncture; and head CT should be performed.
- Diagnosis of toxoplasmic encephalitis
  - Serology for IgG
  - Imaging: MRI is more sensitive than CT scan for identification of characteristic ring-enhancing brain lesions.

- MRI: for identifying multiple ring-enhancing brain lesion in AIDS patients with cerebral

toxoplasmosis

- SPECT and PET scans: can help distinguish toxoplasmosis from CNS lymphoma

## *Diagnostic Procedures/Other*

- Lymph node biopsy
- Brain biopsy in CNS disease
- Amniocentesis with PCR (risk of false negatives and false positives)
- Placental isolation of *Toxoplasma* is diagnostic.

## *Test Interpretation*

- Confirmatory, meningocerebritis ± abscesses with necrosis, Giemsa
- Lymph node histology shows triad of:
  - Reactive follicular hyperplasia
  - Irregular clusters of epithelioid histiocytes on and blurring margins of germinal centers
  - Distension of sinuses with monocytoïd cells
- Sensitivity of triad 62.5%, specificity 91.3%

## **TREATMENT**

### **GENERAL MEASURES**

Immunocompetent patients usually require no treatment.

### **MEDICATION**

#### **First Line**

##### **ALERT**

*Important:* All pyrimethamine-containing regimens should include leucovorin (folinic acid 10 to 25 mg/day PO) during and 1 week after completion of pyrimethamine to prevent drug-induced hematologic toxicity (2)[A].

- Treatment in immunocompromised hosts
  - Initial regimen of choice is pyrimethamine 200 mg loading dose PO, followed by 50 mg/day plus sulfadiazine 4 to 6 g/day PO in 4 divided doses; for those intolerant or allergic to

sulfadiazine, clindamycin 600 to 1,200 mg IV or 450 mg PO QID can be used instead.

- Alternative regimens for patients intolerant to sulfadiazine and clindamycin include the following:
  - Pyrimethamine: 200 mg loading dose PO, followed by 50 mg/day plus azithromycin 900 to 1,200 mg PO once daily
  - Pyrimethamine: 200 mg loading dose PO, then 50 mg/day plus atovaquone 1,500 mg PO BID
  - Sulfadiazine: 1,000 to 1,500 mg QID plus atovaquone 1,500 mg BID
  - Trimethoprim-sulfamethoxazole: 10/50 mg/kg/day PO or IV divided BID (for 30 days) may be a costeffective alternative.
- Duration of therapy: typically 6 weeks, lower doses for secondary prophylaxis (2)[A]
- Use adjunctive steroids should in patients with signs of increased intracranial pressure.
- Anticonvulsants, if there is a history of seizures
- Prophylaxis in immunocompromised patients
  - Primary prophylaxis: indicated for patients with HIV infection and CD4 count <100 cells/ $\mu$ m<sup>3</sup> who are *T. gondii* IgG-positive
    - Trimethoprim-sulfamethoxazole-DS: 1 tablet PO daily. Alternative for sulfa allergy is dapsone 50 mg/day PO *plus* pyrimethamine 50 mg PO weekly *plus* leucovorin 25 mg PO weekly *or* atovaquone 1,500 mg PO daily.
  - Secondary prophylaxis: Following 6 weeks of therapy, administer lower doses of drugs:
    - Sulfadiazine 2 to 4 g/day in two to four divided doses *plus* pyrimethamine 25 to 50 mg/day is the first choice.
    - Alternative regimens include clindamycin 600 mg PO q8h *plus* pyrimethamine 25 to 50 mg/day PO *or* atovaquone 750 mg PO BID to QID  $\pm$  pyrimethamine 25 mg PO daily.
- Pregnant women (3)[A]
  - There is a lack of evidence on whether antenatal treatment reduces congenital transmission; however, prenatal treatment is usually offered.
  - <18 weeks' gestation: Spiramycin 1 g PO q8h without food until delivery if amniotic fluid PCR is negative. Does not treat infection in the fetus
  - >18 weeks' gestation: Pyrimethamine and sulfadiazine should be considered only if fetal infection is documented by positive amniotic fluid PCR (pyrimethamine is teratogenic):

- Pyrimethamine: 50 mg PO q12h for 2 days, then 50 mg/day plus sulfadiazine 75 mg/kg PO ÷ 1 dose, then 50 mg/kg q12h (max 4 g/day)
- Treat infected newborns regardless of clinical manifestations:
  - Pyrimethamine 2 mg/kg/day (max 50 mg) for 2 days; then 1 mg/kg/day (max 25 mg) for 2 to 6 month; then 1 mg/kg (max 25 mg) on Monday, Wednesday, and Friday; sulfadiazine 100 mg/kg/day divided BID; and leucovorin 10 mg three times per week during pyrimethamine and 1 week after discontinuation
- Immunocompetent nonpregnant patients generally do not require treatment unless symptoms are severe or prolonged; 1 of 2 regimens can be used:
  - Pyrimethamine: 100 mg loading dose PO, followed by 25 to 50 mg/day *plus* sulfadiazine 2 to 4 g/day in four divided doses
  - Pyrimethamine: 100 mg loading dose PO, followed by 25 to 50 mg/day *plus* clindamycin 300 mg PO QID

## Second Line

- Clindamycin: 900 to 1,200 mg TID IV used for ocular and CNS toxoplasmosis alone and in combination with pyrimethamine; as effective as the sulfadiazine-pyrimethamine with fewer adverse effects
- Corticosteroids (prednisone 1 to 2 mg/kg/day) are added for macular chorioretinitis or CNS infection.
- Alternatives: atovaquone (Mepron), azithromycin (Zithromax), clarithromycin (Biaxin), or dapsone *plus* pyrimethamine and leucovorin
- Trimethoprim-sulfamethoxazole appears to be equivalent to pyrimethamine-sulfadiazine in AIDS patients with CNS disease.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### Patient Monitoring

##### Precautions

- Monitor for bone marrow, renal, or liver toxicity.
- Good hydration: Sulfadiazine is poorly soluble and may crystallize in the urine.

- Watch for antibiotic-associated diarrhea.
- Sulfonamides may alter phenytoin and warfarin levels or interfere with oral hypoglycemic agents.

## PATIENT EDUCATION

- <http://www.aafp.org/afp/2003/0515/p2145.html>
- <http://familydoctor.org/familydoctor/en/diseases-conditions/toxoplasmosis.html>

## PROGNOSIS

- Immunodeficient patients often relapse if treatment or suppression therapy is stopped.
- Treatment may prevent the development of untoward sequelae in infants with congenital toxoplasmosis.

## Codes

**&NA;**

### ICD10

- B58.9 Toxoplasmosis, unspecified
- P37.1 Congenital toxoplasmosis
- B58.2 Toxoplasma meningoencephalitis

## Clinical Pearls

**&NA;**

- Toxoplasmosis is often asymptomatic in immunocompetent patients, who often don't need treatment for clinical disease.
- Primary prevention is important, particularly for pregnant women and immunodeficient patients.
- The most common manifestation of acute toxoplasmosis in immunocompetent host is bilateral, symmetric, nontender cervical lymphadenopathy.
- Universal screening for congenital toxoplasmosis is not currently recommended.

# Tracheitis, Bacterial

Mary Cataletto, MD, FAAP, FCCP

## BASICS

### DESCRIPTION

- Acute, potentially life-threatening infraglottic bacterial infection following a primary viral infection, usually parainfluenzae or influenza viruses
  - Direct laryngoscopy reveals marked subglottic edema and thick mucopurulent secretions, sometimes causing pseudomembranes.
- System(s) affected: pulmonary
- Synonym(s): laryngotracheobronchitis; pseudomembranous croup; bacterial croup

### EPIDEMIOLOGY

#### Incidence

- Estimated incidence: 4 to 8 per 1,000,000 (1)
- First cases described prior to 1950; resurgence of cases has been noted since 1979.
- Peak incidence in children: fall and winter
- Mean age: 5 years (1)
- Infections in adolescents and adults have been reported.
- Predominant sex: male > female (2:1)
- Accounts for 5-14% of upper airway obstruction in children requiring critical care services

#### Prevalence

- Rare illness
- Most common potentially life-threatening upper airway infection in children
- Methicillin-resistant *Staphylococcus aureus* (MSRA) may contribute to changing epidemiology and virulence.

## ETIOLOGY AND PATHOPHYSIOLOGY

- *Staphylococcus aureus* (most common pediatric cause): Consider MRSA.
- *Haemophilus influenzae* type B
- *Streptococcus pyogenes* group A
- *Streptococcus pneumoniae*
- *Moraxella catarrhalis* (associated with higher intubation rate; more frequent in younger children)
- Often polymicrobial

## Genetics

No known genetic predisposition

## RISK FACTORS

- Periods of increased seasonal activity of respiratory viruses
- Reports following adenoidectomy, with chronic tracheal aspiration, with evidence of other concurrent infections, including sinusitis, otitis, pneumonia, or pharyngitis

## GENERAL PREVENTION

- Standard precautions, with scrupulous attention to hand washing, especially when caring for tracheostomy patients
- Vaccination against viruses that may predispose to bacterial tracheitis

## COMMONLY ASSOCIATED CONDITIONS

- Consider anatomic abnormalities or foreign body as well as recent pharyngeal or laryngeal surgery.
- Predisposing: Down syndrome, immunodeficiency, subglottic hemangioma, tracheoesophageal fistula repair, tracheobronchomalacia
- Viral coinfection may occur.

## DIAGNOSIS

- May present with fever and systemic toxicity or as more localized disease
- Careful history and physical exam are the best methods to distinguish bacterial tracheitis from

croup and other rare causes of upper airway obstruction.

## **HISTORY**

- Prodromal upper respiratory tract symptoms
- Gradual progression of mild upper airway symptoms over 1 hour to 6 days to acute, febrile phase of rapid respiratory decompensation
- No drooling
- No response to aerosolized epinephrine and/or systemic corticosteroids (1)

## **PHYSICAL EXAM**

FEVER >38;C (100.4;F)

- Toxic appearance
- Variable degree of respiratory distress (2)
  - Tachypnea
  - Inspiratory stridor (2)
- Voice and cry usually normal
- Drooling uncommon

## **DIFFERENTIAL DIAGNOSIS**

- Severe croup (viral)
- Spasmodic croup
- Diphtheria in nonvaccinated patients
- Retropharyngeal abscess
- Epiglottitis
- Pneumonia
- Foreign body aspiration

## **DIAGNOSTIC TESTS & INTERPRETATION**

- Routine laboratory studies are not required to make the diagnosis.
- Radiographs are neither definitive nor diagnostic.
- Tracheal endoscopy provides a definitive diagnosis (1,3)[C].

## *Initial Tests (lab, imaging)*

- Bacterial cultures of tracheal secretions are required for culture isolates and sensitivities.
- Rapid antigen or polymerase chain reaction (PCR)-based testing for respiratory viruses may be helpful.
- Routine laboratory studies may not be helpful.
- Blood cultures rarely positive
- CBC results may vary.
  - WBC count may show marked leukocytosis or may be normal.
  - Increased band cell count
- Radiographs may be normal, but exudates may mimic the findings in foreign body aspiration.
- Pneumonic infiltrates are common.
- Anteroposterior (AP) and lateral neck x-rays show subglottic and tracheal narrowing (i.e., steeple sign on AP film) with haziness and radiopaque linear or particulate densities (crusts).
- In patients with risk of acute respiratory obstruction, either do not obtain x-rays or monitor carefully.

## *Follow-Up Tests & Special Considerations*

Follow chest film if suspect pneumonia.

## *Diagnostic Procedures/Other*

- Direct laryngoscopy and tracheoscopy is diagnostic and demonstrates
  - Normal supraglottic structures
  - Marked subglottic erythema and edema
  - Ulcerations
  - Epithelial sloughing
  - Copious mucopurulent secretions ± plaques or pseudomembranes
- Obtain Gram stain and aerobic, anaerobic, and viral cultures of tracheal secretions during the procedure.

## *Test Interpretation*

- Tracheal biopsy is rarely indicated but may be considered in immunodeficient child or child

with ulcerative colitis.

- Diffuse inflammation of larynx, trachea, and bronchi
- Mucopurulent exudate; microabscesses may be present.
- Semiadherent membranes (containing numerous neutrophils and cellular debris) may be identified within the trachea.

## TREATMENT

- Treat as potentially life-threatening airway emergency.
- Children with suspected or actual bacterial tracheitis should be cared for in a pediatric ICU (1) [C].
- Assess and monitor respiratory status; supplemental oxygen may be required.
- Airway protection and support, as necessary (at least 50% require intubation; some studies report up to 100%)
- Ventilatory support may be required.
- Suctioning
- Different clinical course in previously healthy children compared with those with artificial airway

---

P.1053

## MEDICATION

- Empiric therapy should cover the most common pathogens until sensitivities are available: antistaphylococcal agent (vancomycin or clindamycin) and a 3rd-generation cephalosporin (e.g., ceftriaxone or cefotaxime) (1,3)[C].
- In the case of technology-dependent children with tracheostomy, make initial antibiotic choices based on previous tracheal culture.
- Narrow regimen when pathogens and sensitivities available (1,3)[C]
- Contraindications: Refer to the manufacturer's literature for each drug.
- Precautions: Refer to the manufacturer's literature for each drug. Avoid aminoglycosides in patients with previous hearing loss.
- Significant possible interactions: Refer to the manufacturer's literature for each drug.

## ISSUES FOR REFERRAL

All children with suspected or actual bacterial tracheitis should be cared for in a pediatric ICU by a pediatric critical care team that may include the following subspecialists: pediatric intensivist, infectious disease specialist, pulmonologist, and/or otolaryngologist.

## ***ADDITIONAL THERAPIES***

- At present, evidence is lacking to establish the effect of heliox inhalation in the treatment of croup in children.
- For technology-dependent children with artificial airway:
  - Initial antibiotic choices should cover most recent tracheal aspirate isolates and then be refined according to culture and sensitivity results.
  - Adjunctive aerosol therapy may be helpful, particularly when multidrug-resistant organisms are present.

## ***SURGERY/OTHER PROCEDURES***

- Tracheostomy is usually not necessary.
- Therapeutic bronchoscopy may be necessary to facilitate removal of inspissated secretions.
- Tracheal membranes may require removal.

## ***INPATIENT CONSIDERATIONS***

- Aggressive supportive care and airway protection are paramount.
- Initial treatment of choice for bacterial tracheitis is broad-spectrum antibiotic coverage.
- Children with tracheitis and artificial airways present unique challenges: Tracheoscopy is important in establishing diagnosis in this population.
- Be vigilant for possible MRSA.

## ***Pediatric Considerations***

- True pediatric emergency
- Admission to ICU
- Maintain airway: often difficult due to copious secretions
  - Endotracheal or nasotracheal intubation usually needed, especially in infants and children <4 years of age
  - Much less likely to need intubation if child >8 years of age

Advantage of intubation is the ability to clear trachea and bronchi of secretions and pseudomembranes.

- Vigorous pulmonary toilet to clear airway of secretions
- Hydration, humidification, antibiotics

### *Admission Criteria/Initial Stabilization*

- Suspected or confirmed diagnosis of tracheitis
- Respiratory distress
- Artificial airway

### *Nursing*

- Provide calm, quiet environment for child once endoscopy and cultures are done.
- Airway monitoring
- Frequent suctioning
- Monitor fluid balance.
- Establish and maintain open lines of communication with child and parents.

### *Discharge Criteria*

No longer in need of acute care

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### **Patient Monitoring**

Children with artificial airways will require ongoing follow-up.

#### **DIET**

Varies with clinical situation

#### **PATIENT EDUCATION**

Keep immunizations up to date.

#### **PROGNOSIS**

- Intubation generally 3 to 11 days
- Usually requires 3 to 7 days of hospitalization
- With effective early recognition and management, complete recovery can be expected.
- Cardiopulmonary arrest and death have occurred.

## COMPLICATIONS

- Cardiopulmonary arrest
- Hypotension
- Acute respiratory distress syndrome (ARDS)
- Pneumonia
- Formation of pseudomembranes

## Codes

**&NA;**

### ICD10

- J04.10 Acute tracheitis without obstruction
- J04.11 Acute tracheitis with obstruction
- J05.0 Acute obstructive laryngitis [croup]

## Clinical Pearls

**&NA;**

- Bacterial tracheitis is an acute, potentially lifethreatening, infraglottic bacterial infection following a primary viral infection that accounts for 5-14% of upper airway obstructions in children requiring critical care services.
- Children with suspected or actual bacterial tracheitis should be cared for in a pediatric ICU.
- Endoscopy provides a definitive diagnosis (2).
- Initial treatment of choice for bacterial tracheitis is broad-spectrum antibiotic coverage, aggressive airway protection, and supportive care (2).

# TRANSIENT ISCHEMIC ATTACK (TIA)

Emilio A. Russo, MD

G. Daud Noaz, MD, MSBME

## BASICS

### DESCRIPTION

- A transient episode of neurologic dysfunction due to focal brain, retinal, or spinal cord ischemia without acute infarction
- No longer diagnosed based on timeframe of symptoms
- Most important predictor of stroke: 7-40% of patients with stroke report previous TIA.
- Synonym(s): ministroke

### EPIDEMIOLOGY

- Incidence of TIA underestimated because some patients do not report symptoms.
- 200,000 to 500,000 new TIA cases reported each year
  - 83 cases/100,000 people/year in the United States
  - 400 to 800 cases/100,000 persons aged 50 to 59 years
- Prevalence of TIA in general population: ÷ 2.3%
- Predominant age: risk increases >60 years; highest in 7th and 8th decades
- Predominant sex: male > female (3:1)
- Predominant race/ethnicity: African Americans > Hispanics > Caucasians. The difference in African Americans is exaggerated at younger ages.

### ETIOLOGY AND PATHOPHYSIOLOGY

Temporary reduction/cessation of cerebral blood flow adversely affecting neuronal function

- Carotid/vertebral atherosclerotic disease
  - Artery-to-artery thromboembolism
  - Low-flow ischemia

- Small, deep vessel disease associated with HTN
  - Lacunar infarcts
- Cardiac diseases
  - 1-6% of patients with MI develop stroke.
- Embolism secondary to the following:
  - Valvular (mitral valve) pathology
  - Mural hypokinesias/akinesias with thrombosis (acute anterior MI/congestive cardiomyopathies)
  - Cardiac arrhythmia (atrial fibrillation accounts for 5-20% incidence)
- Hypercoagulable states
  - Antiphospholipid antibodies
  - Deficiency of protein S, protein C
  - Presence of antithrombin III
  - Oral contraceptives
  - Pregnancy and parturition
- Arteritis
  - Noninfectious necrotizing vasculitis
  - Drugs
  - Irradiation
  - Local trauma
- Sympathomimetic drugs (e.g., cocaine)
- Other causes: spontaneous and posttraumatic (e.g., chiropractic manipulation) arterial dissection
- Fibromuscular dysplasia

## *Genetics*

Inheritance is polygenic, with tendency to clustering of risk factors within families.

## **RISK FACTORS**

- Hypertension (HTN)
- Cardiac diseases (A-fib, MI, valvular disease)
- Diabetes
- Hyperlipidemia
- Atherosclerotic disease (carotid/vertebral stenosis)
- Cigarette smoking
- Thrombophilias

## GENERAL PREVENTION

- Lifestyle changes: smoking cessation, diet modification, weight loss, regular aerobic exercise, and limited alcohol intake
- Use of ASA and statins as primary prevention may be considered in certain populations.
- Strict control of medical risk factors: *diabetes* (glycemic control), *HTN* (thiazide and/or ACE/ARB), *hyperlipidemia* (statins), anticoagulation when high risk of cardioembolism (e.g., atrial fibrillation, mechanical valves)

### **ALERT**

10-20% of patients with TIA have CVA within 90 days; 25-50% of those occur within the first 48 hours.

### *Geriatric Considerations*

- Older patients have a higher mortality rate than younger patients—highest in 7th and 8th decades.
- Atrial fibrillation is a frequent cause among the elderly.

### *Pediatric Considerations*

- Congenital heart disease is a common cause among pediatric patients.
- Other causes include the following:
  - Metabolic: homocystinuria, Fabry disease
  - Central nervous system (CNS) infection
  - Clotting disorders
  - Marfan syndrome

- Moyamoya disease

## *Pregnancy Considerations*

- Preeclampsia, eclampsia, and HELLP
- TTP and hemolytic uremic syndrome
- Postpartum angiopathy
- Cerebral venous thrombosis
- Hypercoagulable states related to pregnancy

## **COMMONLY ASSOCIATED CONDITIONS**

- Atrial fibrillation
- Uncontrolled HTN
- Carotid stenosis

## **DIAGNOSIS**

### **HISTORY**

- Obtain witness accounts with emphasis on symptom onset, progression, and recovery.
- Carotid circulation (hemispheric): monocular visual loss, hemiplegia, hemianesthesia, neglect, aphasia, visual field defects (amaurosis fugax); less often, headaches, seizures, amnesia, confusion
- Vertebrobasilar (brain stem/cerebellar): bilateral visual obscuration, diplopia, vertigo, ataxia, facial paresis, Horner syndrome, dysphagia, dysarthria; also headache, nausea, vomiting, and ataxia
- Past medical history, baseline functional status
- ABCD2 score: predicts risk of CVA within 48 hours (1)[A]
  - Score of 0 to 1: 0%; 2 to 3: 1.3%; 4 to 5: 4.1%; 6 to 7: 8.1%
  - **Age** >65 years: 1 point
  - **BP** 140/90 mm Hg: 1 point
  - Symptoms of focal weakness: 2 points
  - Speech impaired without weakness: 1 point
  - **Duration** >60 minutes: 2 points

- **Duration 10 to 59 minutes:** 1 point
- **Diabetes:** 1 point

## *PHYSICAL EXAM*

- Vital signs, oxygen saturation
- Thorough neurologic and cardiac exams
- ABCD2 score:

## *DIFFERENTIAL DIAGNOSIS*

- Evolving stroke
- Migraine (hemiplegic)
- Focal seizure (Todd paralysis)
- Hypoglycemia
- Bell palsy
- Neoplasm of brain
- Subarachnoid hemorrhage
- Intoxication
- Electrolyte abnormalities

## *DIAGNOSTIC TESTS & INTERPRETATION*

### **Initial Tests (lab, imaging)**

- Patients with TIA should undergo neuroimaging evaluation within 24 hours of symptom onset.
- MRI, including diffusion-weighted imaging, is the preferred brain diagnostic modality; if not available then noncontrast head CT (2)[B].
- Noninvasive imaging of the cervicocephalic vessels should be performed routinely as part of the evaluation of suspected TIA (2)[A].
- Initial assessment of the extracranial vasculature may involve carotid US/TCD, MRA, or CTA depending on the availability and expertise and characteristics of the patient (2)[B].
- Routine blood tests (CBC, chemistry, PT/PTT, UPT, and fasting lipid panel) are reasonable in evaluation of patient with TIA (2)[B].

## *Follow-Up Tests & Special Considerations*

- If only noninvasive testing is performed prior to CEA, it is reasonable to pursue two concordant noninvasive findings; otherwise, catheter angiography should be considered (2)[B].
- Echo is reasonable in evaluation of patients with suspected TIA especially when no other cause is noted (2)[B].
- TEE is useful in identifying PFO, aortic arch atherosclerosis, and valvular disease and is reasonable when this will alter management (2)[B].
- Prolonged cardiac monitoring is useful in patients with an unclear etiology after initial brain imaging and ECG (2)[B].
- EEG: if seizure suspected
- After TIA, all patients should be screened for DM with either fasting plasma glucose or hemoglobin A1C.
- Consider a sleep study due to the high prevalence of sleep apnea among TIA patients; treatment with CPAP has shown to improve patient outcomes (3)[B].

## **TREATMENT**

### *GENERAL MEASURES*

- TIA is a neurologic emergency. Immediate medical attention should be sought within 24 hours of symptom onset.
- Current evidence suggests that patients with high-risk TIAs require rapid referral and 24-hour admission (see ABCD2 scoring).
- Acute phase
  - Inpatient for surgery and high-risk groups
  - Outpatient investigations may be considered based on patient's stroke risk, arrangement of follow-up, and social circumstances.
- Antiplatelet therapy to prevent recurrence or future CVA
- Treatment/control of underlying associated conditions

### *MEDICATION*

- For patients with TIA, the use of antiplatelet agents rather than oral anticoagulation is

recommended to reduce risk of recurrent stroke and other cardiovascular events, with the exception of cardioembolic etiologies (2)[A].

- *Uncertain* if switching agent in patients who have additional ischemic attacks while on antiplatelet therapy is beneficial (4)[C].

## *First Line*

- Enteric-coated aspirin: 160 to 325 mg/day in the acute phase (5)[A] followed by long-term antiplatelet therapy for noncardioembolic TIA and anticoagulation for cardioembolic etiology
- Antiplatelet therapy
  - ER dipyridamole-ASA (Aggrenox): 25/200 mg BID (4,6)[B]
  - Combined therapy with dipyridamole and ASA is better than ASA alone (5,7)[A].
  - More expensive than ASA alone and may have more side effects
  - Aspirin 50 to 325 mg/day (4)[A]
    - Contraindications: active PUD and hypersensitivity to ASA or NSAIDs
    - Precautions: may aggravate preexisting peptic ulcer disease; may worsen symptoms of asthma
    - Significant possible interactions: may potentiate effects of anticoagulants and sulfonyleurea analogues
  - Clopidogrel 75 mg/day (4)[B]
    - Can be used in patients who are allergic to ASA (4)[B]
    - Precautions: Thrombotic thrombocytopenic purpura (TTP) can occur and increases risk of bleeding when combined with aspirin.
    - May be very slightly more effective than aspirin alone (5)[B]; more expensive and more side effects than aspirin
- Combined aspirin and clopidogrel therapy has been demonstrated to reduce the incidence of subsequent stroke by 21% without increased risk of bleeding when used for a duration of 1 month or less immediately following TIA or CVA (6)[A].
- Anticoagulation therapy
  - Factor Xa inhibitors (rivaroxaban, apixaban), direct thrombin inhibitor (dabigatran)
    - Noninferior to warfarin in nonvalvular A-fib
    - Precautions: avoid in CKD (CrCl <30 mL/min)

- Expensive
- Warfarin (INR-adjusted dose) (4)[A]
  - Contraindications: intolerance/allergy, active liver disease, active bleeding, pregnancy
  - Significant possible interactions: antibiotics, antiepileptics, antifungals, and many others
- ASA 325 mg/day or ASA 81 mg/day and clopidogrel 75 mg/day (4)[A]
  - Patients who cannot take anticoagulation for reasons other than bleeding risk

## *Second Line*

Ticlopidine (Ticlid): 250 mg PO BID

- For patients who cannot tolerate other agents
- Contraindications: hypersensitivity, presence of hematopoietic/hemostatic disorders, conditions associated with bleeding, severe liver dysfunction
- Precautions: neutropenia (0.8% severe), which is reversible with cessation of the drug. Monitor blood counts every 2 weeks for first 3 months. TTP can occur.
- Significant possible interactions: Digoxin plasma levels decreased 15%; theophylline half-life increased from 8.6 to 12.2 hours.

## *ISSUES FOR REFERRAL*

- Neurology for ongoing workup and treatment
- Cardiology if cardiac cause suspected
- Vascular surgery if carotid endarterectomy appropriate

## *ADDITIONAL THERAPIES*

- Secondary prevention of TIA should be initiated; venous thromboembolism (VTE) prophylaxis
- Patients with TIA or ischemic stroke should be started on a statin.
- BP should be reduced when appropriate after 24 hours. ACE inhibitors/thiazide have shown to be of benefit.
- Patients with DM or pre-DM should be advised to follow ADA guidelines to maintain tight glycemic control (3)[A].

## *SURGERY/OTHER PROCEDURES*

Consider carotid endarterectomy in patients with a high degree of carotid artery stenosis.

- When carotid endarterectomy is indicated for patients with TIA, surgery within 2 weeks is reasonable if there are no contraindications to early revascularization.

## *INPATIENT CONSIDERATIONS*

### **Admission Criteria/Initial Stabilization**

- Symptoms <72 hours and the following:
  - ABCD2 score of  $\geq 3$
  - ABCD2 score of 0 to 2 and uncertainty that dx workup can be completed within 2 days as outpatient.
  - ABCD2 score of 0 to 2 and evidence that indicates the patient's event was caused by focal ischemia.
- Correct fluid and electrolyte imbalances.

### *Discharge Criteria*

Consider safety at home if another incident occurs.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### **Patient Monitoring**

- Follow-up every 3 months for 1st year then annually
- Close attention to recurrent or subsequent CVA

### *DIET*

- As appropriate for underlying medical problems

## *PROGNOSIS*

- The risk of stroke on the ipsilateral side within 90 days and cumulative thereafter is 10-20%.
- Frequency increases with the addition of multiple risk factors and severity of carotid stenosis.
- Patients with larger artery occlusion or cardioembolic etiology are at increased risk of recurrence.

- The major cause of death in the first 5 years is cardiac disease.

## COMPLICATIONS

- Stroke
- Functional impairment

## Codes

**&NA;**

### ICD10

- G45.9 Transient cerebral ischemic attack, unspecified
- G45.1 Carotid artery syndrome (hemispheric)
- G45.0 Vertebro-basilar artery syndrome

## Clinical Pearls

**&NA;**

- Primary/secondary prevention is important, stressing smoking cessation, exercise, weight loss, limited ETOH intake, and control of HTN, hyperlipidemia, and diabetes.
- Antiplatelet therapy (e.g., aspirin or clopidogrel or aspirin-dipyridamole) should be initiated.
- Warfarin should be initiated in patients with atrial fibrillation or cardioembolic risk factors.
- A 30% risk of stroke exists within 5 years of a TIA.

# Transient Stress Cardiomyopathy

Timothy P. Fitzgibbons, MD, PhD

Gerard P. Aurigemma, MD

## BASICS

### DESCRIPTION

- Transient stress cardiomyopathy (TSC) is a unique cause of reversible left ventricle (LV) dysfunction with a presentation indistinguishable from the acute coronary syndromes (ACS), particularly ST-segment elevation myocardial infarction (MI) (1).
- Typically, the patient is a postmenopausal woman who presents with acute chest pain or dyspnea after an identifiable trigger (i.e., an acute emotional or physiologic stressor).
- First reported by authors from Japan, TSC was known initially as the *takotsubo syndrome* because the typical LV morphology (i.e., apical ballooning) resembled that of a Japanese octopus trap or *takotsubo* (2)[B].
- Presenting clinical features include the following:
  - Chest symptoms and/or dyspnea
  - ECG changes, including ST-segment elevations or diffuse T-wave inversions
  - Mild elevation in cardiac biomarkers (creatinine kinase [CK], troponin)
  - Transient wall motion abnormalities that may involve the base, midportion, and/or lateral walls of the LV.
  - The apex of the right ventricle (RV) may be affected in up to 25% of cases (3)[B].
- Clinical features may vary on a case-by-case basis, and formal diagnostic criteria have not been established.
- Authors from the Mayo Clinic have proposed that 3 of the 4 following criteria establish the diagnosis (1)[A]:
  - Transient akinesis or dyskinesis of the LV apical and midventricular segments with regional wall motion abnormalities extending beyond a single epicardial vascular distribution
  - Absence of obstructive coronary artery disease (CAD) or angiographic evidence of acute plaque rupture

- New ECG abnormalities, either ST-segment elevation or T-wave inversion
- Absence of
- Recent significant head trauma
- Intracranial bleeding
- Pheochromocytoma
- Obstructive epicardial CAD
- Myocarditis
- Hypertrophic cardiomyopathy
- Synonym(s): takotsubo cardiomyopathy; apical ballooning syndrome; stress cardiomyopathy; broken heart syndrome; ampulla cardiomyopathy

## *EPIDEMIOLOGY*

### **Incidence**

- TSC accounts for a small percentage (1-3%) of ACS.
- In a recent prospective evaluation of patients admitted to the ICU, as many as 28% had apical ballooning, often in association with sepsis.
- Predominant sex: 82-100% of cases occur in women.
- Predominant age: Mean age of patients is 62 to 75 years.

### *Prevalence*

2.2% of patients presenting to a referral hospital with ST-segment MIs were found to have TSC.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- The exact pathophysiology is not known.
- A perturbation in the brain-heart axis, originating in the insular cortex, may be the inciting event (4).
- Subsequent overwhelming activation of the sympathetic nervous system initiates a cascade of events, including the following:
  - Catecholamine-induced LV dysfunction: Biased agonism of epinephrine for  $\beta_2$ -adrenergic receptors, located predominantly at the cardiac apex (5)
  - Endothelial dysfunction and vasospasm

- Cellular metabolic injury
- Myocardial norepinephrine release
- Calcium overload
- Contraction band necrosis

## *Genetics*

No genetic associations have been described to date.

## **RISK FACTORS**

- Female sex
- Postmenopausal state
- Emotional stress (i.e., argument, death of family member)
- Physiologic stress (i.e., acute medical illness)
- Chronic neurologic or psychiatric disease (4)

## **COMMONLY ASSOCIATED CONDITIONS**

Death from TSC is rare, and most cases resolve rapidly, within 2 to 3 days. Reported complications include:

- Left-sided heart failure
- Pulmonary edema
- Cardiogenic shock and hemodynamic compromise
- Dynamic LV outflow tract gradient complicated by hypotension
- Mitral regurgitation
- Ventricular arrhythmias
- LV thrombus formation
- LV free wall rupture
- Death (rare, 0-8%)

## **DIAGNOSIS**

Because TSC often is indistinguishable from an ACS, it should be treated initially as such:

- Activate emergency medical services or report to emergency department.
- Oxygen, IV access, and ECG monitoring
- Urgent cardiology consultation

## **HISTORY**

- In 2/3 of patients, there is exposure to a “trigger event.”
  - Emotional stress: argument, death of family member, divorce, public speaking, and so forth
  - Physiologic stress: acute medical condition such as head trauma, asthma attack, seizure, and so forth
    - In 1/3 of patients, there is no identifiable trigger (4).
    - Acute onset of dyspnea or chest pain
    - Palpitations
    - Syncope

## **PHYSICAL EXAM**

Exam may be unremarkable or may include any of the following:

- Tachypnea
- Tachycardia
- Hypotension
- Jugular venous distension
- Bibasilar rales
- S<sub>3</sub> gallop
- Systolic ejection murmur due to dynamic LV outflow tract gradient
- Holosystolic murmur of mitral regurgitation

## **DIFFERENTIAL DIAGNOSIS**

- Acute ST-segment elevation MI
- Pulmonary embolism
- Myopericarditis
- Pheochromocytoma

- Hypertrophic cardiomyopathy
- Subarachnoid hemorrhage or stroke

## *DIAGNOSTIC TESTS & INTERPRETATION*

- ECG should be done urgently and may show the following:
  - Diffuse ST-segment elevations
  - Diffuse and often dramatic T-wave inversions
  - QTc interval prolongation (6)[B]
  - Q waves
- Laboratory tests typically reveal a mild elevation in cardiac biomarkers such as
  - CK (rarely > 500 U/mL)
  - Troponin I
  - B-type natriuretic peptide (BNP)
  - Markers of high filling pressures (e.g., BNP) tend to be higher than markers of necrosis (e.g., CK, troponin).
  - TSC can be distinguished from AMI with 95% specificity using a BNP/TnT ratio >1,272 (sensitivity 52%) (7)[B].
- Chest radiograph
  - Cardiomegaly
  - Pulmonary edema
- Echocardiogram
  - Reduced LV systolic function
  - Abnormal diastolic function, including evidence of increased filling pressures
  - Regional wall motion abnormalities in one of the following patterns:
    - Classic or Takotsubo-type ballooning of the apex with a hypercontractile base
    - Reverse takotsubo: apical hypercontractility with basal akinesis
    - Midventricular akinesis with apical and basal hypercontractility
    - Focal or localized akinesis of an isolated segment
  - Dynamic intracavitary LV gradient

- Mitral regurgitation
- Variable involvement of the RV
- Cardiac MRI
  - Reduced LV function
  - Wall motion abnormalities as described for transthoracic echocardiography
  - Absence of delayed hyperenhancement with gadolinium

## Diagnostic Procedures/Other

- Because ST-segment elevation MI is the diagnosis of exclusion, patients typically are referred for urgent cardiac catheterization.
- Coronary angiography
  - Nonocclusive CAD
  - Rarely, epicardial coronary spasm
  - Endothelial dysfunction as measured by fractional flow reserve or TIMI frame counts
- Left-sided heart catheterization: increased LV enddiastolic pressure to a similar degree as AMI (8)[B]
- Ventriculography: wall motion abnormalities as described for transthoracic echocardiography
- Right-sided heart catheterization
  - Increased pulmonary capillary wedge pressure
  - Secondary pulmonary hypertension
  - Increased right ventricular filling pressures
  - Reduced cardiac output or cardiogenic shock (cardiac index  $<2$  and mean arterial pressure [MAP]  $<60$  mm Hg)

## Test Interpretation

Characteristic pathologic findings of involved myocardium have not been described.

## TREATMENT

- Activation of emergency medical services

- Advanced cardiac life support therapies as needed
- Oxygen
- IV access
- ECG monitoring

## **MEDICATION**

After diagnostic cardiac catheterization, empirical treatment goals are as follows:

- Management of hypotension: differentiation between cardiogenic shock and dynamic LV cavity gradient
- Management of increased filling pressures and congestive states
- Attenuation of sympathetic drive

### **First Line**

- There are no evidence-based treatment recommendations for TSC.
- Although *β*-blockers are of theoretical benefit, their use has not been associated with improved outcomes in observational cohorts (4)[B].
- If there is evidence of left ventricular systolic dysfunction or pulmonary edema, consider the following:
  - Furosemide: 20 to 40 mg IV/PO BID as needed to reduce LV filling pressures and dyspnea (9)
  - ACE inhibitors or angiotensin receptor blockers: Lisinopril 10 to 40 mg/day PO or equivalent or valsartan 80 to 160 mg PO BID have been associated with improved outcomes in observational cohorts (4)[B].

### **Second Line**

Short-term anticoagulation should be considered in patients with severely reduced LV function to prevent LV thrombus formation. Unfractionated heparin 80 U/kg IV bolus followed by 18 U/kg/hr IV or Lovenox 1 mg/kg SC BID.

## **ISSUES FOR REFERRAL**

All patients with TSC generally should be comanaged with cardiology while inpatient and referred to cardiology as an outpatient.

## ***ADDITIONAL THERAPIES***

- Urgent cardiology consultation and consideration of cardiac catheterization
- Hypotension may require the following:
  - Vasopressors (e.g., dopamine or Levophed) if there is no LV outflow tract gradient (9)[C]
  - Phenylephrine and IV fluids to increase afterload in the presence of an LV outflow tract gradient (9)[C]
  - Cardiogenic shock that is not due to an LV outflow tract gradient may require placement of an intra-aortic balloon pump.

## ***INPATIENT CONSIDERATIONS***

### **Admission Criteria/Initial Stabilization**

- 12-lead ECG
- Chest radiograph
- Laboratory testing
- Echocardiography
- Patients with TSC usually are admitted for observation because the differential diagnosis includes ACS.

### ***IV Fluids***

Normal saline infusion to support BP, if necessary, and no evidence of heart failure

### ***Discharge Criteria***

Generally considered after exclusion of ACS and resolution of

- Congestive state
- Hypotension
- Profound impairments of systolic function

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Impairments in systolic function typically resolve in 2 to 3 days but may last as long as 1

month.

- Patients should follow up with cardiology and serial echocardiography to document improved LV function.

## PROGNOSIS

- Prognosis is excellent. Inpatient mortality is rare and ranges from 0% to 8%.
- Recurrence is rare; it also has been reported in 0-8% of patients.

### ICD10

I51.81 Takotsubo syndrome

## Clinical Pearls

&NA;

- TSC is a cause of reversible LV dysfunction with a clinical presentation indistinguishable from the ACS, particularly ST-segment elevation MI.
- Echocardiography may strongly suggest the diagnosis.
- Treatment is supportive and should include diuretics and ACE inhibitors in patients with CHF.

# Trichomoniasis

Michael Arnold, MD, CDR, MC

Joshua R. Beer, DO

## BASICS

### DESCRIPTION

- Sexually transmitted urogenital infection caused by a pear-shaped, parasitic protozoan
- Causes vaginitis/urethritis in women, nongonococcal urethritis in men
- In pregnancy, increases risk of preterm labor, preterm premature rupture of membranes, small for gestational age infant, and possibly stillbirth
- Synonym(s): trich; trichomonal urethritis

### EPIDEMIOLOGY

#### Incidence

- Affects >120 million women worldwide. The most common curable sexually transmitted infection (STI) worldwide (1).
- Estimated 1.1 million new cases annually in the United States
- 10-25% of vaginal infections
- 1-17% of cases of NGU in males; reported prevalence among men without urethritis ranges from 0% to 8%
- Predominant age: middle-aged adults
  - Rare until onset of sexual activity
  - Common in postmenopausal women; age is not protective and long-term carriage is possible.
- Women have higher prevalence (1.5 to 4.4 times more than men) and are more commonly symptomatic (2).

### Pediatric Considerations

Rare in prepubertal children; diagnosis should raise concern of sexual abuse.

## *Prevalence*

- 3.1% of all U.S. women age 25 to 49 years; 1.5% of U.S. women age 15 to 24 years
- Racial disparity demonstrated
  - 1.3% of white, non-Hispanic women
  - 1.8% of Mexican American women
  - 13.3% of black, non-Hispanic women (2)

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- *Trichomonas vaginalis*: a pear-shaped, flagellated, parasitic protozoan
- Grows best at 35-37°C in anaerobic conditions at pH of 5.5 to 6.0
- STI, but nonsexual transmission is possible because organism can survive several hours in moist environment.

## *Genetics*

No known genetic considerations

## *RISK FACTORS*

- Multiple sexual partners
- Unprotected intercourse
- Lower socioeconomic status
- Other STIs
- Untreated partner with previous infection
- Use of douching or feminine powders

## *GENERAL PREVENTION*

- Use of male or female condoms
- Limiting numbers of sexual partners
- Male circumcision may be protective (3)[B].

## *COMMONLY ASSOCIATED CONDITIONS*

- Other STIs, including HIV
- Bacterial vaginosis

## DIAGNOSIS

### HISTORY

- Women
  - Yellow-green, malodorous vaginal discharge
  - Vulvovaginal pruritus
  - Dysuria
  - 70-85% are symptomatic.
- Men
  - Dysuria
  - Urethral discharge
  - 80% are asymptomatic.

### PHYSICAL EXAM

- Women
  - Vaginal erythema
  - Yellow-green, frothy, malodorous vaginal discharge
  - Cervical petechiae (strawberry cervix; seen in ÷ 10% of patients)
- Men: penile discharge, spontaneous and with expression

### DIFFERENTIAL DIAGNOSIS

- Women (other vaginitides)
  - Bacterial vaginosis
  - Vaginal candidiasis
  - Chlamydial infection
  - Gonorrheal infection
- Men (other urethritides)
  - Chlamydial infection

- Gonorrhoeal infection

## *DIAGNOSTIC TESTS & INTERPRETATION*

### **Initial Tests (lab, imaging)**

- Wet mounts of vaginal or urethral discharge: direct visualization of motile trichomonads. Most common diagnostic method since inexpensive and available
  - Sensitivity: 60-70%; declines rapidly within 1 hour from collection
  - Specificity: 99.8%
- Culture: sensitivity: >95%, specificity >99%; takes 4 to 7 days for growth
- Nucleic acid amplification test (NAAT)
  - Gold standard for diagnosis (4)
  - Sensitivity and specificity 95-99%
  - FDA approved for vaginal, endocervical, or female urine specimens
  - Results in 1 hour
  - Limited clinical availability
- Antigen detection
  - ELISA and direct fluorescent antibody tests: sensitivity of 80-90%
  - Limited clinical availability

### *Follow-Up Tests & Special Considerations*

Detection on cervical Papanicolaou smear

- Treat since highly specific (97-99%)
- Not effective trichomonas screening test given sensitivity as low as 60%

### *Diagnostic Procedures/Other*

Detection on self-obtained sample with DNA probe assay with specificity >98%

## **TREATMENT**

- Symptomatic individuals require treatment.

- Sexual partners should be treated presumptively.
- Patients should abstain from sexual intercourse during treatment and until they are asymptomatic.

## **GENERAL MEASURES**

The nitroimidazole class is only known effective antimicrobial treatment. If metronidazole resistance is suspected, use tinidazole (5)[A].

## **MEDICATION**

### **First Line**

- Metronidazole: 2 g PO, 1 dose (6)[A]
  - FDA pregnancy risk Category B
  - Cure rate: 84-98%
- Tinidazole: 2 g PO, 1 dose (6)[A]
  - FDA pregnancy risk Category C
  - Abstain from breastfeeding during treatment and for 3 days after the dose.
  - More expensive
  - Reaches higher levels in genitourinary tract
  - Cure rate: 92-100%

### **Second Line**

- Metronidazole: 500 mg PO BID for 7 days
  - Only if still symptomatic after initial treatment
  - Considered first line in HIV-positive individuals
- Can dose with metronidazole or tinidazole 2 g daily for 7 days if infection persists
- May consider IV dosing of metronidazole based on case report that demonstrated cure after multiple failed oral regimens

### **Pregnancy Considerations**

Metronidazole is effective for trichomoniasis infection during pregnancy but may increase the risk of preterm and low-birth-weight babies.

- Studies showed risk in patients receiving four times the standard dosing.
- Trichomoniasis is also associated with prematurity.

## ***ISSUES FOR REFERRAL***

- Multidrug-resistant organism
- Patient allergy to metronidazole: Desensitization to metronidazole is recommended.

## ***ADDITIONAL THERAPIES***

- Limited clinical trials assessing effectiveness of alternative therapies (4)
- Intravaginal metronidazole gel is not effective.
- Suggested alternative therapies based on small number of case reports
  - Paromomycin 6.25% cream
  - Povidone-iodine douche
  - Boric acid intravaginally
  - Furazolidone intravaginally

---

P.1059

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

See Additional Therapies.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- If symptoms persist after initial treatment, repeat wet mount or other testing.
- Retest women for *T. vaginalis* recommended within 3 months of treatment. Data insufficient for retesting men (6)[A]
- HIV-positive patients should be screened for trichomonas at time of HIV diagnosis and at least annually (6)[A].

### ***DIET***

- Abstain from alcohol during treatment and for 24 hours following last dose of metronidazole or 48 to 72 hours following last dose of tinidazole due to disulfiram-like reaction.

## PATIENT EDUCATION

Educate about the sexually transmitted aspect.

- Advise patient to notify sexual partner to be treated.
- Discuss STI prevention—condom use can prevent recurrence.
- Abstain from intercourse while undergoing treatment; use condoms if abstention is not feasible.
- Avoid alcohol during treatment with metronidazole or tinidazole.

## PROGNOSIS

- Excellent
- Usually eliminated after one course of antibiotics

## COMPLICATIONS

### Pregnancy Considerations

Linked to low birth weight, preterm premature rupture of membranes, and preterm birth

## Codes

**&NA;**

### ICD10

- A59.9 Trichomoniasis, unspecified
- A59.03 Trichomonal cystitis and urethritis
- A59.01 Trichomonal vulvovaginitis

## Clinical Pearls

**&NA;**

- Both partners need to be treated for trichomoniasis.
- Retest women within 3 months of treatment.
- Avoid alcohol during treatment with standard agents.
- Treatment does not reduce risk of adverse pregnancy outcomes.
- Male circumcision may be protective.
- Annual screening recommended for HIV-positive patients.

Not a nationally notifiable condition

# Trichotillomania

Carol Hustedde, PhD

William G. Elder, PhD

## BASICS

- Trichotillomania (TTM) is a hair-pulling disorder characterized by self-induced, repeated, and often noticeable hair loss. It can become severe and difficult to control.
- TTM is currently conceptualized as a compulsive behavior related to obsessive-compulsive disorder (OCD). Tension or boredom typically play a significant role, and the individual may be conscious or unconscious that they are pulling hair.

## DESCRIPTION

- TTM causes uncontrollable hair pulling from anywhere on the body, although the scalp is the most common area followed by the eyelashes, eyebrows, pubic/perirectal area, axilla, and face. It usually results in variable degrees of alopecia.
- TTM usually presents in childhood or early adolescence.
- Denial and hiding of hair pulling is common.
- Recurrence or worsened hair pulling is associated with increased stress/anxiety, but TTM can also occur at times of relaxation and distraction, such as when reading.
- The three subtypes of TTM: early onset, automatic, and focused
- When TTM is associated with trichophagia, it may also result in GI complaints secondary to bezoars
- TTM has frequent comorbidity with other psychiatric diagnoses

## EPIDEMIOLOGY

- It is difficult to assess the exact number of individuals affected by TTM because of the social stigma associated with it. Small studies have estimated a range of 1-3.5% for late adolescents and young adults.
- It is possible that up to 1 of 50 individuals are affected by TTM at least once in their lifetime.
- The mean age of onset is at 13 years.

- During childhood, males and females are equally affected by TTM. During adulthood, females are far more affected than males.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Serotonin deficiency
- Tension relief
- Habitual behavior
- There is currently a significant flux in the conceptualizations of the mechanisms and causes of impulse control, behavior, anxiety, and OCDs. Brain imaging and biochemical and neuropsychological studies should help to resolve this issue. It can be expected that there will be increased differentiation as well as redefinitions of disorders that are based on neurophysiology and brain circuitry.

### *Genetics*

Genetics appears to contribute to the development of TTM as demonstrated by a higher rate of concordance in monozygotic twins (38.1%) versus dizygotic twins (0%). Genetic involvement is multifaceted and not clearly understood at this time.

## *RISK FACTORS*

- Positive family history
- Other psychiatric disorders: depression, OCD, anxiety, posttraumatic stress disorder (PTSD), eating disorders, nail biting, skin picking

## *COMMONLY ASSOCIATED CONDITIONS*

- Depression
- Anxiety
- OCD
- Eating disorders

## **DIAGNOSIS**

- TTM may be difficult to diagnose because individuals may deny it because of the social stigma and embarrassment.
- Several TTM-specific assessment tools have been developed that further understands about

psychopathology of TTM.

- Assessment should include multiple sources of information to provide understanding of TTM in context.

## **HISTORY**

- TTM most commonly manifests as hair pulling from any part of the body, resulting in alopecia of variable severity.
- The scalp is the most common area from which hair is pulled but can also involve other parts of the body, such as eyebrows and eyelashes.
- Individuals will conceal hair pulling because of embarrassment. However, when asked about it by a medical professional, they will divulge extent of problem and their efforts to control it.
- TTM may also cause social isolation because individuals may withdraw from friends and family to engage in hair-pulling behavior.
- If TTM is associated with trichophagia (compulsive eating of hair), it may present with various GI symptoms with variable severity, from acute generalized abdominal pain to a bowel obstruction secondary to a trichobezoar.
- TTM is not always associated with anxiety and stress, but it is commonly precipitated by highly stressful situations. The action of hair pulling may be associated with tension relief.

## **PHYSICAL EXAM**

- The most common manifestation of TTM is alopecia.
- The severity of the alopecia is variable, from isolated areas of hair loss to complete baldness.
- Hair loss can be from any part of the body.
- The Friar Tuck sign may be seen, which consists of hair loss seen in a circular pattern with varying lengths of broken hairs.
- There is also a lack of dermatologic abnormalities associated with the hair loss.
- In addition to the hair loss, hair abnormalities consisting of damaged hair follicles, broken hairs of varying lengths
- When TTM is associated with trichophagia and, consequently, trichobezoars, there may be symptoms of abdominal pain, nausea, vomiting, obstructive jaundice, bowel obstruction symptoms, and anemia.
- Patients with TTM may also pull hairs from other people and pets, sometimes surreptitiously.

They may also pull fibers from carpets and fabrics.

## *DIFFERENTIAL DIAGNOSIS*

- Alopecia areata
- Tinea capitis
- Traction alopecia
- Loose anagen syndrome
- OCD
- Schizophrenia or other psychotic disorders
- Stereotypic movement disorders
- Factitious behaviors

## *DIAGNOSTIC TESTS & INTERPRETATION*

US or CT scan for trichobezoar detection

### *Diagnostic Procedures/Other*

- Trichotillomania Scale for Children
- Trichotillomania Diagnostic Interview
- National Institute of Mental Health Trichotillomania Questionnaire
- Premonitory Urge for Tics Scale

---

P.1061

## **Test Interpretation**

- Punch biopsy: high frequency of telogen hairs; deformed, noninflamed catagen hairs; melanin pigment casts
- Trichogram
- Referrals
  - Some diagnostic procedures may require a dermatology referral. In the presence of missing hair follicles or other hair disorder, a dermatology consult will allow for visual and/or microscopic (trichogram) analysis to determine structure and cycle of the hair disorder.
  - A referral to a psychiatrist, psychologist, or psychopharmacologist who specializes in impulse control and OCD may be helpful. He or she will have access to the specialized

symptoms scales described above and also is likely to have professional relationships with psychotherapists who can provide specific therapies, such as habit reversal training. Such referral may also allow for stepped treatment including aggressive use of SSRIs and other antidepressants with combinations of second-line pharmacologic options sometimes tried for impulse control and OCD disorders.

## TREATMENT

- Treatment of TTM involves both psychological methods that include specific psychotherapies, pharmacologic treatment, and combined approaches.
- Psychological treatment of TTM may be the primary treatment and is almost always needed in addition to medications.
  - Habit reversal training (HRT) has the strongest empirical support in adults (1)[B]:
    - HRT is a behavioral therapy that is effective in reducing troublesome behaviors associated with TTM. It consists of four main components: awareness training, development of a competing response, building motivation, and generalization of skills.
  - Principles of cognitive-behavior therapy (CBT) can be adjusted to developmental age to treat young children (2)[B].
  - Relaxation training (when stress is high)
  - Support groups to deal with stigma and denial
  - Treatment of comorbid psychiatric condition
  - Unlikely to be helpful
    - Undifferentiated, nonspecific psychotherapy
    - Hypnosis
    - Acupuncture
  - A nutritional supplement, N-acetylcysteine (1,200 to 2,400 mg/day), shows some benefit for adults but not for children and adolescents.

## MEDICATION

- Previous RCT studies evaluate pharmacotherapy across various classes of medications had small sample sizes and did not indicate benefit (3).
- SSRIs have not demonstrated efficacy and most studies reported findings on subjects with little comorbidity. These medications may be options in concert with CBT.

- Fluoxetine (Prozac): 20 to 80 mg/day
  - Sertraline (Zoloft): 50 to 200 mg/day
  - Paroxetine (Paxil): 10 to 50 mg/day
  - Citalopram (Celexa): 20 to 40 mg/day
  - Escitalopram (Lexapro): 10 to 20 mg/day
- Glutamate modulators (e.g., N-acetylcysteine) may reduce TTM in adults; however, benefit has not been demonstrated for children (4).

## ***SURGERY/OTHER PROCEDURES***

Surgery is only warranted for removal of trichobezoars.

## ***INPATIENT CONSIDERATIONS***

Inpatient admission is usually not due to TTM itself but either treatment of comorbid psychiatric conditions or a bowel obstruction secondary to trichobezoar.

## **ONGOING CARE**

### ***DIET***

No special diet required for TTM

### ***PATIENT EDUCATION***

- TTM is a multifactorial condition. Not only do medications aid in the treatment of TTM, but also psychological therapies may have a significant benefit as well.
- Online resources: [www.trich.org](http://www.trich.org); [www.stoppulling.com](http://www.stoppulling.com)

### ***PROGNOSIS***

TTM tends to be a chronic disorder; however, it can be transient in childhood.

### **COMPLICATIONS**

- Trichobezoars
- Alopecia

## Codes

&NA;

ICD10

F63.3 Trichotillomania

## Clinical Pearls

## **&NA;**

- Etiology of TTM is multifactorial and differs among individuals. It is important to distinguish between different etiologies.
- TTM may occur in the presence of comorbid conditions.
- Patients may benefit from psychotherapy and selected medications.
- It is important to realize that TTM is underreported and underdiagnosed because of the social stigma.
- TTM can have a significant impact on psychological, social, academic, and occupational functions.

# Trigeminal Neuralgia

Noah M. Rosenberg, MD

## BASICS

### DESCRIPTION

- Disorder of the sensory nucleus of the trigeminal nerve (cranial nerve [CN] V) that produces episodic, paroxysmal, severe, lancinating facial pain lasting seconds to minutes in the distribution of >1 divisions of the nerve
- Often precipitated by stimulation of well-defined, ipsilateral trigger zones: usually perioral, perinasal, and, occasionally, intraoral (e.g., by washing, shaving)
- System(s) affected: nervous
- Synonym(s): tic douloureux; Fothergill neuralgia; trifacial neuralgia; prosopalgia

### EPIDEMIOLOGY

#### Incidence

- Women: 5.9/100,000/year
- Men: 3.4/100,000/year
- >70 years of age: ÷ 25.6/100,000/year
- Predominant age:
  - >50 years; incidence increases with age
  - Rare: <35 years of age (consider another primary disease; see ÒEtiologyÓ)
- Predominant sex: female > male (÷2:1)

#### Prevalence

16/100,000

#### Pediatric Considerations

Unusual during childhood

## *Pregnancy Considerations*

Teratogenicity limits therapy for 1st and 2nd trimesters.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Demyelination around the compression site seems to be the mechanism by which compression of nerves leads to symptoms.
- Demyelinated lesions may set up an ectopic impulse generation causing erratic responses: hyperexcitability of damaged nerves and transmission of action potentials along adjacent, undamaged, unstimulated sensory fibers
- Compression of trigeminal nerve by anomalous arteries or veins of posterior fossa, compressing trigeminal root
- Etiologic classification:
  - Idiopathic (classic)
  - Secondary: cerebellopontine angle tumors (e.g., meningioma); tumors of CN V (e.g., neuroma, vascular malformations), trauma, demyelinating disease (e.g., multiple sclerosis [MS])

## **RISK FACTORS**

Unknown

## **COMMONLY ASSOCIATED CONDITIONS**

- Sjögren syndrome; rheumatoid arthritis
- Chronic meningitis
- Acute polyneuropathy
- MS
- Hemifacial spasm
- Charcot-Marie-Tooth neuropathy
- Glossopharyngeal neuralgia

## **DIAGNOSIS**

### **HISTORY**

Paroxysms of pain in the distribution of the trigeminal nerve

## *PHYSICAL EXAM*

All exam findings typically are negative due to the paroxysmal nature of the disorder.

## *DIFFERENTIAL DIAGNOSIS*

- Other forms of neuralgia usually have sensory loss. Presence of sensory loss nearly excludes the diagnosis of TN (if younger patient, frequently MS).
- Neoplasia in cerebellopontine angle
- Vascular malformation of brain stem
- Demyelinating lesion (MS is diagnosed in 2-4% of patients with trigeminal neuralgia.)
- Vascular insult
- Migraine, cluster headache
- Giant cell arteritis
- Postherpetic neuralgia
- Chronic meningitis
- Acute polyneuropathy
- Atypical odontalgia
- SUNCT syndrome (short-lasting, unilateral, neuralgiform pain with conjunctival injection, and tearing)

## *DIAGNOSTIC TESTS & INTERPRETATION*

- The International Headache Society diagnostic criteria for classic trigeminal neuralgia (TN) are as follows:
  - Paroxysmal attacks of pain lasting from a fraction of 1 second to 2 minutes, affecting <sup>3</sup> 1 divisions of the trigeminal nerve
  - Pain has at least an intense, sharp, superficial, or stabbing characteristic; or is precipitated from trigger areas or by trigger factors.
  - Attacks are stereotyped in the individual patient.
  - No clinically evident neurologic deficit found.
  - Not attributed to another disorder
- Secondary TN is characterized by pain that is indistinguishable from classic TN but is caused by a demonstrable structural lesion other than vascular compression.

- Indicated in all first-time-presenting patients to rule out secondary causes
- MRI versus CT scan: MRI, with and without contrast, offers more detailed imaging and is preferred, if not contraindicated.
- Routine head imaging identifies structural causes in up to 15% of patients.
- No positive findings are significantly correlated with diagnosis.

## *Test Interpretation*

- Trigeminal nerve: inflammatory changes, demyelination, and degenerative changes
- Trigeminal ganglion: hypermyelination and microneuromata

## **TREATMENT**

### *GENERAL MEASURES*

- Outpatient
- Drug treatment is first approach.
- Invasive procedures are reserved for patients who cannot tolerate, fail to respond to, or relapse after chronic drug treatment.
- Avoid stimulation (e.g., air, heat, cold) of trigger zones, including lips, cheeks, and gums.

### *MEDICATION*

#### **First Line**

- Carbamazepine (Tegretol) (1)[A]: Start at 100 to 200 mg BID; effective dose usually 200 mg QID; max dose 1,200 mg/day:
  - 70-90% of patients respond initially.
  - By 3 years, 30% are no longer helped (number needed to treat [NNT] = 1.7) (1)[A]
  - Most common side effect: sedation
- Contraindications: concurrent use of monoamine oxidase inhibitors (MAOIs)
- Precautions: caution in the presence of liver disease
- Significant possible medication interactions: macrolide antibiotics, oral anticoagulants, anticonvulsants, tricyclics, oral contraceptives, steroids, digitalis, isoniazid, MAOIs,

methyprylon, nabilone, nizatidine, other H<sub>2</sub> blockers, phenytoin, propoxyphene, benzodiazepines, and calcium channel blockers

- Oxcarbazepine (Trileptal): Start at 150 to 300 mg BID; effective dose usually 375 mg BID; max dose 1,200 mg/day:
  - Efficacy similar to carbamazepine
  - Faster, with less drowsiness and fewer drug interactions than carbamazepine
  - May cause hyponatremia
  - Most common side effect: sedation

## *Second Line*

- Antiepileptic drugs: Insufficient evidence from randomized, controlled trials to show significant benefit from antiepileptic drugs in TN (2)[A].
- Phenytoin (Dilantin): 300 to 400 mg/day (synergistic with carbamazepine):
  - Potent P450 inducer (enhanced metabolism of many drugs)
  - Various CNS side effects (sedation, ataxia)
- Baclofen (Lioresal): 10 to 80 mg/day; start at 5 to 10 mg TID with food (as an adjunct to phenytoin or carbamazepine); side effects: drowsiness, weakness, nausea, vomiting
- Gabapentin (Neurontin): Start at 100 mg TID or 300 mg at bedtime; can increase dose up to 300 to 600 mg TID-QID. Can be used as monotherapy or in combination with other medications and reduces the cost of illness.
- Lamotrigine: Titrate up to 200 mg BID over weeks; side effect: 10% experience rash

---

P.1063

- Antidepressants, including amitriptyline, fluoxetine, trazodone:
  - Used especially with anticonvulsants
  - Particularly effective for atypical forms of TN
- Clonazepam (Klonopin) frequently causes drowsiness and ataxia.
- Sumatriptan (Imitrex) 3 mg SC reduces acute symptoms and may be helpful after failure of conventional medical therapy.
- Capsaicin cream topically
- Botulinum toxin injection into zygomatic arch
- Valproic acid (Depakene, Depakote)

## *ISSUES FOR REFERRAL*

Initial treatment failure or positive findings on imaging studies

## *ADDITIONAL THERAPIES*

- Radiotherapy
- Stereotactic radiosurgery, such as gamma knife radiosurgery, has been shown to be effective after drug failure:
  - Produces lesions with focused gamma knife radiation
  - Therapy aimed at the proximal trigeminal root
  - Minimal clinically effective dose: 70 Gy
  - ÷ 60-80% of patients achieve complete relief within 1 year; by 3 years, ÷ 30-40% maintain complete relief (3)[B].
  - Most common side effect: sensory disturbance (facial numbness)
  - Failure rates are higher in patients with past TN-related invasive procedures.

## *SURGERY/OTHER PROCEDURES*

- Microvascular decompression of CN V at its entrance to (or exit from) brain stem:
  - 98% of patients achieve initial pain relief; by 20 months, 86% maintain complete relief (NNT = 2) (4)[B].
  - Surgical mortality across studies was 0.3-0.4%.
  - Most common side effect: transient facial numbness and diplopia, headache, nausea, vomiting
  - Pain relief after procedure strongly correlates with the type of TN pain: Type 1 (shocklike pain) results in better outcomes than type 2 (aching pain between paroxysms).
- Peripheral nerve ablation (multiple methods):
  - Higher rates of failure and facial numbness than decompression surgery
  - Radiofrequency thermocoagulation
  - Neurectomy
  - Cryotherapy: high relapse rate
  - Partial sensory rhizotomy

- 4% tetracaine dissolved in 0.5% bupivacaine nerve block (only a few case reports to date; ropivacaine)
- Alcohol block or glycerol injection into trigeminal cistern: unpredictable side effects (dysesthesia and anesthesia dolorosa); temporary relief
- Peripheral block or section of CN V proximal to Gasserian ganglion
- Balloon compression of Gasserian ganglion
- Evidence supporting destructive procedures for benign pain conditions remains limited (5)[A].

## COMPLEMENTARY & ALTERNATIVE MEDICINE

Acupuncture, moxibustion (herb): weak evidence for efficacy (6)[B]

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

Regular outpatient follow-up to monitor symptoms and therapeutic failure.

#### *Patient Monitoring*

- Carbamazepine and/or phenytoin serum levels
- If carbamazepine is prescribed: CBC and platelets at baseline, then weekly for a month, then monthly for 4 months, then every 6 to 12 months if dose is stable (regimens for monitoring vary)
- Reduce drugs after 4 to 6 weeks to determine whether condition is in remission; resume at previous dose if pain recurs. Withdraw drugs slowly after several months, again to check for remission or if lower dose of drugs can be tolerated.

### DIET

No special diet

### PATIENT EDUCATION

- Instruct patient regarding medication dosage and side effects, risk-to-benefit ratios of surgery, or radiation therapy.
- Support organizations:
  - The Facial Pain Association (formerly the Trigeminal Neuralgia Association): [www.fpa-support.org](http://www.fpa-support.org)

- Living with Trigeminal Neuralgia: [www.livingwithtn.org](http://www.livingwithtn.org)

## PROGNOSIS

- 50-60% eventually fail pharmacologic treatment.
- After having microvascular decompression surgery, most patients wish they had undergone the procedure sooner.
- Of those, relapse is seen in ÷ 50% of stereotactic radiosurgeries and ÷ 27% of surgical microvascular decompressions.

## COMPLICATIONS

- Mental and physical sluggishness; dizziness with carbamazepine
- Paresthesias and corneal reflex loss with stereotactic radiosurgery
- Surgical mortality and morbidity associated with microvascular decompression

Practice parameter: the diagnostic evaluation and treatment of trigeminal neuralgia (an evidence-based review): report of the Quality Standards Subcommittee of the American Academy of Neurology and the European Federation of Neurological Societies. *Neurology*. 2008;71(15):1183-1190.

## Codes

**&NA;**

### ICD10

- G50.0 Trigeminal neuralgia
- B02.22 Postherpetic trigeminal neuralgia

## Clinical Pearls

**&NA;**

- Patients with TN typically have a normal physical exam.
- The long-term efficacy of pharmacotherapy for TN is 40-50%.
- If pharmacotherapy fails, stereotactic radiosurgery or surgical microvascular decompression often is successful.

# Trigger Finger (Digital Stenosing Tenosynovitis)

Alan M. Ehrlich, MD

Robert A. Yood, MD

## BASICS

### *DESCRIPTION*

A clicking, snapping, or locking of a finger/thumb with extension movement (after flexion) ± associated pain

### *EPIDEMIOLOGY*

#### **Incidence**

- Adult population: 28/100,000/year
  - Rare in children
- 4 times increased risk in diabetics (1)[B].
- Predominant age
  - Childhood form typically involves thumb.
  - Adult form typically presents in the 5th and 6th decades of life and involves thumb/digits.
- Predominant sex
  - Children: female = male
  - Adults: female > male (6:1)

#### *Prevalence*

Lifetime prevalence in the general population is 2.6%.

#### *Pediatric Considerations*

- The thumb is more commonly involved in children.
- Surgery is often more complicated for children with a trigger finger (as opposed to a trigger

thumb).

- Release of the A1 pulley alone is often insufficient, other procedures may be necessary.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Narrowing around the A1 pulley from inflammation, protein deposition, or thickening of the tendon itself. Prolonged inflammation leads to fibrocartilaginous metaplasia of the tendon sheath.
- If the flexor tendon become nodular, the triggering phenomenon is worse because the nodule has difficulty passing under the A1 pulley.
- Because intrinsic flexor muscles are stronger than extensors, the finger can stick in the flexed position.
- No clear association with repetitive movements

## *RISK FACTORS*

- Diabetes mellitus
- Rheumatoid arthritis
- Hypothyroidism
- Mucopolysaccharide disorders
- Amyloidosis

## *GENERAL PREVENTION*

Most cases are idiopathic, and no known prevention exists. No clear association with repetitive movements

## *COMMONLY ASSOCIATED CONDITIONS*

- De Quervain tenosynovitis
- Carpal tunnel syndrome
- Dupuytren contracture
- Diabetes mellitus
- Rheumatoid arthritis
- Hypothyroidism
- Amyloidosis

## DIAGNOSIS

Diagnosis is based on clinical presentation.

### HISTORY

Clicking, snapping, or locking of a digit while attempting to extend; with or without associated pain

### PHYSICAL EXAM

- A palpable nodule may be present.
- Snapping/locking may be present but neither is necessary for the diagnosis.
- Tenderness to palpation is variable.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Test Interpretation

- Thickening of the A1 pulley with fibrocartilaginous metaplasia
- Thickening/nodule formation of flexor tendon

## TREATMENT

- Splinting the metacarpophalangeal (MCP) joint at 10 to 15 degrees of flexion for 6 weeks with the distal joints free to move:
  - Splinting is more effective for fingers than thumbs (70% vs. 50%).
  - Splinting is less effective with severe symptoms, symptoms >6 months, or if multiple digits are involved (1)[B].
- Injection of long-acting corticosteroid may provide symptom relief. Subsequent injections are less likely to help.
- Surgery often successful for patients unresponsive to splinting/corticosteroid injections.

### GENERAL MEASURES

Attempt splinting/steroid injection prior to surgery. Splinting may be more effective for preventing recurrence than as initial treatment (2)[B].

# MEDICATION

## First Line

- Steroid injection of the tendon sheath/surrounding SC tissue has 57-90% success rate.
- Injection in surrounding tissues is as efficacious as injecting into the tendon sheath (1,3)[B]. Injection into the palmar surface at the midproximal phalanx is associated with less pain than injection of tendon sheath at MCP joint (4)[B].
- Injection using ultrasound guidance does not improve success rate compared to standard injection technique (5)[A]. Corticosteroid injection has higher success rate than splinting (2)[B].

## Second Line

- Oral NSAIDs may reduce pain and discomfort but have not been shown to alter underlying disease. NSAIDs do not reduce symptoms of snapping/locking.

---

P.1065

- Injection with diclofenac may be an alternative to corticosteroid for patients with diabetes mellitus if increase in blood sugar is a concern (6)[A].
- Corticosteroids are more effective than diclofenac during the first 3 weeks postinjection. Efficacy is similar to other modalities by 3 months postinjection (6)[B].
- In one randomized trial, hyaluronic acid (HA) injections were as effective as corticosteroid injections. The optimal frequency, dosage, and molecular weight of HA injections has yet to be adequately studied.

## ISSUES FOR REFERRAL

Refer to a hand surgeon for release if the patient is not responding to splinting and/or steroid injections.

## ADDITIONAL THERAPIES

Physiotherapy is helpful, particularly in children.

## SURGERY/OTHER PROCEDURES

- Surgical release can be done as an open procedure or percutaneously.
- No apparent differences in success or rates of complications between surgical approaches (6)[A].
- Surgery has a lower rate of recurrence than corticosteroid injection (6)[A].

- Most hand surgeons prefer open release because of concern about nerve injury.

## INPATIENT CONSIDERATIONS

### Admission Criteria/Initial Stabilization

Day surgery for trigger finger release

### Discharge Criteria

Absence of complications

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

- Follow up is needed only if symptoms persist or if complications develop after surgery.
- Splinting of the affected digit to minimize flexion/extension of the MCP joint helps symptom resolution (1)[B],(7)[C].

### PROGNOSIS

Prognosis is excellent with conservative treatment or surgical intervention. Recurrence following corticosteroid injection is more likely for patients with type 1 diabetes mellitus, younger patients, involvement of multiple digits, and patients with a history of other upper extremity tendinopathies (8)[B].

### COMPLICATIONS

- Complications from surgery include infection, bleeding, digital nerve injury, persistent pain, and loss of range of motion of the affected finger. The rate of major complications is low (3%). The rate of minor complications (including loss of range of motion) is higher (up to 28%).
- Injury to the A2 pulley may result in bowstringing, (bulging of the flexor tendon in the palm with flexion). This can be painful.
- Diabetic patients may have increased blood sugar levels for up to 5 days following steroid injection.

## Codes

**&NA;**

### ICD10

- M65.30 Trigger finger, unspecified finger
- M65.319 Trigger thumb, unspecified thumb
- M65.329 Trigger finger, unspecified index finger

## Clinical Pearls

**&NA;**

- Trigger finger is caused by narrowing of the A1 flexor tendon pulley.
- Splinting the MCP joint at 10 to 15 degrees flexion for 6 weeks is the preferred initial conservative treatment.
- Splinting is more effective for fingers as opposed to thumbs (70% vs. 50%). Splinting is less effective with severe symptoms, longstanding symptoms (>6 months), or if multiple digits are involved.
- Long-acting corticosteroid injections are effective for treatment of trigger finger.
- Open and percutaneous surgical release has high success rates for patients not responsive to splinting or injections.

# Trochanteric Bursitis (Greater Trochanteric Pain Syndrome)

David W. Kruse, MD

Joann Y. Chang, MD

## BASICS

*Trochanteric bursitis* is the historical term referring to lateral hip pain and tenderness over the greater trochanter. Because many patients lack an inflammatory process within the trochanteric bursa, this condition has been more recently referred to as *greater trochanteric pain syndrome* (GTPS) (1).

## DESCRIPTION

- Bursae are fluid-filled sacs found primarily at tendon attachment sites with bony protuberances:
  - Multiple bursae are in the area of the greater trochanter of the femur.
  - These bursae are associated with the tendons of the gluteus muscles, iliotibial band (ITB), and tensor fasciae latae.
  - The subgluteus maximus bursa is implicated most commonly in lateral hip pain (1).
- Other structures of the lateral hip include the following:
  - ITB, tensor fasciae latae, gluteus maximus tendon, gluteus medius tendon, gluteus minimus tendon, quadratus femoris muscle, vastus lateralis tendon, piriformis tendon
- *Bursitis* refers to bursal inflammation.
- *Tendinopathy* refers to any abnormality of a tendon, inflammatory or degenerative. *Enthesopathy* refers to abnormalities of the zones of attachment of ligaments and tendons to bones.

## EPIDEMIOLOGY

### Incidence

- 1.8/1,000 persons/year

Peak incidence in 4th to 6th decades

## *Prevalence*

- Predominant sex: female > male
- More common in running and contact athletes
  - Football, rugby, soccer

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Acute: abnormal gait or poor muscle flexibility and strength imbalances lead to bursal friction and secondary inflammation
  - Tendon overuse and inflammation
  - Direct trauma from contact or frequently lying with body weight on hip can cause an inflammatory response (Òhip pointerÓ) as well.
- Chronic
  - Fibrosis and thickening of bursal sac due to chronic inflammatory process
  - Tendinopathy due to chronic overuse and degeneration: gluteus medius and minimus most commonly involved (1,2)

## *Genetics*

No known genetic factors

## *RISK FACTORS*

Multiple factors have been implicated (1,3):

- Female gender
- Obesity
- Tight hip musculature (including ITB)
- Direct trauma
- Total hip arthroplasty
- Abnormal gait or pelvic architecture
  - Leg length discrepancy
  - Sacroiliac (SI) joint dysfunction

- Knee or hip osteoarthritis
- Abnormal foot mechanics (e.g., pes planus, overpronation)
- Neuromuscular disorder: Trendelenburg gait

## GENERAL PREVENTION

- Maintain ITB, hip, and lower back flexibility and strength.
- Avoid direct trauma (use of appropriate padding in contact sports).
- Avoid prolonged running on banked or crowned surfaces.
- Wear appropriate shoes.
- Appropriate bedding and sleeping surface
- Maintain appropriate body weight loss.

## COMMONLY ASSOCIATED CONDITIONS

- Biomechanical factors (1)
  - Tight ITBs, leg length discrepancy, SI joint dysfunction, pes planus
  - Width of greater trochanters greater than width of iliac wings (4)[B]
- Other associated pathology (1):
  - Low back pain
  - Knee and hip osteoarthritis
  - Obesity

## DIAGNOSIS

### HISTORY

#### General history (1)

- Pain localized to the lateral hip or buttock
- Pain may radiate to groin or lateral thigh (pseudoradiculopathy).
- Pain exacerbated by:
  - Prolonged walking or standing
  - Rising after prolonged sitting
  - Sitting with legs crossed

- Lying on affected side
- Other historical features:
  - Direct trauma to affected hip
  - Chronic low back pain
  - Chronic leg/knee/ankle/hip pain
  - Recent increase in running distance or intensity
  - Change in running surfaces

## *PHYSICAL EXAM*

- Observe gait.
- Point tenderness with direct palpation over the lateral hip is characteristic of GTPS (1)[B].
- Other exam features have lower sensitivity (1)[B]:
  - Pain with extremes of passive rotation, abduction, or adduction
  - Pain with resisted hip abduction and external or internal rotation
  - Trendelenburg sign
- Other tests to rule out associated conditions:
  - Patrick-FABERE (flexion, abduction, external rotation, extension) test for SI joint dysfunction
  - Ober test for ITB pathology
  - Flexion and extension of hip for osteoarthritis
  - Leg length measurement
  - Foot inspection for pes planus or overpronation
  - Lower extremity neurologic assessment for lumbar radiculopathy or neuromuscular disorders
  - Hip lag sign (5)

## *DIFFERENTIAL DIAGNOSIS*

- ITB syndrome
- Piriformis syndrome
- Osteoarthritis or avascular necrosis of the hip
- Lumbosacral osteoarthritis/disc disease with nerve root compression

- Fracture or contusion of the hip or pelvis—particularly in setting of trauma
- Stress reaction/fracture of femoral neck—particularly in female runners
- Septic bursitis/arthritis

## ***DIAGNOSTIC TESTS & INTERPRETATION***

No routine lab testing is recommended.

### ***Initial Tests (lab, imaging)***

- Diagnosis can be made by history and exam (6).
- If imaging is ordered:
  - US can aid in diagnosis and guide aspiration and/or injection.
  - Anteroposterior and frog-leg views of affected hip to rule out specific bony pathology (OA, stress fracture, etc).
  - Consider lumbar spine radiographs if back pain is thought to be a contributing factor.
  - MRI is image of choice in recalcitrant pain or to formally exclude stress fracture.

### ***Follow-Up Tests & Special Considerations***

- If there is a concern for a septic bursitis, then aspiration or incision and drainage may be necessary.
- Advanced imaging rarely necessary; detection of abnormalities on MRI is a poor predictor of GTPS (7)[B].

---

P.1067

## **TREATMENT**

### ***GENERAL MEASURES***

- Physical therapy to address underlying dysfunction and rebuild atrophic muscle
- Correct pelvic/hip instability.
- Correct lower limb biomechanics.
- Low-impact conditioning and aquatic therapy
- Gait training

- Weight loss (if applicable)
- Minimize aggravating activities such as prolonged walking or standing.
- Avoid lying on affected side.
- Runners
  - May need to decrease distance and/or intensity of runs during treatment. Some need to stop running. Amount of time is case specific but may range from 2 to 4 weeks.
  - Avoid banked tracks or roads with excessive tilt.

## *MEDICATION*

### **First Line**

- NSAIDs (1)[B]: Treat for 2 to 4 weeks.
  - Naproxen: 500 mg PO BID
  - Ibuprofen: 800 mg PO TID
- Corticosteroid injection is effective for pain relief (8)[C] and can be considered first-line therapy for selected cases:
  - Dexamethasone: 4 mg/mL or
  - Kenalog: 40 mg/mL, use 1 to 2 mL
  - Consider adding a local anesthetic (short- and/or long-acting) for more immediate pain relief.
  - Can be repeated with similar effect if original treatment showed a strong response
  - Goal is pain relief (9)[A].

## *ISSUES FOR REFERRAL*

- Septic bursitis
- Recalcitrant bursitis

## *ADDITIONAL THERAPIES*

- Ice
- Low-energy shock wave therapy has been shown to be superior to other nonoperative modalities (8)[A].

Focus on achieving flexibility of hip musculature, particularly the ITB.

- Address contributing factors:
  - Low back flexibility
  - If leg length discrepancy, consider heel lift.
  - If pes planus or overpronation, consider arch supports or custom orthotics.

## ***SURGERY/OTHER PROCEDURES***

- Surgery rare but effective in refractory cases (10)[A]
- If surgery is indicated, potential options include:
  - Arthroscopic bursectomy
  - ITB release
  - Gluteus medius tendon repair

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Acupuncture
- Prolotherapy
- Growth factor injection techniques
- Platelet-rich plasma injection

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

4 weeks posttreatment, sooner if significant worsening

### ***PATIENT EDUCATION***

- Maintain hip musculature flexibility, including ITB.
- Correct issues that may cause abnormal gait:
  - Low back pain
  - Knee pain
  - Leg length discrepancy (heel lift)

- Foot mechanics (orthotics)
- Gradual return to physical activity

## PROGNOSIS

Depends on chronicity and recurrence, with more acute cases having an excellent prognosis

## COMPLICATIONS

Bursal thickening and fibrosis

## Codes

**&NA;**

### ICD10

- M70.60 Trochanteric bursitis, unspecified hip
- M70.62 Trochanteric bursitis, left hip
- M70.61 Trochanteric bursitis, right hip

## Clinical Pearls

**&NA;**

- Patients with GTPS often present with an inability to lie on the affected side.

Femoral neck stress fractures are a do-not-miss diagnosis, particularly in young female runners.

- Corticosteroid injection helps as an initial therapy, particularly for pain relief to allow for aggressive physical therapy.
- Physical therapy is treatment mainstay for correcting biomechanical imbalances and restoring proper function.

# Tuberculosis

Carlos Atore, MD

Swati Avashia, MD, FAAP

## BASICS

### DESCRIPTION

- Active tuberculosis
  - Occurs from primary infection or reactivation of latent infection
  - Affects 10% of infected individuals without preventive therapy
  - Risk increases with immunosuppression: Highest risk is in the first 2 years after infection.
  - Well-described forms: pulmonary (85% of cases), miliary (disseminated), meningeal, abdominal
- Usually acquired by inhalation of airborne bacilli from an individual with active tuberculosis (TB). Bacilli multiply in alveoli and spread via macrophages, lymphatics, and blood. Three possible outcomes:
  - Eradication: Tissue hypersensitivity halts infection within 10 weeks.
  - Primary infection
  - Latent infection (See *Tuberculosis, Latent [LTBI]*.)

### *Pediatric Considerations*

- In children, there is a faster rate of progression to disease, the risk of progression to disease is higher, and severe disease is more common.
- Most children with pulmonary TB are asymptomatic.
- Treatment of pediatric TB should involve four drugs and be directly observed (DOT).

### EPIDEMIOLOGY

#### Incidence

- Worldwide (2013): 9 million (13% HIV coinfecting)

- United States (2013): 9,582 (3.0/100,000), 82 MDR, and 75 of those were foreign born (1).

## Prevalence

- Worldwide (2013): 157 cases/100,000 population (41% decrease since 1990); highest in Asia and Africa (1)

## ETIOLOGY AND PATHOPHYSIOLOGY

- *Mycobacterium tuberculosis*, *Mycobacterium bovis*, or *Mycobacterium africanum* are causative organisms.
- Cell-mediated response by activated T lymphocytes and macrophages forms a granuloma that limits bacillary replication. Destruction of the macrophages produces early caseous necrosis. In 2 to 3 weeks, caseous necrosis develops and latent tuberculosis infection (LTBI) ensues. In immunocompetent, granuloma undergoes fibrosis and calcification. In immunocompromised patients, primary progressive TB develops.

## RISK FACTORS

- For infection: homeless, ethnic minorities, close quarters (correctional facilities, nursing homes, barracks); close contact with infected individual; persons from areas with high incidence of active TB (Asia, Africa, Latin America, former Soviet Union states); health care workers; medically underserved, low income, substance abuse
- For development of disease once infected: HIV; lymphoma; silicosis; diabetes mellitus; chronic renal failure; cancer of head, neck, or lung; children <5 years of age; malnutrition; systemic corticosteroids, immunosuppressive drugs; IV drug abuse, alcohol abuse, cigarette smokers; <2 years since infection with *M. tuberculosis*; history of gastrectomy or jejunal bypass; <90% of ideal body weight

## GENERAL PREVENTION

- Screening and treatment of LTBI. Active cases must be reported to health department for identification; test and treat all close contacts.
- Bacille Calmette-Guérin (BCG) vaccine: Live attenuated *M. bovis* prevents 50% of pulmonary disease and 80% of meningitis and miliary disease in children. Use is more common in countries with endemic TB. In the United States, consider BCG for high-risk children with negative PPD and HIV tests or for health workers at risk for drug-resistant infection.

## COMMONLY ASSOCIATED CONDITIONS

Immunosuppression; HIV-coinfection; malignancy

## DIAGNOSIS

### HISTORY

- Known exposure to individual with active TB
- Immunosuppression
- Tobacco use; recreational drug use
- Signs and symptoms
  - General: fever, night sweats, weight loss, malaise, painless lymph node swelling
  - Pulmonary TB: cough, hemoptysis
  - Abdominal TB: presents acutely as surgical abdomen; chronic abdominal TB varies in presentation, vague abdominal symptoms, abdominal mass, "doughy" abdomen.
  - Meningitis: See "Tuberculosis, CNS."
  - Miliary: See "Tuberculosis, Miliary."

### PHYSICAL EXAM

- Often entirely normal. Specific findings depend on organs involved: adenopathy, rales, or hepatosplenomegaly.
- Late findings: renal, bone, or CNS disease

### DIFFERENTIAL DIAGNOSIS

- Pulmonary TB: pneumonia (bacterial fungal, atypical), malignancy, tularemia, actinomycosis
- Extrapulmonary TB: syphilis, cat-scratch disease, leishmaniasis, leprosy; rheumatoid disease; erythema nodosum, erythema induratum, syphilis, other mycobacterial infections

### DIAGNOSTIC TESTS & INTERPRETATION

#### Initial Tests (Immunogenesis)

To determine immune response to mycobacterium

- Tuberculin skin test (TST) (e.g., PPD): 5 U (0.1 mL) intermediate-strength intradermal injection into volar forearm. Measure induration at 48 to 72 hours:
  - PPD positive if induration

- >5 mm and HIV infection, recent TB contact, immunosuppressed, disease on x-ray
- >10 mm and age <4 years or other risk factors
- >15 mm and age >4 years and no risk factors
- Two-step test if no recent PPD, age >55 years, nursing home resident, prison inmate, or health care worker. Second test 1 to 3 weeks after initial test; interpret as usual.
- Context of PPD results:
  - False positive: BCG (unreliable, should not affect decision to treat)
  - False negative: HIV, steroids, gastrectomy, alcoholism, renal failure, sarcoidosis, malnutrition, hematologic or lymphoreticular disorder, very recent exposure
  - If positive once, no need to repeat.
  - No need for control with *Candida*/other
- Interferon- $\gamma$  release assays (IGRAs) measure interferon release after stimulation in vitro by *M. tuberculosis* antigens (2)[A]:
  - Lack of cross-reaction with BCG and most nontuberculous mycobacteria
    - IGRA is preferred (better specificity) for testing persons who have had BCG (vaccine or for cancer therapy) and for homeless persons, drug abusers and other groups with historically low rates of returning to have TST's interpreted (2)[A].
    - TST is still preferred if age <5 years (3)[A]. Either TST or IGRA may be used as periodic screening for persons in high-risk occupations and for recent contacts of persons with known or suspected active TB (2)[A].
    - Cotesting with TST and IGRA may be indicated when the initial test is negative but the risk for poor prognosis is increased (e.g., HIV-infected persons or children <5 years old) (2)[A].

### *Initial Tests-Active TB (lab, imaging)*

- Three consecutive sputum samples (8- to 24-hour intervals with at least one in early in the morning) for acid-fast bacilli (AFB) stain and culture by aerosol induction, gastric aspirate (children), or bronchoalveolar lavage
- Positive AFB: Treat immediately. Culture and sensitivity ultimately guide treatment.
- Chest radiograph
  - Primary TB: infiltrate with or without effusion, atelectasis, or adenopathy. Ghon lesion: calcified tuberculous caseating granuloma (tuberculoma); if associated with calcified

ipsilateral hilar lymph node then Ghon (or Ranke) complex

- Recrudescence TB: cavitary lesions and upper lobe disease with hilar adenopathy
- HIV: atypical findings with primary infection, right upper lobe atelectasis
- CT chest: good sensitivity, tree-in-bud (centrilobular nodules with branching linear opacities)

### *Follow-Up Tests & Special Considerations*

- Baseline CBC, creatinine, AST, ALT, bilirubin, alkaline phosphatase, visual acuity, and red-green color discrimination (regimens involving ethambutol)
- HIV: If positive, get baseline CD4 count.
- High risk: Check hepatitis B and C (injection drug users, Africa or Asia born, HIV infected).
- Extrapulmonary: urine, CSF, bone marrow, and liver biopsy for culture as indicated
- Nonspecific laboratory findings: anemia, monocytosis, thrombocytosis, hypergammaglobulinemia, SIADH, sterile pyuria

### *Diagnostic Procedures/Other*

- Culture: takes several weeks for definitive results
- Xpert MTB/RIF: The World Health Organization endorses use as the initial test for diagnosis of pulmonary TB and detection of rifampicin resistance in adults and children presumed to have MDR-TB, HIV-associated TB, or TB meningitis (4)[A]
  - Results are available within 2 hours (5).

## **TREATMENT**

### *GENERAL MEASURES*

- If clinical suspicion, treat immediately. Prescribing physician is responsible for treatment completion.
- Respiratory and droplet precautions
- Not infectious if favorable clinical response after 2 to 3 weeks of therapy and three negative AFB smears

### *MEDICATION*

Use ideal body weight for dosing. Directly observed therapy (DOT) strongly recommended for all,

## First Line

- LTBI
  - Isoniazid (INH) for 9 months at 5 mg/kg/day (max of 300 mg) *or* 15 mg/kg (max of 900 mg) 2 times per week (6)[A] *or*
  - INH 15 mg/kg + rifapentine 300 to 900 mg weekly for 12 weeks by DOT for patients age <sup>3</sup>12 years (6)[A]
- Active TB infection
  - Regimen 1 (preferred) (6)[A]
    - Initial phase:
      - INH 5 mg/kg, rifampin (RIF) 10 mg/kg (max 600 mg), pyrazinamide (PZA) 15 to 30 mg/kg, and ethambutol (EMB) 15 to 20 mg/kg daily for 8 weeks *or*
      - INH/RIF/PZA/EMB 5 days/week for 8 weeks
    - Continuation phase:
      - INH/RIF daily for 18 weeks; *or*, if DOT, INH/RIF 5 days/week for 18 weeks (recommended for HIV positive with CD4 <100 cells/mm<sup>3</sup> due to increased risk of resistance) *or*
      - INH/RIF 2 to 3 times per week for 18 weeks (not used if HIV positive with CD4 <100 cells/mm<sup>3</sup>; may have increased risk of relapse) *or* INH/rifapentine once weekly for 18 weeks (acceptable only for HIV patients without cavitary disease, may have increased risk of relapse) (6)[A]
  - Regimen 2
    - Initial phase:
      - INH/RIF/PZA/EMB daily for 2 weeks, then twice weekly for 6 weeks *or*
      - INH/RIF/PZA/EMB 5 days/week for 2 weeks, then twice weekly for 6 weeks
    - Continuation phase:
      - INH/RIF 2 to 3 times per week for 18 weeks (not recommended if HIV positive with CD4 <100 cells/mm<sup>3</sup>; may have increased risk of relapse) *or*

- INH/rifapentine once weekly for 18 weeks (acceptable only for HIV patients without cavitory disease; may have increased risk of relapse) (6)[A]
- Treat TB in pregnancy with INH, RIF, and EMB; add pyridoxine 25 mg/day.

## *Pregnancy Considerations*

- Streptomycin: ototoxic and nephrotoxic; do not use in pregnancy. Pyrazinamide is not used in pregnant women in the United States.
- Congenital infection: from maternal miliary or endometrial TB. PPD, CXR, lumbar puncture, and culture placenta. Start treatment promptly if suspected.
- Breastfeeding: OK while taking TB drugs; supplement with pyridoxine 25 mg/day.

## *Pediatric Considerations*

- Children: Ethambutol is not used.
- Children on medication may attend school.

## **ALERT**

- Maximum drug doses: RIF 600 mg all regimens, PZA 2,000 mg/day or 4,000 mg 2 times per week, EMB, 600 mg/day or 4,000 mg 2 times per week
- If patient does not receive PZA during entire first 2 months, extend treatment to 9 months.
- *M. bovis* is resistant to PZA; must be treated 9 months
- Continue EMB until organism susceptibility to INH plus RIF is determined (6)[A].

## *Second Line*

Fluoroquinolones and injectable aminoglycosides. Use when MDR is suspected or patient intolerance.

## **ISSUES FOR REFERRAL**

### **ALERT**

Notify public health authorities for all cases of active TB. Consult infectious disease specialist for cases of drug-resistant TB and for cases involving HIV-positive patients on antiretroviral therapy.

## **ADDITIONAL THERAPIES**

- Pyridoxine: 50 mg may prevent INH-associated peripheral neuropathy, especially for patients

who are malnourished or have comorbidities that increase risk of neuropathy (7)[A].

- Steroids: recommended for TB meningitis (8)[A] or pericarditis (8)[B], with concomitant anti-TB therapy

## ***SURGERY/OTHER PROCEDURES***

For extrapulmonary complications (spinal cord compression, bowel obstruction, constrictive pericarditis)

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Vitamin D deficiency may increase susceptibility to TB and development of active TB (9)[C]. There is conflicting evidence regarding the utility of vitamin D supplementation in TB treatment.

## ***INPATIENT CONSIDERATIONS***

- Negative pressure isolation with personal respirators and droplet precautions
- Three consecutive negative sputum AFB smears are necessary for release from isolation.

## ***Discharge Criteria***

Once TB has been excluded or the patient has effective therapy, is clinically improving, and is not an infectious risk, arrange outpatient follow-up with a provider comfortable managing TB and coordinate case management with local public health authorities.

## **ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

### **Patient Monitoring**

- Monthly visits to assess treatment adherence and adverse medication effects; CXR at 3rd month
- For HIV positive: CD4 count, CBC, and liver enzymes q3mo
- Liver enzymes monthly if chronic liver disease, alcohol use, pregnant, or postpartum. Temporarily halt medications if asymptomatic and enzymes  $\geq 5$  times normal or if symptomatic and enzymes  $\geq 3$  times normal.
- Visual acuity and red-green color monthly if on ethambutol  $>2$  months or doses  $>20$  mg/kg/day
- If culture-positive after 2 months of therapy, reassess drug sensitivity, initiate DOT, coordinate

care with public health authorities, and consider infectious disease consultation (if not already involved).

## PATIENT EDUCATION

- Emphasize medication adherence.
- Screen and treat close contacts.
- Alert patient that health authorities must be notified.
- <http://www.cdc.gov/tb/publications/factsheets/general/tb.htm>

## PROGNOSIS

Few complications and full resolution of infection if medications are taken for full course as prescribed

## COMPLICATIONS

- Cavitory lesions can become secondarily infected.
- Risk for drug resistance increases with HIV positive, treatment nonadherence, or residence in area with high incidence of resistance.
- MDR-TB: resistance to INH and rifampicin
- XDR-TB: resistant to fluoroquinolones (9% of MDR)

### ICD10

- A15.9 Respiratory tuberculosis unspecified
- A15.0 Tuberculosis of lung
- A19.9 Miliary tuberculosis, unspecified

# Clinical Pearls

**&NA;**

- Consider TB in patients with chronic cough and one additional risk factor.
- TB is fully curable when diagnosed and treated appropriately.
- Children and elderly clinically exhibit fewer classic features of TB.
- Involve public health authorities early in the diagnostic and treatment process for suspected cases of TB.

# TUBERCULOSIS, LATENT (LTBI)

Kay A. Bauman, MD, MPH

## BASICS

### DESCRIPTION

- Latent tuberculosis infection (LTBI) is an asymptomatic, noninfectious condition that follows exposure to an active case of tuberculosis. It is usually detected by a positive skin test (i.e., purified protein derivative [PPD]), positive interferon- $\gamma$  release assay (IGRA) test. In LTBI, acid-fast bacilli smear and culture are negative, and chest x-ray (CXR) does not suggest active TB.
- Tuberculosis (TB) is a common infection transmitted by inhaling airborne bacilli from a person with active TB. The bacilli multiply in the alveoli and are carried by macrophages, lymphatics, and blood to distant sites (e.g., lung, pleura, brain, kidney, bone).
- Active TB occurs in 5-10% of infected individuals not receiving preventive therapy. Chance of active TB increases with immunosuppression and is highest for all individuals within 2 years of infection; 85% of the cases are pulmonary, which spreads person-to-person via an aerosol route.
- The majority (66% in 2014) of active TB cases in the United States occur in foreign-born persons. Most are as the result of reactivation of LTBI (1). Active TB cases continue to decline but at a slower rate than in previous years.
- LTBI treatment is a key component of the TB elimination strategy of the United States.

### ALERT

Test for LTBI (PPD or IGRA), and treat latent infection in high-risk populations (1).

### EPIDEMIOLOGY

- High-risk groups include immigrants from Asia, Latin America, Africa, and the Pacific basin; homeless persons; persons with a history of drug use or history of incarceration; HIV-infected individuals; and health care workers.
- Also at high risk are those who are newly exposed (particularly children). In 2014, there were 9,412 new cases of TB in the United States (1).

- In 2014, Asians had the highest active TB case rate of all groups, 28.5 times the rate in whites. The rate of TB in Hispanics and in non-Hispanic blacks is 8 times higher than for whites (1).
- Of active TB cases in 2013 in ethnic minorities, 95% of Asian cases, 75% of Hispanic cases, 40% of black cases, and 23% of white cases were foreign-born (1). This highlights the need to screen foreign-born persons for latent TB and treat those with positive screening tests.
- In 2014, 55.3% of foreign-born persons with TB came from five countries: Mexico (20.6%), Philippines (12.1%), Vietnam (8.1%), India (7.7%), and China (6.8%) (1).
- In 2014, 6% of active TB cases in the United States were in HIV-positive individuals, 5% were homeless, 4% were incarcerated, and 2% in long-term care facilities (1).

## *Prevalence*

- 4% of the U.S. population has LTBI.
- 1/3 of the world's population is estimated to harbor latent TB.
- Predominant gender: male > female

## **ETIOLOGY AND PATHOPHYSIOLOGY**

*Mycobacterium tuberculosis, Mycobacterium bovis, and Mycobacterium africanum*

## **RISK FACTORS**

- HIV infection, immunosuppression
- Immigrants (from Asia, Africa, Latin America, Pacific Islands, or area with high rate of TB), including migrant workers
- Close contact with infected individual
- Institutionalization (e.g., prison, nursing home)
- Use of illicit drugs
- Lower socioeconomic status or homeless
- Health care workers
- Chronic medical disease such as diabetes mellitus (DM), end-stage renal disease, cancer, or silicosis; organ transplant (immunosuppression)
- Persons with fibrotic changes on CXR consistent with previous TB infection (2)
- Recent TB skin test (TST) converters (2)
- Laboratory personnel working with mycobacteria

## GENERAL PREVENTION

Screen for LTBI and treat individuals with positive tests.

## COMMONLY ASSOCIATED CONDITIONS

- HIV infection (see Initial Tests (lab, imaging))
- Immunosuppression

## DIAGNOSIS

### HISTORY

LTBI: Assess risk. History of immigration from a high-risk area, history of IV drug use and/or drug treatment, HIV, homelessness, recent incarceration, immunosuppression

### PHYSICAL EXAM

No active signs of infection on exam in patients with LTBI

### DIFFERENTIAL DIAGNOSIS

Fungal infections; atypical mycobacteria or *Nocardia*

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- None routinely recommended
- In higher risk patients: liver profile, hepatitis C virus (HCV), and hepatitis B virus (HBV) screening
- HIV test recommended to assess risk for active TB in men who have sex with men or persons with a history of IV drug use
- CXR to rule out active TB
- CT scan of the chest has good sensitivity (rarely needed).

### Diagnostic Procedures/Other

- Tuberculin Skin Test (TST): PPD: 5 U (0.1 mL) intermediate-strength intradermal volar forearm. Measure induration at 48 to 72 hours:
  - Positive if induration is

- >5 mm and patient has HIV infection (or suspected) (2), is immunosuppressed, had recent close TB contact, or has clinical evidence of active or old disease on CXR
- > 10 mm and patient age <4 years or has other risk factors noted earlier
- > 15 mm and patient age >4 years and has no risk factors (2)
- Negative if induration <5 mm on initial test and, if indicated, on second test
- Use the two-step test (administer a second intradermal test 1 to 3 weeks after initial test; measure and interpret as usual) if patient has had no recent PPD and is age >55 years or is a nursing home resident, prison inmate, or health care worker.
- Preferred for children <5 years.
- The interferon gamma release assays (IGRA) QuantiFERON-TB and QuantiFERON-TB GOLD; T-SPOT measure the release of interferon by sensitized lymphocytes when exposed to antigens of *M. tuberculosis*. It is unaffected by prior BCG vaccination, requires only one visit, and has improved sensitivity and specificity but is costly (3).
- Special considerations
  - Steroids: false-negative skin test
  - Measles vaccine: May suppress tuberculin activity; simultaneous PPD and measles vaccine recommended; if not simultaneous, defer PPD 4 to 6 weeks after measles vaccine.
  - The multiple-puncture tine test is not recommended.
  - Do not use history of BCG vaccination to ignore a positive PPD in adults and forego treatment.
  - Disorders that may alter results and give a falsenegative skin test:
    - Recent viral infection
    - New (< 10 weeks) infection
    - Severe malnutrition; HIV; anergy
    - Age <6 months
    - Overwhelming TB

## TREATMENT

### GENERAL MEASURES

- Must exclude active TB
- Treatment for LTBI is crucial to control and eliminate TB disease in the United States. LTBI treatment decreases the risk of active TB in those treated and decreases risks of potential spread to others (2).
- Treat LTBI at any age if patient has HIV, has had close TB contact, is a recent converter (<2 years), is an IV drug user, has an abnormal CXR, has a high-risk medical condition, or is in another highrisk group.
- Directly observed therapy (DOT) is recommended if patient adherence is not assured
  - Use isoniazid (INH) (for 9 months).
  - Acceptable alternative: INH for 6 months
  - Use INH 900 mg and rifapentine 900 mg weekly for 12 weeks.

P.1071

- Treat LTBI during pregnancy if patient has recent infection or is HIV positive (use INH with pyridoxine, and monitor liver enzymes); otherwise, treatment may be postponed until after delivery (2).
- Consult with public health or ID for HIV infection and suspected INH resistance (2).
- *Note:* Because of severe side effects associated with rifampin and pyrazinamide, these medications are less often recommended for LTBI treatment (2).
- Exclusions: cirrhosis, active hepatitis, history of excessive alcohol consumption (2)

## MEDICATION

- INH alone
  - INH-scored tablets: 100 mg, 300 mg, or syrup 10 mg/mL
    - Daily: adult 300 mg; pediatric 10 to 15 mg/kg (maximum 300 mg)
    - Twice weekly: adult 900 mg; pediatric 20 to 30 mg/kg (maximum 900 mg)
    - Treatment for 9 months; typical completion rates of <sup>2</sup>60%
    - Precautions
      - Follow liver function if the patient has history of alcoholism, HBV, HCV, or other liver dysfunction or new signs of liver injury.
      - INH: Peripheral neuritis and hypersensitivity are possible. Consider pyridoxine.
      - INH: An idiosyncratic drug reaction that results in INH-associated severe liver injury

was reported by the CDC in 17 patients from 2004 to 2008. Monitoring patients on treatment is recommended, looking for symptoms of liver injury (4).

- INH and rifapentine
  - Patients >12 years: rifapentine, a rifampin-like drug can be used to treat LTBI. 900 mg weekly (if patient >50 kg) and INH, 15 to 25 mg/kg weekly (rounded to nearest 50 or 100 mg; 900 mg max) for 12 weeks given as direct observation therapy. This new and shorter treatment has increased rates of completion compared with 9 months of INH (82% compared with 69% in one trial), slightly more adverse effects (4.9% vs. 3.7%), and is more costly.
    - Contraindications to INH/rifapentine: HIV patients receiving antiretroviral therapy, pregnancy. Rifapentine may cause hyperuricemia and hematuria (5).
- Alternative: rifampin alone
  - Adults 600 mg/day for 4 months; children 10 to 20 mg/kg/day for 6 months (max 600 mg/day). Fewer data exist for efficacy of this regimen but can be considered for contacts of INH-resistant TB or patient with INH contraindications. In one study, the 4-month course increased compliance from 62.6% with INH to 71.6% with rifampin (6).

## ADDITIONAL THERAPIES

### Pediatric Considerations

- Follow public health recommendations for assessing and treating newborn with mother/household contact with infection or disease.
- If mother or household contact has LTBI, skin test all household contacts, and treat any with positive PPD.
- If contact has abnormal CXR, separate infant until infectious status is known; if not contagious, monitor infant PPD (7).
- If mother has disease and is possibly contagious, evaluate infant for congenital TB and test for HIV; separate newborn until mother is noninfectious (7).
- Treat suspected congenital TB.
- If no congenital disease, start INH and repeat PPD after 3 to 4 months. If positive, reassess infant and finish 9 months of INH. If PPD is negative and source is noninfectious, stop INH and monitor infant (7).
- BCG vaccine, live-attenuated *M. bovis*: used more commonly in developing countries in children to prevent complications of TB

## *INPATIENT CONSIDERATIONS*

### **Geriatric Considerations**

- Before entering a chronic care facility, patients should have a PPD using two-step protocols.
- INH side effects are more pronounced.

### *Discharge Criteria*

- Activity, as tolerated
- No isolation required.

### **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### **Patient Monitoring**

- During preventive therapy for LTBI: initial monthly visits to assess adherence to regimen and to monitor for hepatitis and neuropathy; if stable, can monitor less frequently
- If patient remains asymptomatic, repeat of CXR is not needed.
- Check liver enzymes if patient is symptomatic, is HIV positive, has chronic liver disease, uses alcohol, or is pregnant or postpartum, and modify drugs, if needed.

### *DIET*

Regular. Consider pyridoxine, 10 to 50 mg/day.

### *PROGNOSIS*

- Generally, there are few complications and treatment is effective if medications are taken as prescribed.
- Retreatment is not necessary.

### **COMPLICATIONS**

Recrudescence TB

## See Also

&NA;

## Codes

**&NA;**

### ICD10

R76.11 Nonspecific reaction to skin test w/o active tuberculosis

## Clinical Pearls

**&NA;**

- An estimated 4% of the U.S. population have LTBI. Treatment of LTBI is crucial to control and eliminate TB disease in the United States.
- Test household contacts of PPD-positive patients.
- History of BCG vaccination, especially >10 years before PPD testing, should not be considered as the cause of a positive PPD. The interferon- $\gamma$  blood test is unaffected by prior BCG vaccination.
- Treat all HIV-positive patients with LTBI with a prophylactic regimen.
- Screen foreign-born persons for latent TB, and treat those who are positive.

# Typhoid Fever

Douglas W. MacPherson, MD, MSc-CTM, FRCPC

## BASICS

- A common enteric bacterial disease transmitted by ingestion of contaminated food or water
- Most cases in the United States are imported from endemic areas of South or Southeast Asia and Latin America.

## DESCRIPTION

- Typhoid fever is an acute systemic illness in humans caused by *Salmonella typhi*.
  - Classic example of enteric fever caused by *Salmonella* bacterium
- Enteric fevers due to *Salmonella paratyphi* can present in a manner similar to classic typhoid fever.
- Typhoid is endemic in developing nations with poor sanitation. Most cases in North America and other developed nations are acquired after travel to disease-endemic areas.
- Travelers visiting family or friends may be at greater risk of typhoid.
- Mode of transmission is fecal-oral through ingestion of contaminated food (commonly poultry or milk) or water.
- Incubation period varies from 7 to 21 days.
- System(s) affected: gastrointestinal; pulmonary; skin/exocrine
- Synonym(s): typhoid; typhus abdominalis; enteric fever; nervous fever; slow fever

## Geriatric Considerations

Disease is more serious in the elderly.

## Pediatric Considerations

Disease is more serious in infants but may be milder in children.

## EPIDEMIOLOGY

Although typhoid outbreaks have been described in the United States, most cases are reported in

international travelers returning from endemic transmission areas.

- Predominant age: all ages
- Predominant sex: male = female

## *Incidence*

In the United States, 300 to 500 new cases per year

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Historically, typhoid fever (untreated) occurs in several week-long stages.
- The initial infection is transmitted via the fecal-oral route, with resultant bacteremia and sepsis. Involvement of the bowel wall (Peyer patch) rarely may be associated with bleeding from the bowel or bowel perforation.
- The first stage involves fluctuations in temperature with relative bradycardia (Faget sign). Other symptoms include headache, cough, malaise, epistaxis, and abdominal pain.
- The second stage involves higher fever (with persistent relative bradycardia). Mental status changes are possible (agitationÑÑnervous feverÓ). Rose spots appear on the chest and abdomen. In some patients, abdominal pain is common as is constipation or diarrhea (with characteristic malodorous Òpea soupÓ appearance).
- The third week is when most complications occur due to intestinal hemorrhage or encephalitis.
- The final week is characterized by defervescence and recovery.
- A chronic carrier state may occur with *S. typhi* shedding in the stools. Potential person-to-person transmission may occur. In a chronic carrier state, *S. typhi* resides in the biliary tract and gallbladder. Chronic suppressive antimicrobials may clear the carrier state. In extreme cases, cholecystectomy has been performed as an attempt to clear carriage of *S. typhi*.

## **RISK FACTORS**

Consider in patients presenting with fever after tropical travel or exposure to a chronic carrier.

## **GENERAL PREVENTION**

- Food and water precautions help prevent all enteric infections, including typhoid fever.
- Avoid tap water, salad/raw vegetables, unpeeled fruits, and dairy products in tropical travel.
- Avoid undercooked poultry or poultry products left unrefrigerated for prolonged periods.
- Wash hands before and after food preparation.
- For high-risk travel to an endemic area, consider vaccination against typhoid (1)[A].

- Parenteral ViCPS or capsular polysaccharide typhoid vaccine (Typhim Vi) *or*
- Ty21a or live oral typhoid vaccine (Vivotif Berna), particularly if traveler will be at prolonged risk (>4 weeks)
- Consider vaccination for workers exposed to *S. typhi* or those with household or intimate exposure to a carrier of *S. typhi*.
- Occupational health and safety precautions, including screening of domestic and commercial food handlers, may be considered in some situations.

## DIAGNOSIS

Assess the clinical presentation and exposure history, including travel and known exposures to chronic *S. typhi* carriers.

### HISTORY

- Travel history to an endemic region and exposure to contaminated food or water
- Exposure to a chronic *S. typhi* carrier
- Fever, headache
- Malaise
- Abdominal discomfort/bloating/constipation
- Diarrhea (less common)
- Dry cough
- Confusion/lethargy

### PHYSICAL EXAM

- Fever
- Relative bradycardia
- Cervical adenopathy
- Conjunctivitis
- Rose spot (transient erythematous maculopapular rash in anterior thorax or upper abdomen)
- Splenomegaly
- Hepatomegaly

# DIFFERENTIAL DIAGNOSIS

- Malaria
- Enteric fever-like syndrome caused by *Yersinia enterocolitica*, pseudotuberculosis, and *Campylobacter* spp.
- Enteric fever caused by nontyphoid *Salmonella* spp.
- Infectious hepatitis
- Dengue
- Atypical pneumonia
- Infectious mononucleosis
- Subacute bacterial endocarditis
- Tuberculosis
- Brucellosis
- Q fever
- Toxoplasmosis
- Typhus
- Viral infections: Epstein-Barr virus (EBV), cytomegalovirus (CMV), viral hemorrhagic agents

## DIAGNOSTIC TESTS & INTERPRETATION

Due to the rarity of enteric fevers/typhoid syndromes in the United States, a high level of clinical suspicion is required.

- Definitive diagnosis is by culture of *S. typhi* from blood or other sterile body fluid.
- Isolation of *S. typhi* in sputum, urine, or stool leads to a presumptive diagnosis.
- Serology is nonspecific and typically not useful.
- If there are multiple negative blood cultures or in patients with prior antibiotic therapy, diagnostic yield is better with bone marrow culture.
- Anemia, leukopenia (neutropenia), thrombocytopenia, or evidence of disseminated intravascular coagulopathy. Elevated liver enzymes are common.
- Have a high clinical suspicion for intestinal perforation, or consider serial plain abdominal films looking for evidence of perforation in ill patients complaining of persistent abdominal tenderness.

## Diagnostic Procedures/Other

- Bone marrow aspirate for culture of *S. typhi* is more sensitive than blood cultures but rarely indicated as a primary investigation.
- Bone marrow aspiration may be done for evaluation of a fever of unknown origin.

## Test Interpretation

Classically, pathology of the bowel shows mononuclear proliferation involving lymphoid tissue of intestinal tract, especially Peyer patches of the terminal ileum.

## TREATMENT

- Treatment of typhoid disease and chronic carrier states must be determined on an individual basis. Factors to be considered include age, public health and occupational health risk (e.g., food handler, chronic care facilities, medical personnel), intolerance to antibiotics, and evidence of biliary tract disease.
- Awareness of emerging drug-resistant *S. typhi* strains and the epidemiology of the patient's exposure help direct primary therapy. Knowledge of local resistance patterns for presumptive treatment or laboratory sensitivity also guide therapy. Fluoroquinolone-resistant *S. typhi* is common in Asia.

---

P.1073

## GENERAL MEASURES

- Fluid and electrolyte support
- Strict isolation of patient's linen, stool, and urine
- Consider serial plain abdominal films for evidence of perforation, usually in the 3rd to 4th week of illness.
- For hemorrhage: blood transfusion and management of shock

## MEDICATION

### First Line

- Chloramphenicol: pediatric 50 mg/kg/day PO QID for 2 weeks; adult dose 2 to 3 g per day PO divided q6h for 2 weeks *or*
- Ampicillin: pediatric 100 mg/kg/day (max 2 g) QID PO for 2 weeks; adults 500 mg q6h for 2 weeks *or*

- Ciprofloxacin: 500 mg PO BID for 2 weeks, *indicated in multiple-drug-resistant typhoid*
  - Has been used safely in children; WHO recommends as first line in areas with drug resistance to older first-line antibiotics.
  - Fluoroquinolones may prevent clinical relapse better than chloramphenicol (2)[A].
- Ceftriaxone: pediatric 100 mg/kg/day for 2 weeks; adult dose: 1 to 2 g IV once daily for 2 weeks *or*
- Azithromycin: pediatric 10 to 20 mg/kg (max 1 g) PO daily for 5 to 7 days; adult dose: 1 g PO once followed by 500 mg PO daily for 5 to 7 days
- Chronic carrier state
  - Ampicillin: 4 to 5 g/day plus probenecid 2 g/day QID for 6 weeks (for patients with normal gallbladder function and no evidence of cholelithiasis)
  - Ciprofloxacin: 500 mg PO BID for 4 to 6 weeks is also efficacious. Chloramphenicol resistance has been reported in Mexico, South America, Central America, Southeast Asia, India, Pakistan, Middle East, and Africa.
- Contraindications: Refer to manufacturer's profile.
- Precautions: Rarely, Jarisch-Herxheimer reaction appears after antimicrobial therapy.
- Significant possible interactions: Refer to manufacturer's profile for each drug.

## *Second Line*

- Trimethoprim-sulfamethoxazole one doublestrength tablet twice a day for 10 days (Note: Drug resistance is common, local resistance patterns and expert knowledge should guide choice of treatment agent.)
- Furazolidone: 7.5 mg/kg/day PO for 10 days; in uncomplicated multidrug-resistant typhoid; safe in children; efficacy >85% cure

## *Pregnancy Considerations*

Ciprofloxacin therapy is relatively contraindicated in children and in pregnant patients.

## *ISSUES FOR REFERRAL*

Complications of sepsis, bowel perforation

## *SURGERY/OTHER PROCEDURES*

- Complications: bowel perforation

- Cholecystectomy may be warranted in carriers with cholelithiasis, relapse after therapy, or intolerance to antimicrobial therapy.

## *INPATIENT CONSIDERATIONS*

### **Admission Criteria/Initial Stabilization**

- Inpatient if acutely ill
- Outpatient for less ill patient or for carrier

### *Nursing*

Observe enteric precautions.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Bed rest initially, then activity as tolerated

### *Patient Monitoring*

See òGeneral Measures.ó

### *DIET*

NPO if abdominal symptoms are severe. With improvement, begin normal low-residue diet, with high-calorie supplementation if malnourished.

### *PATIENT EDUCATION*

- Discuss chronic carrier state and its complications.
- For family members, travelers, or workers at risk, educate about food/water hygiene and provide vaccination.
- Educate patients that the typhoid vaccines do not protect against *S. paratyphi* infection.
- Typhoid vaccines protect 50-80% of recipients (not 100%) with diminishing effectiveness over 2 to 4 years.
- CDC patient handout: <http://www.cdc.gov/vaccines/hcp/vis/vis-statements/typhoid.html>

### *PROGNOSIS*

Overall prognosis is good with therapy, <2% mortality rate, 15% relapse rate with some

antibiotic treatments, and 3% bowel perforation.

## COMPLICATIONS

- Intestinal hemorrhage and perforation in distal ileum
- Patients (up to 3%) may become chronic carriers/persistent stool excretor of *S. typhi* for >1 year.
- Seeding of the biliary tract may become a focus for relapse of typhoid fever: most common in females and older patients (>50 years of age)
- Osteomyelitis is more common in patients with sickle cell anemia, systemic lupus erythematosus, and hematologic neoplasms, as well as in immunosuppressed hosts.
- Endovascular infection in the elderly and in patients with a history of bypass operation or aneurysm
- Rarely, endocarditis or meningitis

## Codes

**&NA;**

### ICD10

- A01.00 Typhoid fever, unspecified
- Z22.0 Carrier of typhoid
- A01.03 Typhoid pneumonia

## Clinical Pearls

**&NA;**

- Consider typhoid (along with malaria, dengue, and other travel-associated infections) in febrile travelers returning from endemic areas such as Latin America, sub-Saharan Africa, or South Asia.
- Routine blood cultures detect *S. typhi* but may be negative if antibiotics are administered prior

to testing.

- A history or documentation of vaccination against *S. typhi* does not exclude the diagnosis of typhoid fever.

# Typhus Fevers

Douglas W. MacPherson, MD, MSc-CTM, FRCPC

## BASICS

Typhus is an infectious disease syndrome caused by several rickettsial bacterial organisms resulting in acute, chronic, and recurrent disease (1)[C].

## DESCRIPTION

- Acute infection caused by three species of *Rickettsia*
  - Epidemic typhus: human-to-human transmission by body louse; primarily in setting of refugee camps, war, famine, and disaster. Recurrent disease occurs years after initial infection and can be a source of human outbreak. Flying squirrels are a reservoir.
  - Endemic (murine) typhus: spread to humans by rat flea bite
  - Scrub typhus: infection and infestation of chiggers and of rodents to humans by the chigger; primarily in Asia and western Pacific areas
- System(s) affected: endocrine/metabolic; hematologic/lymphatic/immunologic; pulmonary; skin/exocrine
- Synonym(s): louse-borne typhus; Brill-Zinsser disease; murine typhus

## EPIDEMIOLOGY

- Epidemic and endemic typhus: rare in the United States (outside of South Texas)
- Scrub typhus: travelers returning from endemic areas only (rare)

## Incidence

Endemic typhus: <100 cases annually, primarily in states around the Gulf of Mexico, especially South Texas; underreporting suspected

## ETIOLOGY AND PATHOPHYSIOLOGY

- Epidemic typhus by *Rickettsia prowazekii*
- Endemic typhus by *Rickettsia typhi*

## RISK FACTORS

- Vector exposure
- Travel to endemic countries

## Geriatric Considerations

Elderly may have more severe disease.

## GENERAL PREVENTION

Vector control:

- Scrub typhus: Wear protective clothing and use insect repellents.
- Endemic typhus: Practice ectoparasite and rodent control.
- Epidemic typhus: delousing and cleaning of clothing; vaccine for those at high risk of exposure (typhus vaccine production has been discontinued in the United States)

## DIAGNOSIS

Typhus syndromes are rare in the United States. A high level of clinical suspicion is necessary.

### HISTORY

Travel or other risk exposure

- Fever, chills
- Intractable headache
- Myalgias, malaise
- Cough, rash, ocular pain

## PHYSICAL EXAM

- General
  - Fever
  - Relative bradycardia (scrub typhus)
- Epidemic typhus
  - Incubation period ÷ 1 week

- Macular or maculopapular rash beginning on trunk ÷ 5th day of illness
- Nonproductive cough
- Pulmonary infiltrates
- Endemic typhus
  - Incubation period 1 to 2 weeks
  - Macular or maculopapular rash beginning on trunk 3rd to 5th day of illness
- Scrub typhus
  - Incubation period 1 to 3 weeks
  - Eschar at bite site
  - Regional lymphadenopathy
  - Generalized lymphadenopathy
  - Splenomegaly
  - Macular or maculopapular rash beginning on trunk approximately 5th day of illness
  - Relative bradycardia early in disease
  - Ocular pain
  - Conjunctival injection

## *DIFFERENTIAL DIAGNOSIS*

- Other rickettsial disease: Rocky Mountain spotted fever; ehrlichiosis; Mediterranean spotted fever (boutonneuse fever) (*Rickettsia conorii*)
- Bacterial meningitis; meningococemia
- Measles, rubella
- Toxoplasmosis
- Leptospirosis
- Typhoid fever
- Dengue, malaria
- Relapsing fever
- Secondary syphilis
- Viral syndromes: mononucleosis, acute retroviral syndrome

## DIAGNOSTIC TESTS & INTERPRETATION

- Specific serologies with rising antibody titer
- If suspected, isolate *Rickettsia* in qualified laboratory to minimize the risk of laboratory-acquired infection.
- CDC Rickettsial Zoonoses Branch 404-639-1075.

### *Initial Tests (lab, imaging)*

- CBC often normal
- Weil-Felix serologic reaction may be positive; test value hampered by low sensitivity and nonspecificity; epidemic and endemic typhus, 4-fold titer rise or titer >1/320 to OX-19; scrub typhus, 4-fold rise in titer to OX-K
- Hyponatremia in severe cases
- Hypoalbuminemia in severe cases
- Recent antibiotic exposure may alter lab results.

### *Test Interpretation*

Diffuse vasculitis on skin biopsy

## TREATMENT

Initiate treatment based on epidemiologic risk and clinical presentation.

## GENERAL MEASURES

- Skin and mouth care
- Supportive care for the severely ill, directed at complications

---

P.1075

## MEDICATION

### First Line

- Begin treatment when diagnosis is likely and continue until clinically improved and the patient is afebrile for at least 48 hours; usual course is 5 to 7 days.
- Children <sup>3</sup>8 years of age and adults

- Doxycycline IV/PO: adults 100 mg q12h, children  $\leq 45$  kg: 5 mg/kg/day divided twice daily (max of 200 mg/day);  $>45$  kg: adult dosing
- Children  $\geq 8$  years of age: Risk of dental staining from tetracyclines is minimal with short courses of therapy.
- Tetracycline: 25 mg/kg PO initially, then 25 mg/kg/day in equally divided doses q6h
- Children  $\geq 8$  years of age, pregnant women, or if typhoid fever is suspected
  - Chloramphenicol: 50 mg/kg PO initially, then 50 mg/kg/day in equally divided doses q6h
  - If severely ill, chloramphenicol sodium succinate: 20 mg/kg IV initially, infused over 30 to 45 minutes, then 50 mg/kg/day infused in equally divided doses q6h until orally tolerable
  - Azithromycin, fluoroquinolones, and rifampin may be alternatives depending on the clinical scenario.
- Precautions: Refer to the manufacturer's profile for each drug.
- Significant possible interactions: Refer to the manufacturer's profile for each drug.

## *Second Line*

- Doxycycline: single oral dose of 100 or 200 mg orally for those in refugee camps, victims of disasters, or in the presence of limited medical services
- Isolated reports indicate that erythromycin and ciprofloxacin are effective.
- Azithromycin 1,000 mg orally once a day for 3-day course is effective for scrub typhus; better tolerated than doxycycline but more expensive
- Rifampin may be effective in areas where scrub typhus responds poorly to standard antirickettsial drugs.

## *ISSUES FOR REFERRAL*

Infectious disease consultation is recommended. Contact CDC and local public health authorities.

## *INPATIENT CONSIDERATIONS*

### **Admission Criteria/Initial Stabilization**

- Outpatient care unless severely ill
- Severely ill or constitutionally unstable (e.g., shock)

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### **Patient Monitoring**

- Admit severely ill patients.
- If treated as an outpatient, ensure regular follow-up to assess clinical improvement and resolution.

#### *DIET*

As tolerated

### *PATIENT EDUCATION*

Travel advice (minimize exposure risks, vector avoidance, vaccination as appropriate)

### *PROGNOSIS*

- Recovery is expected with prompt treatment.
- Relapses may follow treatment, especially if initiated within 48 hours of onset (this is *not* an indication to delay treatment). Treat relapses the same as primary disease.
- Without treatment, the mortality rate of typhus is 40-60% for epidemic, 1-2% for endemic, and up to 30% for scrub disease.
- Mortality is higher among the elderly.

### **COMPLICATIONS**

Organ-specific complications (particularly in the second week of illness): azotemia, meningoencephalitis, seizures, delirium, coma, myocardial failure, hyponatremia, hypoalbuminemia, hypovolemia, shock, and death

### **REFERENCES**

## Codes

&NA;

### ICD10

- A75.9 Typhus fever, unspecified
- A75.0 Epidemic louse-borne typhus fever d/t Rickettsia prowazekii
- A75.2 Typhus fever due to Rickettsia typhi

## Clinical Pearls

**&NA;**

- Consider typhus (along with malaria and dengue) in febrile travelers returning from endemic areas.
- Rickettsial infections typically present within 2 to 14 days. Febrile illnesses presenting with onset >18 days after travel are unlikely to be rickettsial.
- Routine blood cultures do not detect *Rickettsia*.
- Prior vaccination does not exclude the diagnosis of typhus.

# Ulcer, Aphthous

Jay A. Brieler, MD

## BASICS

### DESCRIPTION

- Self-limited, painful ulcerations of the nonkeratinized oral mucosa, which are often recurrent
- Synonyms: canker sores; aphthae; aphthous stomatitis
  - Comes from *aphth* meaning *ÙlcerÓ* in Greek; first used by Hippocrates between 460 and 370 BC to categorize oral disease (1)
- Categorization
  - Minor aphthous ulcers (2)
    - Usually <10 mm in diameter
    - Self-limited, healing within 4 to 14 days
    - Rarely affect the dorsum of the mouth
    - Nonscarring
  - Major aphthous ulcers (Sutton disease) (2)
    - Usually >10 mm in diameter
    - Can affect the dorsum of the mouth
    - May take weeks to months to heal
    - Generally more painful than minor aphthous ulcers
    - May cause scarring
  - Herpetiform ulcers (2)
    - Usually 2 to 3 mm in diameter, may coalesce to form larger ulcerations
    - Unrelated to viral-caused herpetic stomatitis
    - Occur in small clusters numbering 10s to 100s, lasting 1 to 4 weeks
    - Generally more painful than minor aphthous ulcers

- May cause scarring

## ***EPIDEMIOLOGY***

- Most frequent chronic disease of the oral cavity, affecting 5-25% of the population (3)
- More common in patients between 10 and 40 years of age, women, Caucasians, nonsmokers, professional students, and those of higher socioeconomic status (3)
- Less frequent with advancing age (4)
- Minor aphthous ulcers
  - Most common: 70-85% of all aphthae
- Major aphthous ulcers
  - 10-15% of all aphthae
- Herpetiform
  - Least common: 10% of all aphthae

## ***Prevalence***

Lifetime prevalence of 5-60% (3)

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

Likely multifactorial; association with stress-induced rise in salivary cortisol, multiple HLA antigens, cell-mediated immunity; exact etiology unknown (4)

## ***RISK FACTORS***

- Genetic factors: Offspring of those with recurrent aphthous ulcers have a 90% chance of developing recurrent aphthous stomatitis (RAS) (5)[C].
- Local trauma: sharp teeth, dental treatments, or mucosal injury secondary to toothbrushing
- Increased stress and anxiety
- Nutritional deficiencies: iron, zinc, vitamin B complex, and folate
- Homocysteinemia (6)[B]
- Immunodeficiency
- Recent cessation of tobacco use
- Food sensitivity: to benzoic acid/cinnamaldehyde

- Medications
  - NSAIDS
  - *&bgr;*-Blockers
  - Alendronate
  - Methotrexate
- Neutropenia
- Anemia
- Endocrine alterations (i.e., menstrual cycle) (2)
- Psychosocial stress

## DIAGNOSIS

Diagnosis is made by history and clinical presentation. Lab work is rarely helpful to diagnose aphthous ulcers (2)[A].

### HISTORY

- May experience prodrome of burning sensation of oral mucosa 2 to 48 hours prior to appearance of ulcers
- Patients typically complain of oral ulcerations, which are painful and exacerbated by movement of the mouth. Exacerbation may also be reported with certain foods (hot, spicy, acidic, or carbonated foods or drinks) (2)[A].
- Ask about ulcerative lesions of other anatomic areas, family history, or prior history of aphthous ulcers (2)[A].

### PHYSICAL EXAM

- Round or ovoid ulcerations generally <10 mm in size. Covered with a grayish-white pseudomembrane surrounded by an erythematous halo (3)[A]
- Ulcers are typically found in the buccal or lip mucosa, ventral tongue, soft palate, or oral vestibule. Rarely on the dorsum of the mouth/lips
- Evaluate for signs of secondary infection: elevated temperature, increased surrounding edema, or pus drainage

### DIFFERENTIAL DIAGNOSIS

## Oral trauma

- Biting
- Dentures
- Infection
  - Herpes virus (herpetic stomatitis): vesicular lesions on keratinized tissue (dorsal tongue, vermillion border). Generally not present on mucosa (5)[C]
  - HIV: Ulcerations have lengthened healing time and tend to be more painful (5)[C].
- Mucocutaneous disease; especially if chronic or nonhealing
  - Lichen planus
  - Pemphigus
- Malignancy: Investigate and closely monitor nonhealing lesions, especially those with ipsilateral cervical lymphadenopathy.
- Important to evaluate for underlying systemic disease, causing aphthous-like ulcerations
  - Highest suspicion in adult patients with their initial episode or in individuals with additional lesions elsewhere in the body (3)[A],(4)[C]
  - Behçet syndrome: autoimmune systemic vasculitis usually involving mucous membranes
    - Genital and oral ulceration
    - Uveitis
  - Reiter syndrome: reactive arthritis, preceded by infection, usually of the genital tract (2)[A]
    - Uveitis
    - Urethritis
    - HLA-B27-associated arthritis
  - Sweet syndrome: acute neutrophilic dermatitis (5)[C]
    - Fever, sudden onset
    - Erythematous skin plaques/papules, well-demarcated
    - Leukocytosis
    - 50% of patients have an associated malignancy
    - Most often in middle-aged females

- Inflammatory bowel disease (IBD): Crohn disease, ulcerative colitis
  - 10% of patients with Crohn disease experience recurrent oral ulcers (5)[C].
  - Bloody or persistent diarrhea
  - Weight loss
- Cyclic neutropenia (5)[C]
  - Recurrent fevers associated with infections, occasionally occurring intraorally.
  - Begins in childhood
- Systemic lupus erythematosus (SLE): autoimmune vascular collagen disease
  - Oral lesions have great variability, including recurrent ulceration.
- Gluten-sensitive enteropathy (celiac disease)
  - Weight loss and signs of malabsorption
  - Bloating and diarrhea

## ***DIAGNOSTIC TESTS & INTERPRETATION***

May consider complete blood count, folic acid, ferritin, vitamin B<sub>12</sub> to evaluate for systemic causes based on presentation (2)[A]

## **Follow-Up Tests & Special Considerations**

- HIV is associated with increased amount of ulcers and increased healing time.
- Biopsy and viral cultures for nonhealing ulcers or atypical presentations
- Rheumatologic serology if underlying systemic disease is suspected.

---

P.1077

## **TREATMENT**

### ***GENERAL MEASURES***

- Management is symptomatic. Goal is to reduce inflammation and relieve pain.
- Avoid potentially irritating food or drink:
  - Spicy

Acidic

- Hot
  - Carbonated beverages.
  - Abrasive/hard foods (i.e., chips, nuts, etc.)
- Behavior modification to reduce dental trauma with toothbrush or bruxism

## **MEDICATION**

In general, the goals of treatment depend on the extent of ulceration and frequency of outbreaks.

### **First Line**

- Topical corticosteroids (to improve healing time and symptoms) (2)[A]
  - Adverse effects: may increase risk of oral candidiasis (more likely with higher potency formulations)
  - Preparations
    - Triamcinolone 0.1% dental paste
      - Apply sparingly to ulcers three times daily for up to 2 weeks or until ulcer resolution.
    - Fluocinonide 0.05% gel or ointment
      - Apply sparingly to ulcer four times daily for up to 2 weeks or until ulcer resolution.
    - Dexamethasone 5 mg/5 mL elixir
      - Rinse for 3 minutes and spit four times daily until ulcer resolution.
- Topical anesthetics (to reduce symptoms only) (2)[A]
  - Adverse effects: may cause initial stinging
  - Preparations
    - Lidocaine 2% gel
      - Apply four times daily or prior to eating as needed for pain, for up to 2 weeks or until ulcer resolution.
- Antimicrobial mouth rinses (improve healing time, decrease pain, and may prevent recurrence)
  - Preparations

Chlorhexidine aqueous mouthwash 0.12% or 0.2%

- Use four times daily for up to several months.
  - May cause superficial tooth staining
- Topical immunomodulators (improves healing time, reduces symptoms, and prevents recurrence when used in prodromic phase) (2)[A]
    - Adverse effects: may cause stinging sensation
    - Preparation
      - Amlexanox 5% oral paste
        - Apply to ulcers four times daily for up to 2 weeks or until ulcer resolution.

## *Second Line*

- Systemic corticosteroids rescue therapy in acute, severe, recurrent outbreaks (2,3)[A]
  - Prednisone 25 mg/day, then tapered over 2 months (3)[A]
- Colchicine, pentoxifylline, thalidomide, and dapsone have been used with variable success but should be used with caution due to side effects (2,3,4)[A].

## *ISSUES FOR REFERRAL*

Otolaryngology or dental referral if lesions have not resolved as expected.

## *ADDITIONAL THERAPIES*

Vitamin B<sub>12</sub> supplementation has been shown to decrease burden of outbreaks and recurrence, independent of preexisting deficiency in one small study (7)[B]. Multivitamins have not been shown to be effective (8)[B].

## *SURGERY/OTHER PROCEDURES*

Chemical cautery with silver nitrate (reduces ulcer pain but not healing time) (9)[B]

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Some small cohort studies show clinical improvement with minimal side effects of several herbal and alternative treatments (3)[A].

- *Glycyrrhiza* (licorice) (10)[B]
- *Myrtus communis* (myrtle) (11)[B]

- Bee propolis (3)[A]

## Codes

&NA;

### ICD10

K12.0 Recurrent oral aphthae

## Clinical Pearls

&NA;

- Aphthous ulcers are the most common chronic disease of the oral cavity.
- Most cases are mild, self-limited episodes.
- Appropriate treatment should be aimed at symptom control and promotion of healing.
- If lesions are nonhealing, simultaneously occur elsewhere in the body, or when patients present with a sudden initial episode in adulthood, it is imperative to rule out secondary causes.

# Ulcerative Colitis

Jason E. Domagalski, MD, FAAFP

## BASICS

### DESCRIPTION

- Chronic idiopathic inflammatory disease of the colonic mucosa that can affect any section of the colon starting at the rectum with variable extension towards the cecum
- >95% of patients have rectal involvement, 50% have disease limited to rectum and sigmoid; 20% have pancolitis.

### EPIDEMIOLOGY

#### *Incidence*

- United States: 9 to 12 new cases/100,000 persons/year
- Incidence stable over the past 5 decades
- Predominant age: 15 to 35 years; second and smaller peak in the 7th decade
- Predominant sex: female > male (slight)

#### *Prevalence*

205 to 240/100,000 persons

#### *Pregnancy Considerations*

- Increased risk of preterm delivery and small for gestational age birth
- 30% with inactive disease relapse in pregnancy
- Patients should delay pregnancy until disease is inactive for at least 3 months.

### ETIOLOGY AND PATHOPHYSIOLOGY

Unknown; hypotheses include allergy to dietary components and abnormal immune responses to bacterial or "self" antigens; final common path is mucosal inflammation secondary to immune cell infiltration.

## *Genetics*

- Family history in 5-10% in population surveys and 20-30% in referral-based studies
- 50-60% concordance rate in identical twin studies
- Associations with interleukin 23/Th17 pathway, interleukin 10, and interferon gamma genes

## *RISK FACTORS*

- Better sanitation, indoor work environments, and fatty foods increase risk.
- NSAID use > 15 days per month associated with increased risk
- Appendectomy protects against late disease onset.
- Negative association with smoking: Relative risk of smokers is 40% of nonsmokers.

## *GENERAL PREVENTION*

- Increased risk for colon cancer w/o colectomy
- Aspirin (300 mg/day) and ursodeoxycholic acid (10 mg/kg/day) are preventive.

## *Pediatric Considerations*

- Breastfeeding may protect against pediatric inflammatory bowel disease (IBD).
- More likely pancolonic at onset and shorter time from diagnosis to colectomy (median 11.1 years)

## *COMMONLY ASSOCIATED CONDITIONS*

- Extracolonic manifestations in 10-15%
- Arthritides, including large joint arthritis, sacroiliitis, and ankylosing spondylitis
- Pyoderma gangrenosum
- Episcleritis and uveitis
- Asymptomatic fatty liver (common)
- Primary sclerosing cholangitis: 1-4%
- Cirrhosis of liver: 1-5%
- Bile duct carcinoma
- Thromboembolic disease: 1-6%

# DIAGNOSIS

## HISTORY

- Bloody diarrhea; tenesmus; abdominal pain; rectal urgency, occasional fecal incontinence; weight loss; arthralgias
- Grading: Mild (rectal bleeding with <4 bowel movements/day); Moderate (rectal bleeding with >4 bowel movements/day); Severe (rectal bleeding with >4 bowel movements/day and systemically ill [albumin <30g/L])

## PHYSICAL EXAM

- Arthralgias and arthritis: 15-40%
- Spondylitis: 3-6%
- Ocular: 4-10%; includes uveitis, cataracts, keratopathy, and central serous retinopathy
- Dermatologic: erythema nodosum, pyoderma gangrenosum
- Pulmonary: pleuritis
- Aphthous ulcers of mouth: 5-10%

## DIFFERENTIAL DIAGNOSIS

- Hemorrhoids, neoplasms, colonic diverticula, arteriovenous malformation, Crohn disease
- Infectious diarrhea, including bacterial (enterotoxigenic *Escherichia coli*), *Clostridium difficile* colitis, and parasitic (*Entamoeba histolytica*)
- Herpes simplex, *Chlamydia trachomatis*, *Cryptosporidium*, *Isospora belli*, cytomegalovirus
- Radiation proctitis; ischemic colitis

## DIAGNOSTIC TESTS & INTERPRETATION

- Anemia (chronic disease ± iron deficiency)
- Leukocytosis during exacerbation
- Elevated ESR and CRP
- Electrolyte abnormalities, especially hypokalemia
- Hypoalbuminemia, elevated LFTs
- Perinuclear antineutrophil cytoplasmic antibody (pANCA) is elevated in 60-70% of cases, also found in 40% of patients with Crohn disease. Sensitivity 33%, specificity 97%

## *Initial Tests (lab, imaging)*

- Plain abdominal films
  - Obtain immediately if significant abdominal tenderness, fever, and leukocytosis for early diagnosis of toxic megacolon and perforation.
- Upper GI series with small bowel follow-through to rule out Crohn disease.
- Ultrasound, MRI, scintigraphy, and CT may have similar accuracy in diagnosis of IBD (1)[A].
- Stool culture and stool testing for parasites to rule out infectious colitis (2)[C]
- *C. difficile* antigen if recent antibiotics

## *Diagnostic Procedures/Other*

- Sigmoidoscopy (may include biopsy) is often sufficient to make initial diagnosis.
- Colonoscopy (may include biopsy)
  - Evaluate premalignant features; differentiate from Crohn disease; investigate stricture/mass; define extent and location of disease.
- Full colonoscopy contraindicated in severe, active disease/colonic dilatation (risk of perforation)

## *Test Interpretation*

Inflammation of the colonic mucosa with ulcerations:

- Ulcerations are hyperemic and hemorrhagic.
- Mucosal separation, distortion, and atrophy of the crypts on histology (2)[C]
- Extends proximally, without skips
- May affect terminal ileum, so-called backwash ileitis

## **TREATMENT**

Management involves acute treatment of inflammatory symptoms, followed by maintenance of remission; therapeutic approach is determined by symptom severity and the extent of colonic involvement.

- 5-aminosalicylic acid (5-ASA) is effective for inducing remission in mild to moderate disease (NNT = 6) and preventing relapse in quiescent disease (NNT = 4) (3)[A]:

Topical mesalamine is superior to oral aminosalicylates and topical steroids for proctitis (3) [A].

- Combination of oral and topical aminosalicylates is more effective than either alone.
- Corticosteroid therapies are effective for inducing remission in active disease (NNT = 3) (3)[A].
- Azathioprine or 6-mercaptopurine (6-MP) reduce relapse in patients with quiescent disease (NNT = 4) (3)[A].
- Maintenance of remission in mild to moderate distal disease with the following: mesalamine suppositories for proctitis or enemas for distal colitis, sulfasalazine, balsalazide, or combination oral and topical mesalamine (3)[A]
- Maintain remission in mild to moderate extensive disease with sulfasalazine, olsalazine, mesalamine, and balsalazide (3)[A].
- Infliximab is effective at inducing remission in ambulatory patients with moderate to severely active disease (NNT = 4) (3)[A].

## GENERAL MEASURES

Control inflammation, prevent complications, and replace nutritional losses and blood volume.

## MEDICATION

### *First Line*

- Sulfasalazine
  - Uncoated tablets. Adults: initial: 1 g PO q6-8h; maintenance: 500 mg PO q6h; children <sup>3</sup>6 years: initial: 40 to 60 mg/kg/day PO in 3 to 6 divided doses; maintenance: 30 mg/kg/day PO divided q6h (max 2 g/day)
  - Enteric-coated tablets. Adults: initial: 3 to 4 g/day PO in divided doses q6-8h; maintenance: 2 g/day PO in divided doses; children <sup>3</sup>6 years: initial: 40 to 60 mg/kg/day PO in 3 to 6 divided doses; maintenance: 30 mg/kg/day PO in 4 divided doses (max 2 g/day)
- Mesalamine
  - Oral delayed-release tablets (Asacol HD) to induce remission; adults: 800 mg PO TID for 6 weeks
  - Oral controlled-release tablets (Pentasa) for maintenance of remission; adults: 1 g PO QID
  - Single daily dose available for mesalamine (Lialda; acute therapy 4.8 g once daily or 2.4 g once daily for maintenance) and (Apriso; 1.5 g once daily; approved in the United States ONLY for maintenance)

- Once daily dosing is as effective as conventional TID dosing for mild to moderately active UC treatment and to maintain remission (4)[A]
- 5-ASA (e.g., mesalamine) enemas and suppositories to treat proctitis/proctosigmoiditis:
  - Suppositories: (Canasa) adults: 1,000 mg per rectum at bedtime for 3 to 6 weeks

---

- Enemas: adults: 4 g per rectum, retained for 8 hours each night; use for 3 to 6 weeks or until remission is achieved.
- Balsalazide: adults: 2.25 g PO TID for total daily dose of 6.75 g for 8 to 12 weeks; children/adolescents: 2.25 g PO TID for total daily dose of 6.75 g or 750 mg PO TID for total daily dose of 2.25 g for 8 weeks
- Olsalazine: adults: 500 mg PO BID (up to 3 g/day); children >2 years old: 30 mg/kg/day in 2 divided doses (up to 2 g/day), primarily used for maintenance

P.1079

## *Second Line*

- Prednisone for severe exacerbations: adult dosage: initial: 40 to 60 mg/day PO (max 1 mg/kg/day) for 7 to 10 days; taper over 2 to 3 months; can be given IV in hospitalized patients
- Infliximab is effective in patients whose disease is refractory to conventional treatment (3,5) [A]:
  - Adult dose: 5 mg/kg IV at weeks 0, 2, and 6 for induction, then maintenance of 5 mg/kg IV is given every 8 weeks
- Adalimumab: for moderate to severe ulcerative colitis refractory to steroids and azathioprine/6-MP. Initial dose: 160 mg SC (given as four injections on day one or two injections daily over 2 consecutive days; limit injections to 40 mg per injection); 2nd dose 2 weeks later: 80 mg, and maintenance: 40 mg every other week thereafter; should only be continued if evidence of remission by 8 weeks (5)

## *Pediatric Considerations*

- Infliximab can increase the risk of cancer in children; weigh risks versus benefits.
- Immunomodulators can be used in children unresponsive to steroids and aminosalicylates or who cannot be weaned from high-dose steroids:
  - Daily abdominal plain films until improvement
  - If dilatation of colon increases or treatment has failed to attain reversal in 72 hours, surgical consultation for emergency colectomy is indicated.

## SURGERY/OTHER PROCEDURES

- Indicated for medically refractory disease (particularly with high-dose steroids)
- May be emergent for massive hemorrhage, perforation, and toxic dilatation of the colon. The emergency surgery of choice is total or subtotal abdominal colectomy with end ileostomy.
- Surgery is also indicated for cancer/multisite mucosal dysplasia.
- Total colectomy with ileostomy is *curative*.
- Total proctocolectomy with ileal pouch anal anastomosis (IPAA) is the most common surgery and an appropriate alternative to ileostomy. Common complications include pouchitis (50%) and need for reoperation in up to 30% (2)[C].
- Regular proctoscopic surveillance is required if a colonic mucosal cuff is retained.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Insufficient evidence supports the efficacy of probiotics for maintaining remission (6)[A].
- Encouraging results in limited studies for aloe vera gel, wheat grass juice, *Andrographis paniculata* extract (HMPL-004), topical Xilei-san, curcumin, *Boswellia serrata* gum resin, *Plantago ovata* seeds, evening primrose oil, wormwood, and *Tripterygium wilfordii* (7)[A]
- Fecal microbiota transplant associated with nonsignificant increase in remission rate (8)[B].

## INPATIENT CONSIDERATIONS

### Admission Criteria/Initial Stabilization

- Obtain imaging studies to assess disease activity.
- Initiate IV corticosteroids and rule out infectious etiologies (*C. difficile*, cytomegalovirus, shigella/amoeba).

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

### Patient Monitoring

- Surveillance colonoscopy. Recommendations vary. Most begin a surveillance program after 8 years of disease with involvement beyond the splenic flexure with colonoscopy every 1 to 2 years including multiple random biopsies or targeted biopsies using chromoendoscopy.

- Initiate annual surveillance immediately in patients with primary sclerosing cholangitis.
- Magnification chromoendoscopy may detect significantly more intraepithelial neoplasias than conventional colonoscopy.
- Nonadenomatous dysplastic lesions or masses are associated with cancer in 33-83% of cases and warrant total colectomy.
- Annual LFTs and cholangiography for cholestasis
- Annual BUN/creatinine for patients on long-term mesalamine

### *Pediatric Considerations*

Cancer surveillance is important because cumulative risk of cancer increases with duration of disease.

### *DIET*

- NPO during acute exacerbations
- Lactose-free diet is often recommended.
- Omega-3 fatty acids, seal and cod liver oil, dietary lactulose, wheat grass juice, vitamin D, and diets with decreased meat and alcohol have been recommended to reduce relapses and improve systemic symptoms (inconsistent evidence) (7)[A].

### *PATIENT EDUCATION*

- Adherence to drug therapy is important to induce and maintain remission.
- Crohn and Colitis Foundation of America (CCFA): <http://www.ccfa.org/>

### *PROGNOSIS*

- Variable; mortality for initial attack is ~5%; 75-85% experience relapse; up to 20% require colectomy.
- Colon cancer risk is the single most important factor affecting long-term prognosis.
- Primary sclerosing cholangitis increases the risk of colon cancer in patients with ulcerative colitis.
- Left-sided colitis and ulcerative proctitis have favorable prognoses with probable normal lifespan.

### *Geriatric Considerations*

Increased mortality if first presentation occurs after 60 years of age.

- Consider lower medication dosages and slower titration due to risks of polypharmacy.

## COMPLICATIONS

Perforation (2-3% of hospitalized patients); obstruction; hemorrhage; fulminant colitis; toxic megacolon; liver disease; stricture formation (<Crohn disease); colon cancer

## See Also

&NA;

Algorithm: Hematemesis (Bleeding, Upper Gastrointestinal)

## Codes

&NA;

### ICD10

- K51.90 Ulcerative colitis, unspecified, without complications
- K51.919 Ulcerative colitis, unspecified with unspecified complications
- K51.80 Other ulcerative colitis without complications

## Clinical Pearls

&NA;

- UC always involves the colon and has continuous areas of inflammation with shallow mucosal ulcerations, and crypt granulomas are not seen on biopsy (differentiating features from Crohn colitis).
- Treat proctitis with 5-ASA suppositories.
- Colectomy is curative.
- Routine surveillance colonoscopy is recommended every 1 to 2 years after patients have had UC for 8 years.

# Upper Respiratory Infection (URI)

Lisa M. Schroeder, MD

Vu D. Tran, MD

## BASICS

Upper respiratory infections (URIs) are one of the most common medical diagnoses, contributing to ÷30 million office visits annually and resulting in significant lost productivity through missed days from work/school.

## DESCRIPTION

- Inflammation of nasal passages resulting from infection with multiple respiratory viruses
- Most cases are mild to moderate in severity, self-limited, and amenable to self-treat.
- System(s) affected: ENT; pulmonary

## EPIDEMIOLOGY

- Each virus has different seasonal peaks (e.g., rhinovirus: late spring, fall); most infections occur during the winter months.
- Symptoms usually peak in 1 to 3 days and can last up to 2 weeks.
- Transmission:
  - Contact with contaminated skin/surface followed by contact with mucous membranes (hand-to-face contact)
  - Aerosolized particles from sneezing and coughing
- Viruses may last up to 2 hours on skin and even longer on environmental surfaces.

## Incidence

- Predominant age: children > adults
  - Preschool children: 5 to 7 URI/year
  - Kindergarten: 12 URI/year
  - Schoolchildren: 7 URI/year

- Adolescents/adults: 2 to 3 URI/year
- Predominant sex: male = female

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Rhinoviruses infect the ciliated epithelial mucosa of the upper airway, resulting in edema, hyperemia, and mucous production.

- Histology: edema of subepithelial connective tissue and a scanty cellular infiltrate containing neutrophils, plasma cells, lymphocytes, and eosinophils with exudation of serous and mucinous fluid
- Rhinovirus causes a nondestructive inflammation of the mucous membranes.
- Influenza and parainfluenza viruses denude respiratory epithelium to the basement membrane.
- Several hundred viral strains from different families; spread within geographic region and groups with close contact
  - Rhinovirus (>100 serotypes): 30-50%; incubation period 1 to 5 days
  - Influenza virus types A, B, C: 10-15%; incubation period 1 to 4 days
  - Coronaviruses: 10-15%
  - Parainfluenza, respiratory syncytial virus (RSV): 5%; more common in children; incubation period 1 week
  - Enteroviruses, adenoviruses: <10%
- In many cases, no specific pathogen is identified.

## *RISK FACTORS*

- Exposure to infected people
- Touching one's face with contaminated fingers
- Allergic disorders
- Smoking
- Immunosuppression
- Stress

## *GENERAL PREVENTION*

- Frequent hand washing, especially in children (1,2)[A]

- Limiting exposure to infected persons/children
- Probiotic milk (with live culture lactobacillus) may reduce respiratory infections in children age <7 (3)[A].

## *COMMONLY ASSOCIATED CONDITIONS*

- Pharyngitis
- Sinusitis
- Otitis media
- Bronchitis
- Bronchiolitis
- Pneumonia
- Croup
- Asthma

## **DIAGNOSIS**

### **HISTORY**

- Nasal congestion: 80-100%
- Sneezing: 50-70%
- Throat irritation: 50%
- Cough: 40%
- Hoarseness: 30%
- Malaise: 20-25%
- Headache: 25%
- Fever >100°F (37.7°C): 0-1%

### *PHYSICAL EXAM*

- Low-grade temperature; mild tachycardia common with fever; tachypnea if significant respiratory involvement
- Rhinorrhea (clear, yellow, or green)
- Mucosal edema and/or inflammation
- Postnasal drainage

- Pharyngeal erythema
- Dull tympanic membranes

## ***DIFFERENTIAL DIAGNOSIS***

- Allergic rhinitis
- Acute sinusitis
- Strep pharyngitis
- Epiglottitis
- Infectious mononucleosis
- Pneumonia
- Influenza
- Pertussis
- Otitis media

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- No routine lab testing is typically needed, as diagnosis is based on clinical findings.
- In cases of pharyngitis, rapid streptococcal antigen testing with reflex culture can be used to rule out group A streptococcal infection if clinically suspected.
- Rapid influenza antigen testing if influenza is suspected.
- Heterophile antibody testing if infectious mononucleosis is suspected.
- Imaging not routinely indicated

### **Follow-Up Tests & Special Considerations**

Patients should consider contacting a physician's office for fever  $>101^{\circ}\text{F}$  associated with systemic symptoms, difficulty breathing, or purulent drainage  $>2$  days.

## **TREATMENT**

### ***GENERAL MEASURES***

- Smoking cessation

- Vaporizer/humidifier: no consistent benefit proven
- Cold preparations do not change course
- Antibiotics not indicated
- Avoid cough and cold preparations under age of 2 years.

## MEDICATION

Most cases of URI resolve spontaneously without specific intervention. Treatment is symptom-driven and for patient comfort.

### First Line

- Saline nasal irrigation is safe for adults and children.
- *Antibiotics are not recommended. They produce minimal to no reduction in symptoms or duration, with greater risk of side effects from usage (4)[A].*
- Analgesics: acetaminophen, and NSAIDs for relieving aches and pains associated with URI (5,6)[A]

### Second Line

- Many mouthwashes, gargles, and lozenges are promoted to relieve the pain of sore throat. The demulcent effects of hard candy, gargling with warm saline, and products with anesthetics (benzocaine/phenol) may provide pain relief.
- Aromatic oils (menthol, camphor, eucalyptus), produce a sensation of increased airflow without a significant change in airflow resistance.
- Topical decongestants (sympathomimetics) reduce nasal mucosa swelling and airflow resistance and promote drainage. Sprays preferred over drops in patients >6 years of age:
  - *Limit use to 3 days*, as rebound congestion may occur after 72 hours of use with resultant rhinitis medicamentosa.
    - Oxymetazoline
      - Adults and children aged 6 to 12 years: 0.05% solution, 2 to 3 sprays in each nostril BID

---

P.1081

- Oral decongestants (sympathomimetic) have some advantages over topical decongestants: longer duration of action, lack of local irritation, and no risk of rebound congestion (7)[B].
  - Pseudoephedrine: potential for abuse/misuse or diversion for methamphetamine production

- Use with caution for patients with cardiovascular disease, HTN, and BPH:
  - Adults: 60 mg q4-6h (120 mg sustainedrelease q12h) superior to placebo in short-term use (7)
  - Children aged 6 to 12 years: 30 mg q4 to 6h; 2 to 5 years: 15 mg q4 to 6h
- Acute cough, postnasal drip, and throat clearing associated with the common cold can be treated with a first-generation antihistamine/decongestant preparation (brompheniramine and sustainedrelease pseudoephedrine) (8)[A].
- Antihistamines: minimal benefit when used as monotherapy. Only first-generation (sedating) antihistamines show any symptomatic relief, but sedation may be worse than relief (9)[B]:
  - Chlorpheniramine
    - Adults: 4 mg QID, 8 mg TID, 12 mg BID
    - Children age 6 to 12 years: 2 mg q4-6h
  - Diphenhydramine
    - Adults: 25 to 50 mg q4-6h PRN
    - Children age 6 to 12 years 12.5 to 25 mg q4-6h PRN

### *Pediatric Considerations*

In 2007, the FDA issued a warning to limit the use of all cough and cold preparations for children age <sup>≥</sup>2 years due to risk of overdose (10,11)[A].

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Zinc prevents viral replication in vitro:
  - Avoid intranasal preparations of zinc: risk of potential permanent loss of smell (12)[C]
  - Has shown moderate benefit in reducing symptoms and duration, but proper dosing has not been determined
- Echinacea has not proven consistently effective for treatment of common cold symptoms (12) [C].
- Probiotics may decrease severity and duration of URIs and possibly reduce episodes (3,13)[B].
- Vitamin C (ascorbic acid) (14)[C]
  - Regular supplementation trials have shown that vitamin C may reduce the duration of colds.

- Vitamin C prophylaxis *not* recommended for general use but may be beneficial in those exposed to severe physical exertion and cold environments.

## *Geriatric Considerations*

Cold medications, especially decongestants and antihistamines, commonly produce adverse effects in older patients and should not be used routinely.

## *Pregnancy Considerations*

- Decongestants: Most are Category B or C.
- Antihistamines: Most are Category B or C.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Contact a physician's office for prolonged fever, difficulty breathing, or concern for secondary complications.

### *DIET*

Encourage fluids and adequate hydration.

### *PATIENT EDUCATION*

- Discuss the difference between viral and bacterial infections; instruct about appropriate antibiotic use.
- Good hand hygiene
- Symptomatic treatment; no cure
- Reinfection is possible with reexposure.
- Patient information: [www.niaid.nih.gov/factsheets/cold.htm](http://www.niaid.nih.gov/factsheets/cold.htm)

### *PROGNOSIS*

- Excellent; expect full recovery. Usual duration 5 to 7 days but may last up to 2 weeks. For smokers, 3 to 4 additional days
- Cough may persist after other symptoms have resolved.

### **COMPLICATIONS**

Small percentage may develop worsening symptoms leading to secondary otitis media, sinusitis, bronchitis, or pneumonia.

## Codes

&NA;

## ICD10

- J06.9 Acute upper respiratory infection, unspecified
- J11.1 Influenza due to unidentified influenza virus with other respiratory manifestations
- B97.4 Respiratory syncytial virus causing diseases classd elswhr

## Clinical Pearls

**&NA;**

- Supportive therapy is mainstay for most upper respiratory tract infections.
- Point of care testing can rule out group A *Streptococcus* infection in the appropriate clinical setting
- Limit unnecessary use of antibiotics.
- URI symptoms last 3 to 4 more days in smokers.

# Urethritis

Maria Harsha Wusu, MD, MEd

Joanne Wilkinson, MD, MSc

## BASICS

### DESCRIPTION

- Inflammation of the urethra
- Common manifestation of sexually transmitted infection
- Frequently associated with dysuria, pruritus, and/or urethral discharge; classified as gonococcal (caused by *Neisseria gonorrhoeae*) and nongonococcal (caused by other bacteria, or less commonly autoimmune disorders [Reiter syndrome], trauma, or chemical irritation)

### EPIDEMIOLOGY

#### Incidence

- In 2013, there were >330,000 reported cases of gonorrhea, with a rate of 106.1 cases per 100,000 population (0.6% decrease since 2012) (1)
- In 2013, there were >1.4 million reported cases of *Chlamydia trachomatis* infection, or 446.6 cases per 100,000 population (1.5% decrease since 2012) (2)
- Rate of chlamydial infection in U.S. women was more than twice that of men, reflecting higher rates of screening (1).
- Highest incidences of gonorrhea and chlamydia among young men and women, ages 15 to 24 years (1)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Most common cause is infection via sexual transmission of *N. gonorrhoeae*, a gram-negative diplococcus.
- *N. gonorrhoeae* interacts with nonciliated epithelial cells→ cellular invasion→ inflammation, neutrophil production, bacterial cell phagocytosis (2)
- Sexually transmitted *C. trachomatis* infection is the most common cause of nongonococcal urethritis.

- Other established pathogens
  - *Mycoplasma genitalium*
  - *Trichomonas vaginalis*
  - *Ureaplasma urealyticum*
  - Herpes simplex virus (rare)
  - Adenovirus (rare)
- Noninfectious causes (generally rare)
  - Chemical irritants (i.e., soaps, shampoos, douches, spermicides)
  - Foreign bodies
  - Urethral instrumentation

## **RISK FACTORS**

- One or more sex partner(s)
- New sex partner
- History of or coexisting STI
- Sex partner with concurrent partner(s)
- Inconsistent condom use outside of a mutually monogamous relationship
- Exchanging sex for money or drugs
- Member of population with increased prevalence of infection, including incarcerated populations, military recruits, black and Hispanic persons

## **GENERAL PREVENTION**

- Use of male condoms, female condoms, or cervical diaphragms
- Abstinence or reduction in the number of sex partners
- Behavioral counseling

## **COMMONLY ASSOCIATED CONDITIONS**

### **ALERT**

Annual chlamydia and gonorrhea screening is recommended for all sexually active women <25 years, women >25 years with risk factors, and all men who have sex with men (3).

## DIAGNOSIS

- Chief complaint
  - Urethral discharge (mucopurulent suggestive of *N. gonorrhoeae*)
  - Dysuria
  - Erythema of the urethral meatus
  - Symptom onset 2 to 8 days following exposure
- History
  - Sexual history, including condom use, number of partners, sexual behaviors
  - Previous STIs
  - Substance abuse
  - Recent travel
  - Symptoms indicative of complications or additional sites of infection (i.e., men: testicular pain and swelling, anal itching, rectal pain or bleeding; women: lower abdominal pain, dyspareunia, irregular vaginal bleeding)
- Male GU exam (possible findings)
  - Urethral discharge
  - Meatal erythema
  - Testicular tenderness
  - Palpate scrotum to check for epididymitis or orchitis.
  - Check for ulcers.
  - Check for inguinal lymphadenopathy.
- Female GU exam (possible findings)
  - Vaginal discharge
  - Endocervical discharge, hyperemia, and/or friability

### *Pediatric Considerations*

Pediatric infections with gonorrhea and chlamydia after the neonatal period strongly suggest sexual contact. If indicated, investigations should be initiated promptly (3).

# DIFFERENTIAL DIAGNOSIS

- Other genitourinary tract diseases
  - Cystitis/urinary tract infection
  - Epididymitis
  - Prostatitis
  - PID
  - Pyelonephritis
- Vaginal atrophy, especially in postmenopausal women
- Stevens-Johnson syndrome
- Reiter syndrome: uveitis, urethritis, arthritis
- Wegener granulomatosis

## DIAGNOSTIC TESTS & INTERPRETATION

### **ALERT**

Health care providers are required to report all gonorrhea and chlamydia infections in accordance with local and state requirements.

### *Initial Tests (lab, imaging)*

- Gram-stain diagnosis of urethritis if: urethral secretions with  $\geq 2$  WBC per oil immersion field, mucopurulent or purulent discharge, or first void urine sediment with  $\geq 10$  WBC per high-power field (hpf) (3)
- Gonorrhea
  - Nucleic acid amplification test (NAAT): in men: first void urine preferred (90-100% sensitivity, 97-100% specificity for gonorrhea); in women: vaginal swab preferred (patient or clinician collected), end cervical swab acceptable, first void urine may detect 10% fewer infections (3) [A]
  - Culture: traditional gold standard—most commonly used in cases of suspected treatment resistance (3)
- Chlamydia
  - NAAT: in men: first catch urine equal to urethral swab (85-95% sensitivity, 93-99% specificity); in women: vaginal swab preferred (patient or clinician collected), end cervical swab acceptable, first void urine may detect 10% fewer infections (3)[A]

- Tissue cultures: traditional gold standard, but currently NOT recommended (3)
- If concern for trichomonas: NAAT (urine, urethral, vaginal, or endocervical swab), wet mount, or culture
- There is no FDA-approved diagnostic test available for *M. genitalium*.

## **ALERT**

Due to the similarity in clinical symptoms and high rates of coinfection, cotesting for gonorrhea and chlamydia infection is recommended. In addition, given that risk factors for gonorrhea and chlamydia indicate risks for other STIs, screening for HIV, RPR, Hepatitis C, and Hepatitis B may also be indicated.

## **Follow-Up Tests & Special Considerations**

- Test of cure for chlamydia and gonorrhea is recommended in pregnant women or when treatment noncompliance is suspected (3).
- Repeat testing in 3 months recommended due to rates of reinfection (3)
- HIV infection: Persons with HIV infection should receive the same treatment as patients without HIV infection (3).

## *Diagnostic Procedures/Other*

Urethrocystoscopy for cases with suspected foreign body, intraurethral warts, urethral stricture

## *Test Interpretation*

Urethral strictures (untreated gonorrhea), intraurethral lesions (venereal warts, congenital anomalies), PID, or tubo-ovarian abscesses are possible.

P.1083

## **TREATMENT**

### **GENERAL MEASURES**

- Most cases can be treated in the outpatient setting.
- Single-dose regimens with direct observation preferred (3)

### **MEDICATION**

#### *First Line*

- Gonorrhea

- Ceftriaxone 250 mg IM plus either: azithromycin 1 g PO × 1 dose (preferred) *OR* doxycycline 100 mg PO BID for 7 days (if azithromycin allergy) (3)[A]
- For children <sup>2</sup>45 kg: ceftriaxone 25 to 50 mg/kg (max 125 mg) IM × 1 dose. For children >45 kg: use adult dosing.
- Chlamydia
  - Azithromycin: 1 g PO × 1 dose *OR*
  - Doxycycline: 100 mg PO BID for 7 days (3)[A]
  - Alternative regimens (all for 7 days): erythromycin base 500 mg PO QID, erythromycin ethylsuccinate 800 mg PO QID, levofloxacin 500 mg daily, *OR* ofloxacin 300 mg PO BID
- Trichomonas
  - Metronidazole: 2 g PO × 1 dose
- Recurrent and resistant urethritis
  - Metronidazole: 2 mg PO single dose *OR* tinidazole 2 g PO single dose plus azithromycin 1 g PO × 1 dose
- Contraindications: sensitivity to any of the indicated medications
- Precautions: Patients taking tetracyclines may have increased photosensitivity.
- Significant possible interactions
  - Tetracyclines should not be taken with milk products or antacids.
  - Oral contraceptives may be rendered less effective by oral antibiotics. Patients and partners should use a back-up method of birth control for the remainder of the cycle.

## *Pregnancy Considerations*

- Chlamydia: All pregnant women <25 years and older women at increased risk should be screened for chlamydia at their first prenatal visit and again in the 3rd trimester. Women with chlamydia infections should be treated, have a documented TOC 3 to 4 weeks after treatment, and retested in 3 months (3).
- Gonorrhea: All pregnant women under <25 years and older women at increased risk should be screened for gonorrhea at their first prenatal visit and again in the third trimester. Women with gonorrhea infections should be treated and be retested in 3 months (3).
- Tetracyclines and quinolones are contraindicated.
- Avoid erythromycin estolate because of an increased risk of cholestatic jaundice.

- Single-dose therapy is recommended.

## *Second Line*

- Gonorrhea: If ceftriaxone is not an option, cefixime 400 mg PO × 1 dose plus either: azithromycin 1 g PO × 1 dose OR doxycycline 100 mg PO BID for 7 days (if azithromycin allergy); followed by a TOC in 1 week (3).
- Chlamydia alternative regimens (all for 7 days): erythromycin base 500 mg PO QID, erythromycin ethylsuccinate 800 mg PO QID, levofloxacin 500 mg daily, OR ofloxacin 300 mg PO BID (3)

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Sexual activity should be avoided for 7 days following administration of single-dose therapy or until completion of multiday regimen.
- All sexual partners who came in contact with the patient within 60 days should be referred for evaluation, testing, and presumptive treatment (3).
- Expedited partner therapy (EPT) is an acceptable alternative. EPT is the practice of treating the diagnosed patient's sex partner(s) for chlamydia or gonorrhea by providing medications or prescriptions to the patient to provide to the partner(s) without clinical evaluation (3).

### *Patient Monitoring*

- Instruct patients to return if symptoms persist or recur after completing treatment.
- Test of cure in 3 to 4 weeks in pregnant women suspected of nonadherence, reinfection, persistent symptoms
- Screen for reinfection in all patients at 3 months.

### *DIET*

Avoid alcohol when taking metronidazole.

### *PATIENT EDUCATION*

- Behavioral counseling interventions are recommended. Evidence of benefit increase with intensity of intervention (4).
- Successful approaches include basic information about STIs and transmission, assess risk for transmission, include training skills (i.e., condom use, communication about safe sex, problem

solving, goal setting) (4).

## PROGNOSIS

If the diagnosis is firmly established, appropriate medications are prescribed and the patient is compliant with treatment; relief of symptoms occurs within days and the problem will resolve without sequel.

## COMPLICATIONS

- Stricture formation
- Epididymitis
- Prostatitis
- PID in women
- Disseminated gonococcal infection
- Gonococcal meningitis
- Gonococcal endocarditis
- Perinatal transmission (chlamydial conjunctivitis, chlamydial pneumonia, ophthalmia neonatorum)
- Reiter syndrome

- A54.01 Gonococcal cystitis and urethritis, unspecified

## Clinical Pearls

**&NA;**

- Inflammation of the urethra, frequently associated with dysuria, pruritus, and/or urethral discharge
- Common manifestation of STI
- Classified as gonococcal (caused by *N. gonorrhoeae*) and nongonococcal
- Nucleic acid amplification test (NAAT) preferred method of diagnosis for men and women
- Single-dose regimens with direct observation preferred
- In cases of gonorrhea or chlamydia infection, in person or expedited partner therapy (EPT) recommended for all partners of patients within the last 60 days
- Given that risk factors for gonorrhea and chlamydia indicate risk for other STIs, screening for

HIV, RPR, Hepatitis C, and Hepatitis B may also be indicated.

- Repeat testing for gonorrhea and chlamydia in 3 months recommended due to rates of reinfection.
- Special considerations in pediatric and pregnant populations
- Treatment in persons with HIV infection is the same as in patients without HIV infection.
- Health care providers are required to report all gonorrhea and chlamydia infections in accordance with local and state requirements.

# Urinary Tract Infection (UTI) in Females

Akhil Das, MD, FACS

## BASICS

### DESCRIPTION

- Urinary tract infection (UTI) is the presence of pathogenic microorganisms within the urinary tract with concomitant symptoms.
- This topic refers primarily to infectious cystitis; other complicated UTIs, such as pyelonephritis, are discussed elsewhere.
- Uncomplicated UTI: occurs in patients who have a normal, unobstructed urinary tract, who have no history of recent instrumentation, and whose symptoms are confined to the lower urinary tract. Uncomplicated UTIs are most common in young, sexually active women.
- Complicated UTI: an infection of the lower or upper urinary tract in the presence of an anatomic abnormality, a functional abnormality, or a urinary catheter
- Recurrent UTI: symptomatic UTIs that follow resolution of an earlier episode, usually after appropriate treatment
  - No single definition of the frequency of recurrent UTI exists, but a pragmatic definition is <sup>33</sup> infections per year.
  - Most recurrences are thought to represent reinfection rather than relapse.
  - No evidence indicates that recurrent UTIs lead to health problems such as hypertension or renal disease in the absence of anatomic or functional abnormalities of the urinary tract (1) [A].
- System(s) affected: renal/urologic
- Synonym(s): cystitis; infectious cystitis

### EPIDEMIOLOGY

#### Incidence

- Accounts for 8 million doctor visits and 1 million emergency room visits, and contributes to >100,000 hospital admissions each year

- 11% of women have UTIs in any given year.
- Predominant age: young adults and older
- Predominant sex: female > male

## *Prevalence*

- >50% of females have at least one UTI in their lifetime.
- One in four women have recurrent UTIs.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Bacteria and subsequent infection in the urinary tract arise chiefly via ascending bacterial movement and propagation (1).
- Pathogenic organisms (*Escherichia coli*) possess adherence factors and toxins that allow initiation and propagation of genitourinary infections:
  - Type 1 and *P. pili* (*pyelonephritis-associated pili*)
  - Lipopolysaccharide
- Most UTIs are caused by bacteria originating from bowel flora:
  - *E. coli* is the causative organism in 80% of cases of uncomplicated cystitis.
  - *Staphylococcus saprophyticus* accounts for 15% of infections.
  - Enterobacteriaceae (i.e., *Klebsiella*, *Proteus*, *Enterobacter*, and *Pseudomonas*) also contribute.
- *Candida* is associated with nosocomial UTI (2).

## *Genetics*

Women with human leukocyte antigen 3 (HLA-3) and nonsecretor Lewis antigen have an increased bacterial adherence, which may lead to an increased risk in UTI.

## *RISK FACTORS*

- Previous UTI
- Diabetes mellitus (DM)
- Pregnancy
- Sexual activity
- Use of spermicides or diaphragm

- Underlying abnormalities of the urinary tract such as tumors, calculi, strictures, incomplete bladder emptying, urinary incontinence, neurogenic bladder
- Catheterization
- Recent antibiotic use
- Poor hygiene
- Estrogen deficiency
- Inadequate fluid intake

## GENERAL PREVENTION

- Maintain good hydration.
- Women with frequent or intercourse-related UTI should empty bladder immediately before and following intercourse; consider postcoital antibiotic.
- Avoid feminine hygiene sprays and douches.
- Wipe urethra from front to back.
- Cranberry juice (not cranberry juice cocktail) consumption may prevent recurrent infections.

## COMMONLY ASSOCIATED CONDITIONS

See ÒRisk Factors.Ó

### *Geriatric Considerations*

- Elderly patients are more likely to have underlying urinary tract abnormality.
- Acute UTI may be associated with incontinence or mental status changes in the elderly.

## DIAGNOSIS

### HISTORY

Note: Any or all may be present:

- Burning during urination
- Pain during urination (dysuria)
- Urgency (sensation of need to urinate often)
- Frequency
- Sensation of incomplete bladder emptying

- Blood in urine
- Lower abdominal pain or cramping
- Offensive odor of urine
- Nocturia
- Sudden onset of urinary incontinence
- Dyspareunia

## *PHYSICAL EXAM*

- Suprapubic tenderness
- Urethral and/or vaginal tenderness
- Fever or costovertebral angle tenderness indicates upper UTI.

## *DIFFERENTIAL DIAGNOSIS*

- Vaginitis
- Asymptomatic bacteriuria
- STDs causing urethritis or pyuria
- Hematuria from causes other than infection (e.g., neoplasia, calculi)
- Interstitial cystitis
- Psychological dysfunction

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- No lab testing is necessary in women with high likelihood of lower UTI based on classic symptoms.
- Urinalysis
  - Pyuria (>10 neutrophils/high-power field [HPF])
  - Bacteriuria (any amount on unspun urine, or 10 bacteria/HPF on centrifuged urine)
  - Hematuria (>5 RBCs/HPF)
- Dipstick urinalysis
  - Leukocyte esterase (75-96% sensitivity, 94-98% specificity, when >100,000 colonyforming units [CFU])

- Nitrite tests are useful with nitrite-reducing organisms (e.g., enterococci, *S. saprophyticus*, *Acinetobacter*).
- Urine culture: *only* indicated if diagnosis is unclear or patient has recurrent infections and resistance is suspected. It is neither cost-effective nor usually helpful for lower-tract, uncomplicated UTI.
  - Presence of 100,000 CFU/mL of organism indicates infection.
  - Identification of a single organism at lower CFU per milliliter likely also represents infection in the presence of appropriate symptoms.
  - Suspect a contaminated specimen when culture shows multiple types of bacteria.
- Imaging studies are often not required in most cases of UTI.

## Follow-Up Tests & Special Considerations

- In nonpregnant, premenopausal women with symptoms of UTI, positive urinalysis, and no risks for complicated infection, empirical treatment may be given without obtaining a urine culture.
- Dipstick urinalysis may be helpful but not necessary in patients with characteristic symptoms (i.e., high pretest probability).
- Imaging may be indicated for UTIs in men, infants, immunocompromised patients, febrile infection, signs or symptoms of obstruction, failure to respond to appropriate therapy, and in patients with recurrent infections.
- CT scan and MRI provide the most complete anatomic data in adults.

## *Pediatric Considerations*

For infants and children, obtain US; if ureteral dilatation is detected, obtain either voiding cystourethrogram or isotope cystogram to evaluate for reflux.

## *Diagnostic Procedures/Other*

- Urethral catheterization maybe necessary to obtain a urine specimen from children and adults if the voided urine is suspected of being contaminated.
- Suprapubic bladder aspiration or urethral catheterization techniques can be used to obtain specimens from infants.
- Cystourethroscopy can be used for patients with recurrent UTIs and previous anti-incontinence surgery or hematuria (3)[A].

## TREATMENT

### GENERAL MEASURES

- Maintain good hydration.
- Maintain good hygiene.
- 1/4 of women with uncomplicated UTI experience a second UTI within 6 months and 1/2 at some time during their lifetime.

P.1085

### MEDICATION

#### First Line

- The urinary tract topical analgesic phenazopyridine 100 to 200 mg TID produces rapid relief of symptoms and should be offered to patients with more than minor discomfort; it is available over the counter. This medication is not a substitute for definitive treatment. This medication also may alter urinalysis but not the urine culture.
- Uncomplicated UTI (adolescents and adults who are nonpregnant, nondiabetic, afebrile, immunocompetent, and without genitourinary anatomic abnormalities)
  - Trimethoprim-sulfamethoxazole (TMP-SMZ; Bactrim): 160/800 mg PO BID for 3 days, best where resistance of *E. coli* strains <20%
  - 5-day course of nitrofurantoin or 3-day fluoroquinolone course should be used in patients with allergy to TMP-SMZ and in areas where *E. coli* resistance to TMP-SMZ >20% (3)[A].
  - Fosfomycin (Monurol): 3 g PO single dose (expensive)
- Lower UTI in pregnancy
  - Nitrofurantoin (Macrobid): 100 mg PO BID for 7 days
  - Cephalexin (Keflex): 500 mg PO BID for 7 days
- Postcoital UTI: single-dose TMP-SMX or cephalexin may reduce frequency of UTI in sexually active women.
- Complicated UTI (pregnancy, diabetes, febrile, immunocompromised patient, recurrent UTIs): Extend course to 7 to 10 days of treatment with antibiotic chosen based on culture results; may begin with fluoroquinolone, TMP-SMX, or cephalosporin while awaiting results (avoid using nitrofurantoin for complicated UTI)
  - Fluoroquinolones are not safe during pregnancy and are usually avoided in treatment of

children.

- TMP-SMX use in pregnancy is not desirable (especially in 3rd trimester) but is appropriate in some circumstances (3)[A].

## *Second Line*

- Uncomplicated UTI
  - Ciprofloxacin: 250 mg PO BID for 3 days; should be reserved for complicated UTIs
  - *&bgr*;-Lactams (amoxicillin/clavulanate, cefdinir, cefpodoxime proxetil) for 3 to 7 days
- Chronic UTIs
  - Women with recurrent symptomatic UTIs can be treated with continuous or postcoital prophylactic antibiotics. Treatment duration guided by the severity of patient symptoms and by physician and patient preference: Consider 6 months of therapy, followed by observation for reinfection after discontinuing prophylaxis.
    - Continuous antimicrobial prophylaxis involves daily administration of low-dose TMP-SMX 40/200 mg or nitrofurantoin 50 to 100 mg, among others.
- Another treatment option is self-started antibiotics.

## *Pediatric Considerations*

Long-term antibiotics appear to reduce the risk of recurrent symptomatic UTI in susceptible children, but the benefit is small and must be considered together with the increased risk of microbial resistance.

## *ISSUES FOR REFERRAL*

Men with uncomplicated UTI and most other patients with complicated UTI should be referred to a urologist for evaluation.

## *Pediatric Considerations*

UTI in children, especially <1 year of age, should prompt workup for urinary tract anomalies.

## *SURGERY/OTHER PROCEDURES*

- Urinary tract obstruction with urosepsis requires urgent drainage of the obstructed system.
- Patients with emphysematous pyelonephritis or pyonephrosis may need immediate surgical intervention.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Preliminary studies indicate that *Vaccinium macrocarpon* (cranberry) juice may help to prevent and treat UTIs by inhibiting bacterial adherence to the bladder epithelium.
- Cranberry juice may decrease the number of symptomatic UTIs over a 1-year period, particularly for women with recurrent UTIs. The optimal dosage or method of administration (e.g., juice, tablets, or capsules) is still unclear.

## INPATIENT CONSIDERATIONS

Inpatient evaluation is reserved for patients with complicated or upper tract UTIs. Majority of UTIs are managed in an outpatient setting.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

- First or rare UTI: Young or middle-aged, nonpregnant adult females require no follow up if UTI is clinically cured after 3-day therapy.
- If symptoms persist after 2 to 3 days of therapy, obtain culture/sensitivity and change antibiotic accordingly.

### Pregnancy Considerations

- UTI during pregnancy always requires culture/sensitivity and usually requires a 7- to 14-day treatment.
- Following the treatment of acute infection, pregnant women warrant surveillance urine cultures every trimester. They may receive prophylactic antibiotics for the remainder of pregnancy for recurrent or upper tract disease.

## PATIENT EDUCATION

- Although no controlled studies support this intervention, postcoital voiding is commonly advised.
- FamilyDoctor Web site: <http://familydoctor.org/familydoctor/en/diseases-conditions/urinary-tractinfections.html>

## PROGNOSIS

Symptoms resolve within 2 to 3 days of antibiotic treatment in almost all patients.

## COMPLICATIONS

- Pyelonephritis or sepsis
- Renal abscess
- Acute urinary outlet obstruction

### ***Pregnancy Considerations***

Pregnant females, infants, and young children with cystitis are at higher risk of pyelonephritis.

## See Also

**&NA;**

Algorithm: Dysuria

## Codes

**&NA;**

### ICD10

- N39.0 Urinary tract infection, site not specified
- N30.90 Cystitis, unspecified without hematuria
- N30.91 Cystitis, unspecified with hematuria

## Clinical Pearls

**&NA;**

- Uncomplicated UTIs cause significant morbidity but generally do not cause renal damage.
- Treatment of uncomplicated UTIs reduces morbidity, but the risk of recurrence stays the same.
- Bacteria originating from intestinal tract cause most UTIs, especially *E. coli*.
- Imaging studies are not required for most women with UTIs.
- Uncomplicated UTIs should be treated for 3 days (TMP-SMX) or 5 days (nitrofurantoin). All pregnant women with bacteriuria should be treated.

# Urinary Tract Infection (UTI) in Males

Amy L. Wisner, MD

## BASICS

### DESCRIPTION

- Cystitis is an infection of the lower urinary tract, usually resulting from a single gram-negative enteric bacteria. (See also Prostatitis, Pyelonephritis, and Urethritis.)
- System(s) affected: renal/urologic
- Synonym(s): urinary tract infection (UTI); cystitis
- Conventional consideration of UTI in male newborn, infant, and elderly men is complicated, with associated functional/structural mechanisms.
- In otherwise healthy males ages 15 to 50 years, UTI is uncommon and considered uncomplicated.

### EPIDEMIOLOGY

#### Incidence

- Approximately 20% of UTIs occur in men (1).
- Predominant age: increases with age
- Uncommon in men <50 years of age
- 6 to 8 infections/10,000 men aged 21 to 50 years (2)

#### Prevalence

Lifetime prevalence approximately 14% (1)

### ETIOLOGY

- *Escherichia coli* (majority of infections)
- *Klebsiella*
- *Enterobacter*

## *Enterococcus*

- *Proteus*
- *Serratia*
- *Citrobacter*
- *Providencia*
- *Streptococcus faecalis* and *Staphylococcus* sp.
- *Pseudomonas* and *Morganella* (more common in elderly and catheterized patients)
- Pathogenesis—bacterial entry into urinary tract via ascension or bladder instrumentation

## *Genetics*

Not applicable

## **RISK FACTORS**

- Age
- Obesity (3)
- History of prior UTI
- Outlet obstruction
  - Benign prostatic hypertrophy (BPH)—incidence of 33% of men with UTIs (4)
  - Urethral stricture
  - Calculi
- Cognitive impairment
- Fecal incontinence
- Urinary incontinence
- Anal intercourse
- Recent urologic surgery
- Infection of the prostate/kidney
- Urinary tract instrumentation, catheterization
- Immunocompromised host
- Diabetes
- Bladder diverticula

- Neurogenic bladder
- Institutionalization
- Uncircumcised
- Engaging in sex with an infected female partner (2)

## **GENERAL PREVENTION**

- Prompt treatment of predisposing factors
- Use a catheter only when necessary; if needed, use aseptic technique and closed system and remove as soon as possible.
- Currently, cranberry products are not recommended for preventing UTIs in men (5).

## **COMMONLY ASSOCIATED CONDITIONS**

- Acute bacterial pyelonephritis
- Chronic bacterial pyelonephritis
- Urethritis
- Prostatitis
- Prostatic hypertrophy
- Prostate cancer

### *Geriatric Considerations*

Bacteriuria is common among the elderly; may be related to functional status and usually is transient. Of men older than 65 years of age, 5-10% have asymptomatic bacteriuria (ASB). If ASB is noted, no treatment is needed (6,7).

### *Pediatric Considerations*

Can be associated with obstruction to normal flow of urine, such as vesicoureteral reflux. Unique diagnostic criteria and evaluation recommendations exist (see below) (8).

## **DIAGNOSIS**

### **HISTORY**

- Urinary frequency
- Urinary urgency

- Dysuria
- Hesitancy
- Slow urinary stream
- Dribbling of urine
- Nocturia
- Suprapubic discomfort or perineal pain
- Low back pain
- Hematuria
- Systemic symptoms (chills, fever) or flank pain, nausea, vomiting present with concomitant pyelonephritis or prostatitis (9).

## *PHYSICAL EXAM*

- Suprapubic tenderness
- Costovertebral angle (CVA) tenderness and/or fever may be present with concomitant pyelonephritis/prostatitis/epididymitis.

## *DIFFERENTIAL DIAGNOSIS*

- Anatomic/functional pathology of the urinary tract
- Urethritis/STIs
- Infections in other sites of the genitourinary tract (e.g., epididymis, prostatitis). More than 90% of men with febrile UTI have concomitant prostate infection (9).

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Urine dipstick/manual microscopy of clean catch midstream void showing the following:
  - Pyuria (>10 WBCs)
  - Bacteriuria
  - Positive leukocyte esterase (in males: sensitivity, 78%; specificity, 59%; positive predictive value [PPV], 71%; negative predictive value [NPV], 67%)
  - Positive nitrite (in males: sensitivity, 47%; specificity, 98%; PPV, 96%; NPV, 59%)
  - In general, leukocyte esterase is more sensitive and nitrite is more specific in detecting UTI (10).
- Automated microscopy/flow cytometry that measures cell counts and bacterial counts can be used to improve screening characteristics (sensitivity, 92%; specificity, 55%; PPV, 47%; NPV,

97%). The high NPV of these screening tests allows for more judicious use of urine culture (11).

- Urine culture: > 100,000 colony-forming units (CFU; >10<sup>5</sup> CFU) of bacteria/mL of urine confirm diagnosis.
- Lower counts, such as >10<sup>3</sup> CFU, also may be indicative of infection, especially in the presence of pyuria.
- Diagnosis in infants and children <24 months made on the basis of both pyuria and 50,000 CFU on culture.
- Renal and bladder ultrasound recommended in infants and young children after first confirmed UTI.

## Follow-Up Tests & Special Considerations

- Consider assessing for risk factors for STIs, as chlamydial/gonococcal urethritis can mimic a UTI. If risk factors are present, use urine nucleic acid amplification tests to identify gonococcal and *Chlamydia* infections and treat as necessary.
- Further urologic evaluation is warranted to rule out other disorders in men with recurrent UTI, febrile UTI, or pyelonephritis. This may include the following:
  - Ultrasound
  - Cystoscopy
  - Urodynamics
  - IV pyelography
- Value of a urologic evaluation in a single uncomplicated UTI has not been determined (9).
- Antibiotics prior to culture or phenazopyridine prior to urine dipstick can alter results.

## Test Interpretation

Depends on site of infection

---

P.1087

## TREATMENT

### GENERAL MEASURES

- Hydration

- Analgesia, if required
- Patient with indwelling catheters
  - If asymptomatic bacterial colonization, no need to treat (sterilization of urine is not possible, and resistant organisms may take up residence).
  - If symptomatic of acute infection, institute treatment.

## *MEDICATION*

### *First Line*

- Acute, uncomplicated cystitis
  - Treat empirically; strongly consider if nitrite positive, using local resistance patterns or based on culture and sensitivity results for 7 days (9)[B]. For empirical therapy, a fluoroquinolone or trimethoprim-sulfamethoxazole DS usually used to treat the most likely pathogens (9).
- Complicated, febrile, or recurrent infection
  - Prescribe a minimum of 2 weeks antibiotics based on antimicrobial sensitivities with repeat urine check after the treatment. In men with febrile UTI or pyelonephritis, prostatic involvement also has to be considered. Treatment of concomitant prostatitis requires antimicrobials with good prostatic tissue and fluid penetration (fluoroquinolones) (9)[B].

### *Second Line*

According to culture and sensitivity results and patient's history

## *ISSUES FOR REFERRAL*

Further urologic evaluation and referral are warranted to rule out other disorders in men with recurrent UTI, febrile UTI, or pyelonephritis.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Inability to tolerate oral medications
- Acute renal failure
- Suspected sepsis

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

Close follow-up until clinically well

#### *DIET*

Encourage adequate fluid intake.

### PATIENT EDUCATION

For patient education materials about this topic that have been reviewed favorably, contact the National Kidney Foundation, 30 E. 33rd Street, Suite 1100, New York, NY 10016; 212-889-2210.

### PROGNOSIS

Clearing of infections with appropriate antibiotic treatment

### COMPLICATIONS

- Pyelonephritis
- Ascending infection
- Recurrent infection
- Prostatitis

## Codes

**&NA;**

### ICD10

- N39.0 Urinary tract infection, site not specified
- N30.90 Cystitis, unspecified without hematuria
- N30.91 Cystitis, unspecified with hematuria

## Clinical Pearls

**&NA;**

- Cystitis is an infection of the lower urinary tract, usually resulting from a single gram-negative enteric bacteria.
- Risk factors/causes: age, history of UTI, obesity, BPH, cognitive impairment, fecal incontinence, urinary incontinence, anal intercourse, recent urologic surgery, catheterization, infection of the prostate/kidney, urinary tract instrumentation, immunocompromised host, diabetes, neurogenic bladder, outlet obstruction, sex with infected female partner
- Evaluation: urinalysis, urine culture, STI testing (e.g., gonorrhea, *Chlamydia* by culture/DNA probe)
- Treat empirically with fluoroquinolones or trimethoprim-sulfamethoxazole DS for 7 days.

# Urolithiasis

Phillip Fournier, MD

## BASICS

### DESCRIPTION

- Stone formation within the urinary tract: Urinary crystals bind to form a nidus which grows to form a calculus (stone).
- Range of symptoms: asymptomatic to obstructive; febrile morbidity if result of infection

### EPIDEMIOLOGY

- The worldwide epidemiology differs according to both geographic area (higher prevalence in hot, arid, or dry climates) and socioeconomic conditions (dietary intake and lifestyle). Radiolucent stones and stones secondary to infection are less influenced by environmental conditions.
- Vesical calculosis (bladder stones) due to malnutrition during early life is frequent in Middle East and Asian countries.
- Incidence in industrialized countries seems to be increasing, probably due to improved diagnostics as well as to increasingly rich diets.
- Increased incidence in patients with surgically induced absorption issues, such as Crohn disease and gastric bypass surgery (1)[B]

### Incidence

- In industrialized countries: 100 to 200/100,000/year (2)
- Predominant age: Mean age is 40 to 60 years.
- Predominant sex: male > female (÷2:1) (3)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Supersaturation and dehydration lead to high salt content in urine which congregates.
- Stasis of urine
  - Renal malformation (e.g., horseshoe kidney, ureteropelvic junction obstruction)

- Incomplete bladder emptying (e.g., neurogenic bladder, prostate enlargement, multiple sclerosis)
- Crystals may form in pure solutions (homogeneous) or on existing surfaces, such as other crystals or cellular debris (heterogeneous).
- Balance of promoters and inhibitors: organic (Tamm-Horsfall protein, glycosaminoglycan, uropontin, nephrocalcin) and inorganic (citrate, pyrophosphate)
- Calcium oxalate and/or phosphate stones (80%)
  - Hypercalciuria
    - Absorptive hypercalciuria: increased jejunal calcium absorption
    - Renal leak: increased calcium excretion from renal proximal tubule
    - Resorptive hypercalciuria: mild hyperparathyroidism
  - Hypercalcemia
    - Hyperparathyroidism
    - Sarcoidosis
    - Malignancy
    - Immobilization
    - Paget disease
- Hyperoxaluria
  - Enteric hyperoxaluria
    - Intestinal malabsorptive state associated with irritable bowel disease, celiac sprue, or intestinal resection
    - Bile salt malabsorption leads to formation of calcium soaps.
  - Primary hyperoxaluria: autosomal recessive, types I and II
  - Dietary hyperoxaluria: overindulgence in oxalaterich food
- Hyperuricosuria
  - Seen in 10% of calcium stone formers
  - Caused by increased dietary purine intake, systemic acidosis, myeloproliferative diseases, gout, chemotherapy, Lesch-Nyhan syndrome

Thiazides, probenecid

- Hypocitraturia
  - Caused by acidosis: renal tubular acidosis, malabsorption, thiazides, enalapril, excessive dietary protein
- Uric acid stones (10-15%): hyperuricemia causes as discussed earlier
- Struvite stones (5-10%): infected urine with ureaseproducing organisms (most commonly *Proteus* sp.)
- Cystine stones (<1%): autosomal recessive disorder of renal tubular reabsorption of cystine
- Bladder stones: seen with chronic bladder catheterization and some medications (indinavir)
- In children: usually due to malnutrition

## Genetics

- Up to 20% of patients have a family history. However, spouses of those who form stones have higher calcium excretion rates than controls, suggesting strong dietary-environmental factors.
- Autosomal dominant: idiopathic hypercalciuria
- Autosomal recessive
  - Cystinuria, Lesch-Nyhan syndrome, hyperoxaluria types I and II
  - Ehlers-Danlos syndrome, Marfan syndrome, Wilson disease, familial renal tubular acidosis

## RISK FACTORS

- White > African American in regions with both populations
- Family history
- Previous history of nephrolithiasis
- Diet rich in protein, refined carbohydrates, and sodium, carbonated drinks
- Occupations associated with a sedentary lifestyle or with a hot, dry workplace
- Incidence rates peak during summer secondary to dehydration.
- Obesity
- Surgically/medically induced malabsorption (Crohn disease, gastric bypass, celiac)

## GENERAL PREVENTION

Hydration (4)[A]

- Decrease salt and meat intake
- Avoid oxalate-rich foods.

## *Pediatric Considerations*

Rare: more common in men with low socioeconomic status

## *Pregnancy Considerations*

- Pregnant women have the same incidence of renal colic as do nonpregnant women.
- Most symptomatic stones occur during the 2nd and 3rd trimesters, heralded by symptoms of flank pain/hematuria.
- Most common differential diagnosis is physiologic hydronephrosis of pregnancy. Use ultrasound to avoid irradiation. Noncontrast-enhanced CT scan also is diagnostic.
- Treatment goals
  - Control pain and avoid infection, and preserve renal function until birth or stone passage.
  - 30% require intervention, such as stent placement.

## **DIAGNOSIS**

### **HISTORY**

- Pain
  - Renal colic: acute onset of severe groin and/or flank pain
  - Distal stones may present with referred pain in labia, penile meatus, or testis.
- Microscopic/gross hematuria occurs in 95% of patients.
- Nonspecific symptoms of nausea, vomiting, tachycardia, diaphoresis
- Low-grade fever without signs of infection
- Infectious origin: associated with high-grade fevers require more urgent treatment (see the following text)
- Frequency and dysuria especially occur with stones at the vesicoureteric junction (VUJ).
- Asymptomatic: nonobstructing stones within the renal calyces

## PHYSICAL EXAM

Tender costovertebral angle with palpation/percussion and/or iliac fossa

## DIFFERENTIAL DIAGNOSIS

- Appendicitis
- Ruptured aortic aneurysm
- Musculoskeletal strain
- Pyelonephritis (upper UTI)
- Pyonephrosis (obstructed upper UTI; emergency)
- Perinephric abscess
- Ectopic pregnancy
- Salpingitis

## DIAGNOSTIC TESTS & INTERPRETATION

- Urinalysis for RBCs, leukocytes, nitrates, pH (acidic urine <5.5 is associated with uric acid stones; alkaline >7 with struvite stones)
- Midstream urine for microscopy, culture, and sensitivity
- Blood: urea, creatinine, electrolytes, calcium, and urate; consider CBC.
- Parathyroid hormone only if calcium is elevated
- Stone analysis if/when stone passed

### *Initial Tests (lab, imaging)*

- Noncontrast-enhanced helical CT scan of the abdomen and pelvis has replaced IV pyelogram as the investigation of choice (5)[A].
  - Stone is found most commonly at levels of ureteric luminal narrowing: pelviureteric junction, pelvic brim, and VUJ.
  - Acute obstruction: Proximal ureter and renal pelvis are dilated to the level of obstruction, and perinephric stranding is possible on imaging.
- Renal ultrasound may be as effective with lower radiation at diagnosis as well as identifying obstruction (6)[B].
- X-ray of kidneys, ureter, and bladder to determine if stone is radiopaque or lucent

Calcium oxalate/phosphate stones are radiopaque.

- Uric acid stones are radiolucent.
  - Staghorn calculi (that fill the shape of the renal calyces) are usually struvite and opaque.
  - Cystine stones are faintly opaque (ground-glass appearance).
- Ultrasound has low sensitivity and specificity but is often the first choice for pregnant women.

P.1089

## TREATMENT

### GENERAL MEASURES

- 75% of patients are successfully treated conservatively and pass the stone spontaneously.
- Stones that do not pass usually require surgical intervention.
- 30-50% of patients will have recurrent stones.
- Increase fluid intake; eliminate carbonated drinks.

### MEDICATION

- Medical expulsive therapy:  $\alpha_1$ -antagonists (e.g., tamsulosin) and calcium channel blockers (e.g., nifedipine) improve likelihood of spontaneous stone passage with a number needed to treat (NNT) of  $\approx 5$  (7).
- Category C in pregnancy

### ISSUES FOR REFERRAL

- Urgent referral of patients with UTI/sepsis or acute renal failure/solitary kidney
- Early referral of pregnant patients, large stones (>8 mm), chronic renal failure, children
- Refer patients if no passage at 2 to 4 weeks or poorly controlled pain.

### ADDITIONAL THERAPIES

- Uric acid stone dissolution therapy
  - Alkalinize urine with potassium citrate; keep pH >6.5.
  - Allopurinol 100 to 300 mg/day PO (for those who continue to form stones despite alkalinization of urine)

- Cystine stone dissolution/prevention
  - Alkalinize urine with potassium citrate; keep pH >6.5.
  - Chelating agents: captopril, &agr;-mercapto propionylglycine, D-penicillamine
- Consider altering medications that increase risk of stone formation: probenecid, loop diuretics, salicylic acid, salbutamol, indinavir, triamterene, acetazolamide.
- Vitamin D supplementation has not been proven to induce stone formation.
- Treat hypercalciuria with thiazides on an acute basis only
- Treat hypocitraturia with potassium citrate and high-citrate juices (e.g., orange, lemon).
- Treat enteric hyperoxaluria with oral calcium/magnesium, cholestyramine, and potassium citrate.

## ***SURGERY/OTHER PROCEDURES***

- Immediate relief of obstruction is required for patients with the following conditions:
  - Sepsis
  - Renal failure (obstructed solitary kidney, bilateral obstruction)
  - Uncontrolled pain, despite adequate analgesia
- Emergency surgery for obstruction
  - Placement of a retrograde stent (i.e., endoscopic surgery, usually requires an anesthetic)
  - Radiologic placement of a percutaneous nephrostomy tube
- Elective surgery for stone treatment
  - Extracorporeal shock wave lithotripsy
  - Ureteroscopy with basket extraction/lithotripsy (laser/pneumatic)
  - Percutaneous nephrolithotomy
- Open surgery is uncommon.

## ***INPATIENT CONSIDERATIONS***

### ***Admission-Criteria/Initial Stabilization***

- Analgesia
  - Combination of NSAIDs (ketorolac 30 to 60 mg) and oral opiate

- Parenteral opioid if vomiting or if preceding fails to control pain (morphine 5 to 10 mg IV or IM q4h)
- Antiemetic if required or prophylactically with parenteral narcotics
- Septic patients with urosepsis or pyonephrosis may require IV antibiotics (once blood and urine cultures are taken), IV fluids, and, in severe cases, cardiorespiratory support in intensive care during recovery.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- Patients with ureteric stones who are being treated conservatively should be followed until imaging is clear or stone is visibly passed.
  - Strain urine and send stone for composition.
  - Tamsulosin and nifedipine in selected patients to speed passage
  - Present to the hospital if pain worsens/signs of infection.
  - If pain management is suboptimal or stone does not progress or pass within 2 to 4 weeks, patient should be referred to a urologist and imaging should be repeated.
- Patients with recurrent stone formation should have follow-up with a urologist for metabolic workup: 24-hour urine for volume, pH, creatinine, calcium, cystine, phosphate, oxalate, uric acid, and magnesium.

### *DIET*

#### **ALERT**

- Increased fluid intake for life cannot be overemphasized for decreasing recurrence. Encourage intake of 2 to 3 L/day; advise patient to have clear urine rather than yellow.
- Decrease or eliminate carbonated drinks.
- Patients who form calcium stones should minimize high-oxalate foods such as green leafy vegetables, rhubarb, peanuts, chocolates, and beer.
- Decrease protein and salt intake.
- Lowering calcium intake is inadvisable and even may increase urine calcium excretion.
- Increase phytate-rich foods such as natural dietary bran, legumes and beans, whole cereal (8).

- Avoid excessive vitamin C and/or vitamin D.

## PROGNOSIS

- Spontaneous stone passage depends on stone location (proximal vs. distal) and stone size (<5 mm, 90% pass; >8 mm, 10% pass).
- Stone recurrence: 50% of patients at 10 years

- Decrease protein and salt intake.
- Lowering calcium intake is inadvisable and even may increase urine calcium excretion.

# Urticaria

Irina Pechenko, MD

Katie L. Westerfield, DO

## BASICS

### DESCRIPTION

- A cutaneous lesion involving edema of the epidermis and/or dermis presenting with acute onset and pruritis, returning to normal skin appearance within 24 hours
- Pathophysiology is primarily mast cell degranulation and subsequent histamine release.
- Angioedema may occur with urticaria although angioedema is characterized by sudden pronounced erythematous edema of the lower dermis and subcutis; may take up to 72 hours to remit.
- Pruritus and burning are more commonly associated with urticaria; pain more often with angioedema.
  - Spontaneous urticaria: acute: persists <6 weeks
- Specific extrinsic triggers drugs, foods, infections, envenomation, allergens, and autoimmune
- Underlying etiology may be difficult to pinpoint.
  - Chronic spontaneous urticaria: persists >6 weeks with >2 episodes/week off-treatment
- Recurrent acute urticaria: if symptoms occur <2 times a week.
- For those with chronic urticaria, 40% have concurrent angioedema.
- Chronic infection, pseudoallergy, malignancy including mastocytosis, autoimmunity (especially thyroid), and medications may underlie the remaining 20% (1).
- Inducible urticaria
  - Dermatographism: Skin writing or the appearance of linear wheals at the site of any type of irritation. This is the most common physical urticaria.
  - Cold urticaria: Wheals occur within minutes of rewarming after cold exposure; 95% idiopathic but can be due to infections (mononucleosis, HIV), neoplasia, or autoimmune diseases.

- Delayed pressure urticaria: Urticaria occurs 0.5 to 12 hours after pressure to skin (e.g., from elastic or shoes), may be pruritic and/or painful, and may not subside for several days.
  - Solar urticaria: from sunlight exposure, usually UV; onset in minutes; subsides within 2 hours
  - Heat urticaria: from direct contact with warm objects or air; rare
  - Vibratory urticaria/angioedema: very rare; secondary to vibrations (e.g., motorcycle)
  - Cholinergic urticaria: due to brief increase of core body temperature from exercise, baths, or emotional stress; small pin-sized (5 to 10 mm) wheals surrounded by an erythema but also can have larger wheals. This is the second most common form.
  - Adrenergic urticaria: also caused by stress; extremely rare; vasoconstricted, blanched skin around pink wheals as opposed to cholinergic's erythematous surrounding
  - Contact urticaria: wheals at sites where chemical substances contact the skin, may be either IgE-dependent (e.g., latex) or IgE-independent (e.g., stinging nettle)
  - Aquagenic and solar urticaria: small wheals after contact with water of any temperature or UV light, respectively; rare
- System(s) affected: integumentary
  - Synonym(s): hives; wheals

## ***EPIDEMIOLOGY***

### ***Incidence***

- Equally distributed across all ages: female > male (2:1 in chronic urticaria)
- In 20% of patients, chronic urticaria lasts >10 years (1).

### ***Prevalence***

- 5-25% of the population
- Of people with urticaria, 40% have no angioedema, 40% have urticaria and angioedema, and 20% have angioedema with no urticaria.
- Up to 3% of the population has chronic idiopathic urticaria.

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

- Mast cell degranulation with release of inflammatory reactants, which leads to vascular leakage, inflammatory cell extravasation, and dermal (angioedema) and/or epidermal (wheals/hives) edema

- Histamine, cytokines, leukotrienes, and proteases are main active substances released.
- Spontaneous acute urticaria
  - Bacterial infections: strep throat, sinusitis, otitis, urinary tract
  - Viral infections: rhinovirus, rotavirus, hepatitis B, mononucleosis, herpes
  - Foods: peanuts, tree nuts, seafood, milk, soy, fish, wheat, and eggs; tend to be IgE-mediated; pseudoallergenic foods such as strawberries, tomatoes, preservatives, and coloring agents contain histamine.
  - Drugs: IgE-mediated (e.g., penicillin and other antibiotics), direct mast cell stimulation (e.g., aspirin, NSAIDs, opiates)
  - Inhalant, contact, ingestion, or occupational exposure (e.g., latex, cosmetics)
  - Parasitic infection; insect bite/sting
  - Transfusion reaction
- Spontaneous chronic urticaria
  - Chronic subclinical allergic rhinitis, eczema, and other atopic disorders
  - Chronic indolent infections: *Helicobacter pylori*, fungal, parasitic (*Anisakis simplex*, strongyloidiasis), and chronic viral infections (hepatitis)
  - Collagen vascular disease (cutaneous vasculitis, serum sickness, lupus)
  - Thyroid autoimmunity, especially Hashimoto
  - Hormonal: pregnancy and progesterone
  - Autoimmune antibodies to the IgE receptor *&agr;* chain on mast cells and to the IgE antibody
  - Chronic medications (e.g., NSAIDs, hormones, ACE inhibitors). NSAID sensitivity demonstrated almost in half of adults with chronic urticaria and presents with a worsening of symptoms 4 hours after ingestion (2)[A].
  - Malignancy
  - Physical stimuli (cold, heat, vibration, pressure) in physical urticaria

## Genetics

No consistent pattern known: Chronic urticaria has increased frequency of HLA-DR4 and HLA-D8Q MHC II alleles.

# DIAGNOSIS

## HISTORY

Fast onset; resolves in <24 to 48 hours, pruritis

## PHYSICAL EXAM

- Single/multiple raised, polymorphic indurated plaques with central pallor and edema with an erythematous flare
- Evaluate for underlying conditions including thyroid abnormalities (nodules), bacterial, viral, or fungal infection (e.g., fever).

## DIFFERENTIAL DIAGNOSIS

- Anaphylaxis (may present with urticaria)
- Morbilliform or fixed drug eruptions
- Erythema multiforme
- Systemic lupus erythematosus (SLE), vasculitis, and polyarteritis
- Angioedema without urticaria
- Urticaria pigmentosa/systemic mastocytosis
- Bullous pemphigoid (urticarial stage)
- Arthropod bite
- Atopic/contact dermatitis
- Viral exanthem

## DIAGNOSTIC TESTS & INTERPRETATION

- Directed by clinical suspicion of underlying cause:
  - Allergy skin tests and radioallergosorbent test (RAST) for inhaled allergens, insects, drugs, or foods
  - Infection: Consider pharyngeal culture, LFTs, mononucleosis test, urinalysis in appropriate setting.
- Chronic urticaria (idiopathic or spontaneous CIU/CSU) (3): Extensive lab testing is not indicated and has not proven to improve outcome nor is it cost-effective. Limit lab testing according to clinical history and indication. Skin or IgE testing should be limited to specific

history of provoking allergen (4)[C].

- CBC, ESR, and CRP is recommended by most guidelines.
- Thyroid function tests, LFTs, and urinalysis are recommended by several guidelines.
- Consider allergy skin tests and RAST for inhaled allergens, insects, drugs, or foods; total IgE level.
- Autoimmune: ESR, ANA, RF, complement (e.g., CH50, C3, C4), cryoglobulins in urticarial vasculitis
- Tests for *H. pylori* (e.g., antibodies) in dyspeptic patients. Consider stool for ova and parasites in at-risk individuals.
- Autologous serum skin testing: injection of serum under skin to test for presence of IgE receptor-activating antibodies
- Consider malignancy workup, including serum protein electrophoresis and immunofixation in the proper setting.

---

P.1091

- Use the Urticaria Activity Score (UAS7) for assessing CSU.
- Recently was developed Urticaria Control Test (UCT)
  - The tool to assess disease control in patients with chronic urticaria (spontaneous and inducible) (5)[A].

### *Diagnostic Procedures/Other*

- Food and drug reactions: elimination of (or challenges with) suspected agents
- Physical and special forms of urticaria: challenge tests:
  - Dermatographism: Stroke skin lightly with rounded object and observe for surrounding urticaria.
  - Cold urticaria: ice cube test: Place ice cube on skin for 5 minutes; observe for 10 to 15 minutes.
  - Cholinergic: Exercise to the point of sweating/partial immersion in 42°C bath for 10 minutes.
  - Solar: exposure to different wavelengths of light
  - Delayed pressure: Apply 5-lb sandbag to back for 20 minutes; observe 6 hours later.
  - Aquagenic: Apply water at various temperatures.
  - Vibratory: Apply vibration 4 to 5 minutes with a lab mixing device; observe.

- Skin biopsy with lesions lasting >24 hours

## TREATMENT

### ISSUES FOR REFERRAL

Referral to an allergist, immunologist, or dermatologist for recalcitrant cases

### MEDICATION

#### First Line

- 2nd-generation antihistamine (H<sub>1</sub>) blockers are the first-line treatment of any urticaria in which avoidance of stimulus is impossible or not feasible (6,7)[A]:
  - Fexofenadine (Allegra): 180 mg/day
  - Loratadine (Claritin): 10 mg/day, increasing to 30 mg/day if needed; only medication studied for safe use in pregnancy
  - Desloratadine (Clarinex): 5 mg/day (8)[A]
  - Cetirizine (Zyrtec): 10 mg/day, increasing to 30 mg per day if needed
  - Levocetirizine (Xyzal): 5 mg/day; requires weightbased dosing in children (8)[A]
  - Rupatadine: novel H<sub>1</sub> antagonist with antiplateletactivating factor activity
- 1st-generation antihistamines (H<sub>1</sub>; for patients with sleep disturbed by itching):
  - Older children and adults: hydroxyzine or diphenhydramine 25 to 50 mg q6h
  - Children <6 years of age: diphenhydramine 12.5 mg q6-8h (5 mg/kg/day) or hydroxyzine (10 mg/5 mL) 2 mg/kg/day divided q6-8h
- Precautions and notes: Drowsiness and dry mouth and eyes in 1st-generation H<sub>1</sub> blockers (elderly)

#### Second Line

Doubling the typical 2nd-generation H<sub>1</sub> blocker dosages should be attempted before adding 1stgeneration H<sub>1</sub> or H<sub>2</sub> blockers (6,7,8)[A].

- H<sub>2</sub>-specific antihistamines (beneficial as adjuvants): cimetidine, ranitidine, nizatidine, famotidine

## Third Line

- Corticosteroids: prednisolone 20 to 50 mg/day for max of 10 days; best used only for exacerbations; avoid chronic use (6,7)[C].
- Doxepin: tricyclic antidepressant with strong H<sub>1</sub>- and H<sub>2</sub>-blocking properties; 10 to 30 mg at bedtime; sedation limits usefulness (6)[C].
- Leukotriene antagonists (montelukast, zileuton, and zafirlukast): safe and worth trying in chronic, unresponsive cases; useful alone but best used in addition to antihistamines; limited data on use in treating acute urticaria (2)[A]
- Refractory symptoms
  - Omalizumab: anti-IgE; effective, expensive. 150 to 300 mg SQ q2-4wk. Restricted to allergists and those who can manage acute anaphylaxis (3,6,9,11)[A], significantly reduce the urticarial symptoms of CIU/CSU at 12 weeks. The best effects is reached with omalizumab dose 300 mg (3)[A]. Omalizumab is currently the only licensed treatment for H<sub>1</sub>-antihistamine-refractory chronic spontaneous urticaria, has a favorable risk/benefit ratio, and was well tolerated in clinical studies (2).
  - Cyclosporine: well-studied, effective (2.5 to 5 mg/kg/day); best used in combination with antihistamines; significant renal side effects (6,7)[C]
  - Methotrexate: antifolate; proven useful in recalcitrant cases; GI upset most common complaint; long-term requires LFT monitoring
  - UV therapy decreases number of mast cells; has shown promise in the treatment of mastocytosis-induced urticaria (7)[C].
- Adding Vitamin D 4,000 U/day for 12 weeks may decrease the symptoms and USS score (10) [C].

## INPATIENT CONSIDERATIONS

### Admission Criteria/Initial Stabilization

Educating patient on use of EpiPen as pathophysiology similar. If the airway is threatened, immediate consult to evaluate for laryngeal edema and need for airway access.

## ONGOING CARE

### PROGNOSIS

Resolution of acute symptoms: 70% <72 hours. chronic urticaria: 35% symptom-free in a year;

another 30% will see symptom reduction

## Codes

&NA;

### ICD10

- L50.9 Urticaria, unspecified
- L50.1 Idiopathic urticaria
- L50.8 Other urticaria

## Clinical Pearls

&NA;

- Chronic urticaria with <2 episodes/week should be approached as acute.
- Antihistamines are the best studied and most efficacious therapy but may require higher-than-normal doses for efficacy.
- Lesions lasting >24 hours should be evaluated for urticarial vasculitis.

# Uterine and Pelvic Organ Prolapse

Maryse A. Pedoussaut, MD

John Delzell Jr., MD, MSPH

Suzanne Minor, MD, FAAFP

## BASICS

### DESCRIPTION

- Symptomatic descent of one or more of (1,2)
  - The anterior vaginal wall (bladder or cystocele)
  - The posterior vaginal wall (rectum or rectocele)
  - The apex of the vagina (uterine cervix descent and prolapse)
  - The vault (cuff) after hysterectomy (vault prolapse)
- Prolapses above or to the hymen are not symptomatic (2).
- Associated symptoms (2)
  - Feeling of vaginal or pelvic pressure
  - Heaviness
  - Bulging
  - Bowel or bladder symptoms
- Cost associated with treatment is more than \$1 billion annually ( $\div$ 200,000 surgeries/year) (2).

### EPIDEMIOLOGY

#### *Incidence*

Pelvic organ prolapse (POP) is common but not always symptomatic. It does not always progress with time. In a 3-year prospective cohort study of 249 women, prolapse increased by at least 2 cm in 11% and regressed by 2 cm in 3% (2).

#### *Prevalence*

- A national survey of 7,924 women (over 20 years of age) found a prevalence of 25% for one

or more pelvic floor disorders (including urinary incontinence, fecal incontinence, and POP). Prevalence of POP was 2.9% (3).

- The prevalence of lower urinary tract symptoms is as high as 50% in parous women. 11% of all women have surgery for POP or lower urinary tract symptoms by 80 years old (4).
- 3-6% of women who present for gynecologic care have a prolapse beyond hymen (2).

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Insidious process begins long before symptoms develop.
- There is a complex interaction between the pelvic floor musculature, connective tissue, and the vaginal wall, which provides support from the perineum to the sacrum (2). Integrity of levator ani is essential to this support system by providing a platform on which the pelvic organs rest (2).
- Symptomatic women typically have multiple defects, including laxity of supporting tissue and damage to the levator ani (2).
- Half of anterior prolapse can be attributed to apical descent of the vagina (2).

## *RISK FACTORS*

- Vaginal childbirth (2): Women who have delivered two children vaginally have a relative risk of 8.4 and every additional child (up to five deliveries) increases the risk of prolapse by 10-20% (2).
- Age: Every 10 years of age increases the risk of prolapse by 40% (2). POP will become more prevalent, as the elderly population is expected to double by 2030 (5).
- Obesity: BMI >25 may increase the risk of developing prolapse (2).
- Constipation: independent risk factor in a survey of more than 2,000 women (2)
- Race: White and Hispanic women may be at higher risk than black or Asian women (2).
- Occupation (heavy lifting): variable support in the literature (2)
- Hysterectomy: variable support in the literature (2)
- Obstetric factors (operative delivery, infant weight, length of pushing in second stage of labor): variable support in the literature (2)

## *GENERAL PREVENTION*

There is some evidence that pelvic floor muscle training (Kegel exercises) may decrease the risk of symptomatic POP (6)[B]. Weight loss and proper management of conditions that cause increase in intraabdominal pressure may help prevent the problem.

## COMMONLY ASSOCIATED CONDITIONS

- Urinary incontinence
- Other urinary symptoms (4)
  - Urgency
  - Frequency

## DIAGNOSIS

### HISTORY

- Less than half of women discuss symptoms with PCP. Only 10-12% seek medical attention. Barriers include embarrassment, social stigma, ability to cope, belief that POP is part of the aging process, belief that treatment options are limited, and fear of surgery (4).
- Common symptoms include the following:
  - Feeling a bulge in vagina
  - Something “falling out” of vagina
  - Pelvic pressure
  - Difficulty with voiding or defecation
  - Urgency
  - Frequency
  - Incontinence (urinary or fecal)
  - Constipation
- Document the presence, duration, and severity of urinary, bowel, or prolapse symptom. Assess impact on sexual function and quality of life with validated questionnaires (PISQ 9 OR 12) (1,7).
- Assess past medical history.
  - Gravity and parity/obstetric history
  - History of ascites
  - Chronic constipation
  - Document physical impairment (mobility, dexterity, or visual acuity), as this may affect management (1).
  - Document the patient's desire, goals, and expectation (1).

## PHYSICAL EXAM

- Abdominal examination to document any distention or masses
- Complete pelvic and rectal examination. Have patient cough or strain, particularly in an upright (standing) position while examining the distal vagina.
- The GOLD STANDARD is to measure vaginal descent using the Pelvic Organ Prolapse Quantification (POPQ) scale, which is a scale that describes the prolapse in relationship to the vaginal hymen (2). The validated simplified version has four measurements with classification in four stages. Patient is supine with the head of the bed at 45 degrees, performing Valsalva.
  - Stage 1: prolapse in which the distal point is superior or equal to 1 cm above hymen
  - Stage 2: prolapse in which the distal point is between 1 cm above and 1 cm below hymen
  - Stage 3: prolapse in which the distal point is superior or equal to 1 cm below the hymen, but some vaginal mucosa is not everted
  - Stage 4: complete vaginal vault eversion (ÖprocidentiaÓ). Entire vaginal mucosa everted (2)
- A split speculum can be used to observe anterior, posterior, and apical parts of the vagina successively.
- Patient should be standing for maximum descent (2).

## DIFFERENTIAL DIAGNOSIS

- Rectal prolapse
- Hemorrhoids
- Bartholin cyst
- Cervical elongation

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- Urinalysis if symptomatic POP (1)
- Renal function (serum creatinine) if urinary incontinence and probability of renal impairment (1)
- Imaging: not routinely recommended (1)

### *Follow-Up Tests & Special Considerations*

- Postvoid residual if patient has urinary incontinence
- Urodynamic testing prior to invasive treatment or after treatment failure to plan further therapy (1)
- Imaging of upper urinary tract if hematuria or back pain (1)
- Cystoscopy recommended if patient has hematuria, pain, or discomfort suggesting bladder lesion (1)
- Colonoscopy or sigmoidoscopy if patient has fecal incontinence (1)
- Colonoscopy, air contrast barium enema, and/or computed tomography if change in bowel habits or rectal bleeding (1)

## TREATMENT

### GENERAL MEASURES

- Treatment should take into account type and severity of symptoms, patient's age, other comorbid conditions, sexual function, infertility, and risk of recurrence.
- Treatment for asymptomatic patients
  - Stage 1 or 2: clinical observation (2)
  - Stage 3 or 4: regular follow-up and evaluation (every 6 to 12 months) (2)
- Treatment is indicated when there is urinary/bowel obstruction or hydronephrosis regardless of the degree of prolapse (2).

P.1093

- A vaginal pessary should be considered in all women presenting with symptomatic prolapse (8) [B].
  - There are more than 13 types of silicone devices that may be inserted into the vagina to support the pelvic organs.
  - The most commonly used pessaries are the ring pessary and Gellhorn (8).
  - They may prevent prolapse progression and may prove to be an appropriate prevention strategy in the future because the surgical failure rate is around 30% (2).
  - Most women can be successfully fitted with a pessary (8)[B].
  - Satisfaction rate for patients using pessaries is very high (8)[B].
- Complications may be seen with neglected pessaries, such as erosions, abrasions, ulcerations,

and vaginal bleeding. Minor complications such as vaginal discharge and odor can be treated without discontinuing pessary use (8)[B]. Vaginal erosion can be treated by removal of pessary and optional vaginal estrogen supplementation.

## *MEDICATION*

### *First Line*

- Treatment of vaginal atrophy with topical estrogens may be beneficial for symptomatic POP (9) [B] if there are no contraindications. Suggested to use in conjunction with pelvic floor muscle training (9)
- Vaginal creams
  - Estradiol cream 0.01% (Estrace)
  - Conjugated estrogens 0.625 mg/day (Premarin)
- Vaginal tablet
  - Estradiol 10 &mgr;g (Vagifem)
- Vaginal ring
  - Estradiol 2 mg (Estring)

## *ISSUES FOR REFERRAL*

Referral when pessary or surgery is necessary

## *ADDITIONAL THERAPIES*

Pelvic floor muscle training may reduce the symptoms of POP (1). Pelvic floor muscle training does not affect the degree of prolapse, only the symptoms (1).

## *SURGERY/OTHER PROCEDURES*

- Reconstructive procedures are done with the goal of restoration of vaginal anatomy.
- Reconstructive surgery is associated with a high rate of failure (1 in 3 lifetime risk of repeat surgery). New procedures, using surgical mesh and graft material, have higher success rates but limited follow-up or comparative data (2).
- Abdominal procedures such as sacral colpopexy using graft material have a higher success rate but a longer operating time, longer time to return to normal activity levels, and an increased cost (10)[B]. There may be resulting problems with sexual function and bladder/bowel complaints (2).

## ONGOING CARE

### PATIENT EDUCATION

- Patients should be educated about pessary complications and possible symptoms of POP if they are still asymptomatic.
- Limit caffeine product and bladder irritants if urinary symptoms.
- Using insoluble fibers may help patients with bowel complaints such as constipation.

### COMPLICATIONS

- There is a risk of vaginal mesh extrusion, erosions, dyspareunia, and pelvic pain after surgical repair (11).
- Delays in diagnosis (4)[B]
  - 61% reported POP symptoms to a physician.
  - 65.9% blamed themselves for the delay (fear of surgery, embarrassment).
  - 1/3 of women blame their physician for the delay in diagnosis.

 **Codes**

**&NA;**

## ICD10

- N81.9 Female genital prolapse, unspecified
- N81.10 Cystocele, unspecified
- N99.3 Prolapse of vaginal vault after hysterectomy

## Clinical Pearls

**&NA;**

- Many women do not discuss POP with their doctorÑask routinely.
- Vaginal pessary should be considered in all patients with symptomatic prolapse.
- Traditional surgical treatment has a high long-term failure rate (1 in 3).

# Uterine Myomas

Jessica M. Schechtman, DO

Michael P. Hopkins, MD, MEd

## BASICS

### DESCRIPTION

- Uterine leiomyomas are well-circumscribed, pseudoencapsulated, benign monoclonal tumors composed mainly of smooth muscle with varying amounts of fibrous connective tissue (1,2).
- Three major subtypes
  - Subserous: common; external; may become pedunculated
  - Intramural: common; within myometrium; may cause marked uterine enlargement
  - Submucous:  $\pm$ 5% of all cases; internal, evoking abnormal uterine bleeding and infection; occasionally protruding from cervix
- Rare locations: broad, round, and uterosacral ligaments
- System affected: reproductive
- Synonym(s): fibroids; myoma; fibromyoma; myofibroma; fibroleiomyoma

### EPIDEMIOLOGY

#### Incidence

- Cumulative incidence up to 80%
  - 60% in African American women by age 35 years; 80% by age 50 years
  - 40% in Caucasian women by age 35 years; 70% by age 50 years (1,3,4)
- Incidence increases with each decade during reproductive years.
- Rarely seen in premenarchal females
- Predominant sex: females only

### ETIOLOGY AND PATHOPHYSIOLOGY

- Enlargement of benign smooth muscle tumors that may lead to symptoms affecting the reproductive, GI, or genitourinary system
- Complex multifactorial process involving transition from normal myocyte to abnormal cells and then to visibly evident tumor (monoclonal expansion)
  - Hormones (1): Increases in estrogen and progesterone are correlated with myoma formation (i.e., rarely seen before menarche). Estrogen receptors in myomas bind more estradiol than normal myometrium (2).
  - Growth factors (1)
    - Increased smooth muscle proliferation (transforming growth factor *&bgr;*; [TGF-*&bgr;*], basic fibroblast growth factor [bFGF])
    - Increase DNA synthesis (epidermal growth factor [EGF], platelet-derived growth factor [PDGF], activin, myostatin)
    - Stimulate synthesis of extracellular matrix (TGF-*&bgr;*)
    - Promote mitogenesis (TGF-*&bgr;*, EGF, insulin-like growth factor [IGF], prolactin)
    - Promote angiogenesis (bFGF, vascular endothelial growth factor [VEGF])
  - Vasoconstrictive hypoxia (1): proposed, but not confirmed, mechanism of myometrial injury during menstruation

## Genetics

- A variety of somatic chromosomal rearrangements have been described in 40% of uterine myomas.
  - Mutations in the gene encoding mediator complex subunit 12 (MED12) on the X chromosome were found in 70% of myomas in one study (3).
- Higher levels of aromatase and therefore estrogen have been found in myomas in African American women (3).

## RISK FACTORS

- African American heritage
  - 2.9 times greater risk than Caucasian women; occur at a younger age, are more numerous, larger, and more symptomatic (1,4)
- Early menarche (<10 years)
- Oral contraceptive use before 16 years old (4)

- Nulliparous
- Hypertension
- Familial predisposition
  - 2.5 times more likely in women with a first-degree relative with myomas (1)
- Obesity
  - Risk increases by 21% with each 10 kg of weight gain (1).
- Alcohol
- Risk decreased by: parity, progesterone only contraceptives, diet (fruits, veggies, low fat dairy) (4)

## COMMONLY ASSOCIATED CONDITIONS

Endometrial and breast cancer also associated with high, unopposed estrogen stimulation

## DIAGNOSIS

### HISTORY

- Usually asymptomatic; 30% present with abnormal symptoms—usually enlarged uterus or heavy bleeding (2,4).
- Symptoms include the following:
  - Abnormal uterine bleeding: usually heavy/prolonged menses
  - Pain: infrequent; usually associated with torsion of pedunculated myoma, degeneration, or cervical dilation by submucous myoma near cervical os
  - Pressure on bladder: suprapubic discomfort, urinary frequency/obstruction
  - Pressure on rectosigmoid: may cause low back pain, constipation
  - Infertility: rare, estimated 1-2.5% (2); usually from submucous myoma distorting the uterine cavity or interference with implantation

### ALERT

Rapid growth, particularly in perimenopausal/postmenopausal patients; may indicate sarcoma. Extremely rare, 0.1-0.3% of cases (2)

## PHYSICAL EXAM

- Usually incidental finding on abdominal and pelvic exam

- Firm, smooth nodules/masses arising from uterus
- Masses are mobile without tenderness.

## ***DIFFERENTIAL DIAGNOSIS***

- Intrauterine pregnancy
- Cancer, including ovarian, uterine, or leiomyosarcoma
- Cecal/sigmoid tumor
- Appendiceal abscess
- Diverticulitis
- Pelvic kidney
- Urachal cyst

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Pregnancy test
- Hemoglobin
- Pelvic ultrasound: standard confirmatory test; shows characteristic hypoechoic appearance (4,5)
- Saline infusion hysterosonography: helps to distinguish submucosal myomas
- Hysterosalpingogram: evaluates the contour of the endometrial cavity (5)
- CT scan or MRI: provides info on degeneration and special relationships (4); may help to differentiate complex cases or used when uterine artery embolization is planned (5)[B]

### **Follow-Up Tests & Special Considerations**

Consider cancer antigen 125 (CA-125): may be slightly elevated in some cases of uterine myoma but generally more useful in differentiating myomas from various gynecologic adenocarcinomas

- IV pyelogram: if suspect ureteral distortion (5)
- Barium enema

### ***Diagnostic Procedures/Other***

- Fractional dilation and curettage: aids in ruling out cervical/uterine carcinomas when clinically

suspicious

- Hysteroscopy: helps to diagnose submucosal/intracavitary myomas
- Laparoscopy: useful in complex cases and to rule out other pelvic diseases/disorders

## *Test Interpretation*

- Myomas are usually multiple and vary in size and location; have been reported up to 100 lb
- Gross pathology: firm tumors with characteristic whorl-like trabeculated appearance; a thin pseudocapsular layer is present.
- Microscopic: bundles of smooth muscle mixed with varying amounts of connective tissue elements running in different directions
- Cellular variant has a preponderance of muscle cells. Mitoses are rare.
- May undergo various types of degeneration
  - Hyaline degeneration: very common
  - Calcification: late result of circulatory impairment to myomas
  - Infection and suppuration: most common with submucosal myomas
  - Necrosis: most common with pedunculated myomas secondary to torsion

## **TREATMENT**

- Treatment must be individualized and based on symptoms, fertility desires, and time until menopause.
- Medical therapy may be of benefit.
- Patients with minimal symptoms may be treated with iron preparations and analgesics.
- Conservative management of asymptomatic myomas
  - Pelvic exams and ultrasounds at 3-6-month intervals if size remains stable
  - Substantial regression usually occurs after menopause.
- Surgical options should be considered if symptomatic or worrisome myomas are unresponsive to conservative/medical management.

## **GENERAL MEASURES**

Patients not desiring pharmacologic therapy or surgery may consider the following:

- Uterine artery embolization: averages 50% shrinkage of myomas (6)[A]; painful and may cause

ovarian failure (1-2%), amenorrhea, postembolization syndrome, or other complications; shorter hospital stay and quicker recovery but no difference in satisfaction compared with hysterectomy (2,4)[B]; high reintervention rate (15-32% by 2 years) compared to hysterectomy/myomectomy (7% by 2 years) (6)

- MR-guided focused ultrasound (MRgFUS): noninvasive, ultrasound transducer passes through abdominal wall and causes coagulative necrosis of fibroid; up to 98% reduction in myoma volume and symptoms. Not appropriate for some types of myomas (2)[B]. Efficacy may be comparable with other hysterectomy-sparing procedures (7)[B]. Fertility has been shown to be preserved (4)[A] although risks and outcomes data is limited (4).

## *MEDICATION*

- Progestins may reduce overall uterine size (5)[B].
  - Norethindrone 10 mg/day
  - Medroxyprogesterone 200 mg IM monthly
  - Levonorgestrel intrauterine device (2)[B]
- Combination oral contraceptives: may help prevent development of new fibroids and control bleeding
  - Contraindications: history of thromboembolic events
- Gonadotropin-releasing hormone agonists
  - Nafarelin (nasal spray), goserelin acetate, and leuprolide
  - Induces abrupt artificial menopause; may reduce myoma symptoms dramatically; induces atrophy of myomas by up to 40% in 2 to 3 months (5)[B]
  - May be valuable as preoperative adjunct to myomectomy/hysterectomy by allowing recovery of anemia, donation of autologous blood, and possibly converting abdominal to vaginal hysterectomy (4,5,8)[B]
  - Not recommended for use >6 months because of osteoporosis risk
  - Following discontinuation, myomas return within 60 days to pretherapy size.
- Antiprogesterones
  - Mifepristone

- Shown to have similar reduction in myoma size as gonadotropin-releasing hormone agonists (7)[B]
- Decreases heavy bleeding and increases quality of life (9)[A]
- Selective progesterone receptor modulator (SPRM)
  - Ulipristal acetate: may be as effective as gonadotropin-releasing hormones with fewer side effects (4)[B]

## *ISSUES FOR REFERRAL*

- Medical therapy may be initiated by a primary care physician/gynecologist after adequate pelvic examination.
- Surgical considerations may be pursued with gynecologic consultation.
- Uterine embolization may be discussed with an interventional radiologist.

## *SURGERY/OTHER PROCEDURES*

- Surgical management is indicated in the following situations (5)[B]:
  - Excessive uterine size or excessive rate of growth (except during pregnancy)
  - Submucosal myomas when associated with hypermenorrhea
  - Pedunculated myomas that are painful or undergo torsion, necrosis, and hemorrhage.
  - If a myoma causes symptoms from pressure on bladder/rectum
  - If differentiation from ovarian mass is not possible
  - If associated pelvic disease is present (endometriosis, pelvic inflammatory disease)
  - If infertility/habitual abortion is likely due to the anatomic location of the myoma
- Surgical procedures
  - Preliminary pelvic examination, Pap smear, and endometrial biopsy should be performed to rule out malignant/premalignant conditions.
  - Hysterectomy: may be performed vaginally, laparoscopically, robotically, or by laparotomy
    - Effective in relieving symptoms and improving quality of life (4,7)[B]
    - Similar fertility and live birth rates between laparoscopic and abdominal myomectomy (2) [B]
    - FDA discourages the use of laparoscopic power morcellation during hysterectomy or myomectomy for uterine fibroids given the risk of spreading an occult malignancy and all

patient should be counseled preoperatively of risk (4).

- Abdominal, laparoscopic, robotic, or hysteroscopic myomectomy may be performed in younger women who want to maintain fertility (5,10)[B].
- Hysteroscopic/laparoscopic cautery/laser myoma resection can be performed in selected patients.
- Endometrial ablation: for small submucosal myomas

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Usually outpatient
- Inpatient for some surgical procedures

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- Pelvic examination and ultrasound: every 2 to 3 months for newly diagnosed symptomatic/excessively large myomas
- Hemoglobin and hematocrit: if uterine bleeding is excessive
- Once uterine size and symptoms stabilize, monitor every 6 to 12 months although no high quality evidence exists (4).

#### ***DIET***

No restrictions

### ***PATIENT EDUCATION***

- Society of Interventional Radiology: <http://sirweb.org/patients/uterine-fibroids/>
- U.S. Department of Health and Human Services:  
<http://www.womenshealth.gov/publications/our-publications/fact-sheet/uterine-fibroids.html?from=AtoZ>
- American Congress of Obstetricians and Gynecologists: <http://www.acog.org>

## PROGNOSIS

- Resection of submucosal fibroids has been associated with increased fertility (7)[B].
- At least 10% of myomas recur after myomectomy; however, only 25% require further treatment (4,7)[B].

## COMPLICATIONS

- May mask other gynecologic malignancies (e.g., uterine sarcoma, ovarian cancer)
- Degenerating fibroids may cause pain and bleeding.
- May rarely prolapse through the cervix

## ***Pregnancy Considerations***

- Rapid growth of fibroids is common.
- Pregnant women may need additional fetal testing if placenta is located over or near fibroid.
- Complications during pregnancy: abortion, premature labor, 2nd-trimester rapid growth leading to degeneration/pain, 3rd-trimester fetal malpresentation, and dystocia during labor and delivery
- Cesarean section is recommended if the endometrial cavity was entered during myomectomy due to increased risk of uterine rupture.

## ***Geriatric Considerations***

In postmenopausal patients with newly diagnosed uterine myoma/enlarging uterine myomas have a high suspicion of uterine sarcoma/other gynecologic malignancy.

Laughlin SK, Schroeder JC, Baird DD. New directions in the epidemiology of uterine fibroids. *Semin Reprod Med.* 2010;28(3):204-217.

## Codes

&NA;

### ICD10

- D25.9 Leiomyoma of uterus, unspecified
- D25.2 Subserosal leiomyoma of uterus
- D25.1 Intramural leiomyoma of uterus

## Clinical Pearls

&NA;

- Uterine myomas are benign smooth muscle tumors composed mainly of fibrous connective tissue.
- Usually incidental finding on pelvic exam or ultrasound but may cause pelvic pain and pressure, abnormal uterine bleeding, and/or infertility
- Management ranges from conservative to medical to surgical.

# Uveitis

Shailendra K. Saxena, MD, PhD

Mikayla Spangler, PharmD

Laura K. Klug, PharmD

## BASICS

### DESCRIPTION

- A nonspecific term used to describe any intraocular inflammatory disorder
- Symptoms vary depending on depth of involvement and associated conditions.
- The uvea is the middle layer of the eye between the sclera and retina. The anterior part of the uvea includes the iris and ciliary body. The posterior part of the uvea is the choroid.
  - Anterior uveitis: refers to ocular inflammation limited to the iris (iritis) alone or iris and ciliary body (iridocyclitis)
  - Intermediate uveitis: refers to inflammation of the structures just posterior to the lens (pars planitis or peripheral uveitis)
  - Posterior uveitis: refers to inflammation of the choroid (choroiditis), retina (retinitis), or vitreous near the optic nerve and macula
- System(s) affected: nervous
- Synonym(s): iritis; iridocyclitis; choroiditis; retinochoroiditis; chorioretinitis; anterior uveitis; posterior uveitis; pars planitis; panuveitis. Synonyms are anatomic descriptions of the focus of the uveal inflammation.

### Geriatric Considerations

The inflammatory response to systemic disease may be suppressed.

### Pediatric Considerations

- Infection should be the primary consideration.
- Allergies and psychological factors (depression, stress) may serve as a trigger.
- Trauma is also a common cause in this population.

## *Pregnancy Considerations*

May be of importance in the selection of medications

## *EPIDEMIOLOGY*

- Predominant age: all ages
- Predominant sex: male = female, except for human leukocyte antigen B27 (HLA-B27) anterior uveitis: male > female, autoimmune etiology: female > male

## *Incidence*

- Overall prevalence is 38 to 714 cases/100,000 annual incidence.
- Anterior uveitis is the most common.

## *Prevalence*

Iritis is 4 times more prevalent than posterior uveitis.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Infectious: may result from viral, bacterial, parasitic, or fungal etiologies
- Suspected immune-mediated: possible autoimmune or immune-complex-mediated mechanism postulated in association with systemic (especially rheumatologic) disorders
  - Autoimmune uveitis (AIU) patients should be referred to an ophthalmologist for local treatment.
- Isolated eye disease
- Idiopathic (÷25%)
- Some medications may cause uveitis. The most causative medications include rifabutin, bisphosphonates, sulfonamides, metipranolol, topical corticosteroids, brimonidine, prostaglandin analogs, anti-vascular endothelial growth factor (VEGF) agents, bacillus Calmette-Guerin (BCG) vaccination, and systemic and intraocular cidofovir.
- Masquerade syndromes: diseases such as malignancies that may be mistaken for primary inflammation of the eye

## *Genetics*

- No specific pattern for uveitis in general
- Iritis: 50-70% are HLA-B27-positive.

- Predisposing gene for posterior uveitis associated with Behçet disease may include HLA-B51.

## **RISK FACTORS**

- No specific risk factors
- Higher incidence is seen with specific associated conditions.

## **COMMONLY ASSOCIATED CONDITIONS**

- Viral infections: herpes simplex, herpes zoster, HIV, cytomegalovirus
- Bacterial infections: brucellosis, leprosy, leptospirosis, Lyme disease, propionibacterium infection, syphilis, tuberculosis (TB), Whipple disease
- Parasitic infections: acanthamebiasis, cysticercosis, onchocerciasis, toxocariasis, toxoplasmosis
- Fungal infections: aspergillosis, blastomycosis, candidiasis, coccidioidomycosis, cryptococcosis, histoplasmosis, sporotrichosis
- Suspected immune-mediated: ankylosing spondylitis, Behçet disease, Crohn disease, drug or hypersensitivity reaction, interstitial nephritis, juvenile rheumatoid arthritis, Kawasaki disease, multiple sclerosis, psoriatic arthritis, Reiter syndrome, relapsing polychondritis, sarcoidosis, Sjögren syndrome, systemic lupus erythematosus, ulcerative colitis, vasculitis, vitiligo, Vogt-Koyanagi (Harada) syndrome
- Isolated eye disease: acute multifocal placoid pigmentary epitheliopathy, acute retinal necrosis, bird-shot choroidopathy, Fuchs heterochromatic cyclitis, glaucomatocyclitic crisis, lens-induced uveitis, multifocal choroiditis, pars planitis, serpiginous choroiditis, sympathetic ophthalmia, trauma
- Masquerade syndromes: leukemia, lymphoma, retinitis pigmentosa, retinoblastoma

## **DIAGNOSIS**

### **HISTORY**

- Decreased visual acuity
- Pain, photophobia, blurring of vision (1)[C]
  - Usually acute
- Anterior uveitis (~80% of patients with uveitis) (1)[C]
  - Generally acute in onset
  - Deep eye pain
  - Photophobia (consensual)

- Intermediate and posterior uveitis (2)
  - Unresolving floaters
  - Generally insidious in onset
  - More commonly bilateral

## *PHYSICAL EXAM*

Slit-lamp exam and indirect ophthalmoscopy are necessary for precise diagnosis (1)[C].

- Anterior uveitis (÷80% of patients with uveitis)
  - Conjunctival vessel dilation
  - Perilimbal (circumcorneal) dilation of episcleral and scleral vessels (ciliary flush)
  - Small pupillary size of affected eye
  - Hypopyon or hyphema (WBCs or RBCs pooled in the anterior chamber)
  - Frequently unilateral (95% of HLA-B27-associated cases); if first occurrence and otherwise asymptomatic, no further diagnostic testing is needed (1)[C].
  - Bilateral involvement and systemic symptoms (fever, fatigue, abdominal pain) may be associated with interstitial nephritis (1)[C].
  - Systemic disease is most likely to be associated with anterior uveitis (in one study, 53% of patients were found to have systemic disease) (1)[C].
- Intermediate and posterior uveitis
  - More commonly bilateral
  - Posterior inflammation will generally cause minimal pain or redness unless associated with an iritis.

## *DIFFERENTIAL DIAGNOSIS*

- Acute angle-closure glaucoma
- Conjunctivitis
- Episcleritis
- Keratitis
- Scleritis

## DIAGNOSTIC TESTS & INTERPRETATION

No specific test for the diagnosis of uveitis. Tests for etiologic factors or associated conditions should be based on history and physical exam (1)[C].

### Initial Tests (lab, imaging)

- CBC, BUN, creatinine (interstitial nephritis) (1)[C]
- HLA-B27 typing (ankylosing spondylitis, Reiter syndrome) (1)[C]
- Antinuclear antibody, ESR (systemic lupus erythematosus, Sjögren syndrome) (1)[C]
- Venereal disease research laboratory (VDRL) test, fluorescent titer antibody (syphilis) (1)[C]
- Fluorescent treponemal antibody absorption (FTA-ABS) or microhemagglutination assay for antibodies to *Treponema pallidum* (MHA-TP) (1)[C]
- Purified protein derivative (PPD) tuberculin skin test (TB) (1)[C]
- Lyme serology (Lyme disease) (1)[C]
- Disorders that may alter lab results: immunodeficiency
- Chest x-ray (sarcoidosis, histoplasmosis, TB, lymphoma) (1)[C]
- Sacroiliac radiograph (ankylosing spondylitis) (1)[C]

### Diagnostic Procedures/Other

Slit-lamp exam (1)[C]

### Test Interpretation

- Keratic precipitates
- Inflammatory cells in anterior chamber or vitreous
- Synechiae (fibrous tissue scarring between iris and lens)
- Macular edema
- Perivasculitis of retinal vessels

## TREATMENT

### GENERAL MEASURES

- Outpatient care with urgent ophthalmologic consultation

- Medical therapy is best initiated following full ophthalmologic evaluation.

- Treatment of underlying cause, if identified
- Anti-inflammatory therapy

## MEDICATION

### *First Line*

- The treatment depends on the etiology, location, and severity of the inflammation.
- Prednisolone acetate 1% ophthalmic suspension: 2 drops to the affected eye q1h initially, tapering to once a day with improvement
  - Contraindications
    - Hypersensitivity to the medication or component of the preparation
    - Topical corticosteroid therapy is contraindicated in uveitis secondary to infectious etiologies, unless used in conjunction with appropriate anti-infectious agents.
  - Precautions
    - Topical corticosteroids may increase intraocular pressure, increase susceptibility to infections, impair corneal or scleral wound healing, or cause corneal epithelial toxicity or crystalline keratopathy. Prolonged use may cause cataract formation and exacerbate existing herpetic keratitis, which may masquerade as iritis.
  - Significant possible interactions
- Systemic corticosteroids are useful for maintenance therapy for patients with noninfectious uveitis. These should always be used with other immunosuppressive medications for steroid-sparing effects; prednisone 5 to 10 mg daily (3,4)[B].
- Cycloplegic agents may be used to dilate the eye and relieve pain. Agents include scopolamine hydrobromide 0.25% (Isopto Hyoscine) or atropine 1% 1 to 2 drops up to QID or homatropine hydrobromide (Isopto) 2% or 5% 1 to 2 drops BID or as often as q3h if necessary (1)[C].
  - Contraindications
    - Cycloplegia is contraindicated in patients known to have, or be predisposed to, glaucoma.
  - Precautions
    - Use extreme caution in infants, young children, and elderly because of increased susceptibility to systemic effects.

## Second Line

- Anti-inflammatory: prednisolone sodium phosphate 1%, dexamethasone sodium phosphate 0.1%, dexamethasone suspension, rimexolone 1% (Vexol), and loteprednol etabonate 0.5% (Lotemax), difluprednate (Durezol) 0.05% (1,4)[C]
  - Rimexolone 1% (Vexol) may be equally effective as prednisolone acetate 1% for short-term treatment of anterior uveitis (1)[C].
  - Loteprednol etabonate (Lotemax) may not be as effective as prednisolone acetate 1% but may be less likely to increase intraocular pressure in cases of acute anterior uveitis.
- Periocular corticosteroids may be injected with triamcinolone acetonide being most commonly used; 40 mg/1 mL (5)[C].
- Intravitreal corticosteroid deposits may also be used for long-term maintenance. Fluocinolone acetonide (Retisert) 590  $\mu$ g released >30 months, dexamethasone (Ozurdex) 0.7 mg released slowly >3 to 6 months (4,5)[B].
  - Retisert has caused all patients to develop cataracts and significant increases in intraocular pressure in about 2/3 of patients, whereas Ozurdex had only 1/4 of patients require medication for increased intraocular pressure and 15% develop cataracts (5)[C].
- Intravitreal corticosteroid injections are used only in severe cases of recurrence; triamcinolone acetonide 4 to 20 mg/0.1 mL, dexamethasone phosphate 0.4 mg/0.1 mL, dexamethasone implant (Ozurdex)
  - Ozurdex has a longer effect than triamcinolone acetonide.
- Immunosuppressive agents including antimetabolites (methotrexate, azathioprine, and mycophenolate mofetil), T-cell inhibitors (cyclosporine, tacrolimus, and sirolimus), and alkylating agents (cyclophosphamide, chlorambucil) may be employed in cases resistant to initial treatment but close monitoring is required (4,5)[C].
- Although biologic therapy has been used for refractory uveitis, the sparsity of randomized clinical trials as well as high cost and adverse effect potential of these agents limit their use (3,4)[C].
- Systemic and ophthalmic preparations of NSAIDs may provide some symptom relief (1)[C].

## ISSUES FOR REFERRAL

Caution should be used when using empiric treatment; referral to an ophthalmologist is recommended in most cases.

## ***SURGERY/OTHER PROCEDURES***

Various surgical procedures may be used therapeutically for visual rehabilitation, diagnostically, or to manage complications associated with uveitis (6).

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- Complete history and physical to evaluate for associated systemic disease
- Ophthalmologic follow-up as recommended by consultant

### ***PATIENT EDUCATION***

- Instruct on proper method for instilling eye drops.
- Wear dark glasses if photophobia is a problem.

### ***PROGNOSIS***

- Depends on the presence of causal diseases or associated conditions
- Uveitis resulting from infections (systemic or local) tends to resolve with eradication of the underlying infection.
- Uveitis associated with seronegative arthropathies tends to be acute (lasting <3 months) and frequently recurrent.

### **COMPLICATIONS**

- Cycloplegia: paralysis of the ciliary muscle of the eye, resulting in a loss of accommodation
- Loss of vision as a result of the following:
  - Keratic precipitate deposition on the corneal or lens surfaces (1)
  - Increased intraocular pressure, acute angle-closure glaucoma (1)
  - Formation of synechiae
  - Cataract formation (1)
  - Vasculitis with vascular occlusion, retinal infarction
  - Macular edema (1)
  - Optic nerve damage

## Codes

**&NA;**

### ICD10

- H20.9 Unspecified iridocyclitis
- H30.90 Unspecified chorioretinal inflammation, unspecified eye
- H20.019 Primary iridocyclitis, unspecified eye

## Clinical Pearls

**&NA;**

- Symptoms vary depending on depth of involvement and associated conditions but should be suspected when eye pain is associated with visual changes.
- Severe or unresponsive uveitis may require therapy, including periocular injection of corticosteroids, sustained-release corticosteroid implants, systemic corticosteroids, cytotoxic agents, immunosuppressive agents, immunomodulatory agents, or tumor necrosis factor inhibitors.

# Vaginal Adenosis

Maeve K. Hopkins, MA, MD

Michael P. Hopkins, MD, MEd

## BASICS

### DESCRIPTION

- The normal vagina is lined with squamous epithelium. Adenosis is characterized by the presence of columnar epithelium or glandular tissue in the wall of the vagina.
- Around week 15 of embryologic development, the müllerian system, which forms the upper 2/3 of the vagina, fuses with the invaginating cloaca or urogenital sinus to form the lower 1/3 of the vagina. Squamous metaplasia from the cloacal region then produces squamous epithelium within the vagina (1).
- Adenosis occurs when this squamous epithelium fails to epithelialize the vagina completely.
- Three main types of adenosis epithelium described
  - Endocervical
  - Endometrial
  - Tubal
- System(s) affected: reproductive

### Geriatric Considerations

- Adenosis is a disorder of the young female. By menopause, the vagina and cervix should be completely epithelialized.
- The presence of glandular epithelium in the postmenopausal patient is an indication for excision and close evaluation for the possibility of a well-differentiated adenocarcinoma.

### Pregnancy Considerations

Pregnancy produces a wide eversion of the transformation zone of the cervix. This occasionally will become so widely everted that it will extend onto the vaginal fornices, leading to the impression of adenosis. This will resolve after the pregnancy is completed.

# EPIDEMIOLOGY

## *Incidence*

- Although the cumulative incidence of vaginal adenosis is unknown, the incidence of cloacal malformations is 1/20,000 to 1/25,000 live births.
- Although spontaneous vaginal adenosis appears to be fairly common (10% of adult women), it is mostly an insignificant coincidental finding. Widespread symptomatic involvement is rare (2).

## *Prevalence*

- In the United States, adenosis is relatively common; affecting 10-20% of young females studied. As maturation progresses with puberty, epithelialization occurs.
- Predominant age
  - Age <1 month: 15%
  - Prepubertal: typically absent
  - Age 13 to 25 years: 13%
  - Age >25 years: decreasing prevalence, uncommon beyond age 30 years (2)

# ETIOLOGY AND PATHOPHYSIOLOGY

- In most young females, the etiology is incomplete squamous metaplasia or epithelialization. This occurs as a natural phenomenon and resolves with age.
- Described as congenital or acquired (2)
  - Congenital: proliferation of the remnant müllerian epithelium in the vagina due to exposure to diethylstilbestrol (DES) in utero (DES daughters)
  - Transformation-related protein 63 (TRP63/p63) marks the cell fate decision of müllerian duct epithelium to become squamous epithelium in the cervix and vagina. DES disrupts the TRP63 expression and induces adenosis lesions (3). It has also been suggested that DES induces vaginal adenosis by inhibiting the BMP4/Activin A-regulated vaginal cell fate decision through a downregulation of RUNX1 (4).
  - Acquired: trauma and inflammation causing spontaneous de novo changes or changes in an acquired lesion in the vaginal epithelium
  - Additional reports have documented adenosis occurring subsequent to sulfonamide-induced Stevens-Johnson syndrome and after treatment of vaginal condylomas with 5-fluorouracil (5).

## RISK FACTORS

Adenosis of the vagina/cervix may arise in up to 90% of DES daughters, and there is a 40-fold increased risk of the subsequent development of clear cell adenocarcinoma (6).

## GENERAL PREVENTION

None: last DES exposure in the 1970s

## COMMONLY ASSOCIATED CONDITIONS

DES exposure

- Adenosis from DES exposure should lead to an evaluation of other DES-related abnormalities.
- Müllerian tract anomalies associated with DES exposure include cervical hood, cervical ridge, shortened cervix, incompetent cervix, and T-shaped uterine cavity.
- Patients with known DES exposure should have their reproductive tract evaluated prior to conception.
- Most patients with adenosis have not been DES-exposed and do not require evaluation of the reproductive system.
- DES is a synthetic, nonsteroidal estrogen that was used to prevent spontaneous abortions or premature deliveries from 1938 to 1971 (6). An estimated 5 million women were prescribed DES during this period (3).
- The FDA issued a drug bulletin in 1971 advising physicians to stop prescribing DES to pregnant women because of its link to vaginal clear cell adenocarcinoma in DES daughters (6).

## DIAGNOSIS

### HISTORY

- Maternal DES exposure
- Complaints of
  - Profuse mucoid vaginal discharge from the glandular epithelium
  - Pruritus
  - Pain/soreness of the vaginal introitus
  - Postcoital bleeding
  - Dyspareunia

## PHYSICAL EXAM

On pelvic exam, adenosis appearance is varied: patchy or diffuse red stippling, granularity or nodularity, single or multiple cysts, erosions, ulcers, or warty protuberances that may even extend to the vulva.

## ***DIFFERENTIAL DIAGNOSIS***

- Erosive lichen planus
- Fixed drug eruption
- Erythema multiforme
- Bullous skin disease
- Adenocarcinoma
  - A thorough evaluation for adenocarcinoma of the vagina arising in adenosis should be done.
  - A biopsy may be necessary to ensure that the process represents only benign adenosis.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

Four-quadrant Pap smear should be used liberally to isolate quadrants of the vagina that may contain abnormalities. No imaging is indicated, unless diagnosed with underlying malignancy.

### ***Follow-Up Tests & Special Considerations***

Pap smear can be followed by colposcopy and biopsy.

---

P.1099

### ***Diagnostic Procedures/Other***

Colposcopy should be used to outline areas of adenosis to ensure that no malignancy is present.

### ***Test Interpretation***

- Biopsy will show benign glandular epithelium.
- Biopsies in the areas of ongoing squamous metaplasia are typical (7).

## **TREATMENT**

### ***GENERAL MEASURES***

- Unless malignancy is present, conservative treatment is indicated.

- In most young females with this condition, it will resolve with expectant management (2).
- Treatment is warranted in women with severe subjective symptoms that impair the quality of life (8).
- For patients with focal lesions and no history of DES exposure, simple excision appears to be an effective modality of treatment (5)

## ***ISSUES FOR REFERRAL***

Malignancy found on biopsy warrants referral to gynecologic oncology specialist.

## ***SURGERY/OTHER PROCEDURES***

- Aggressive therapy, such as laser or surgical excision, is necessary if premalignant or malignant changes arise (4).
- Symptomatic treatment with carbon dioxide laser coagulation, unipolar coagulation, or, lastly, vaginal resection (2)

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Outpatient management

## **ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

### ***Patient Monitoring***

If the initial colposcopy is normal, a yearly fourquadrant Pap smear of the vagina and of the cervix is all that is necessary.

### ***DIET***

No special diet

## ***PATIENT EDUCATION***

- No limitations
- It is not necessary to avoid intercourse or placing objects in the vagina.
- The patient should be educated to keep normal guideline-recommended pelvic and Pap smear

appointments. In most situations, this is benign, and expectant management is all that is necessary.

- <http://www.acog.org/>

## PROGNOSIS

- It is expected that most patients will have squamous metaplasia and epithelialization with complete resolution of the adenosis.
- The rare patient, 1/1,000 to 1/10,000, may develop adenocarcinoma in the adenosis and will require definitive therapy as for vaginal cancer.
  - Cumulative incidence of progression of adenosis to adenocarcinoma is 1.5/1,000 for DES daughters (6).

## COMPLICATIONS

- Infertility with DES association
- Adverse pregnancy outcome with DES association
- Adenocarcinoma of vagina
- Clear cell adenocarcinoma with DES association

Vaginal Malignancy

## Codes

&NA;

## ICD10

- Q52.4 Other congenital malformations of vagina
- N89.8 Other specified noninflammatory disorders of vagina
- T38.5X5A Adverse effect of other estrogens and progestogens, initial encounter

## Clinical Pearls

**&NA;**

- Adenosis is characterized by the presence of columnar epithelium or glandular tissue in the wall of the vagina.
- Adenosis is more common among the daughters of women exposed to DES.
- Adenosis is rarely associated with an underlying vaginal malignancy.

# Vaginal Bleeding During Pregnancy

Virginia Van Duyne, MD

## BASICS

### DESCRIPTION

- Vaginal bleeding during pregnancy has many causes and ranges in severity from benign with normal pregnancy outcome to life-threatening for both infant and mother.
- Etiology can be from the vagina, cervix, uterus, fetus, or placenta. The differential diagnosis is guided by the gestational age of the fetus.

### EPIDEMIOLOGY

#### Prevalence

- In early pregnancy: 7-25% of patients
- In late pregnancy: 0.3-2% of patients

### ETIOLOGY AND PATHOPHYSIOLOGY

- Many times the cause is unknown.
- Anytime in pregnancy:
  - Cervicitis (infectious or noninfectious)
  - Vaginal or cervical trauma (including postcoital)
  - Cervical lesion or neoplasia
  - Hyperemia of cervix (increased blood flow from pregnancy)
- Early pregnancy:
  - For up to 50% of early pregnancy bleeding, no cause is ever found.
  - Ectopic pregnancy: leading cause of 1st-trimester maternal death in the United States. Risk factors: previous ectopic, trauma to fallopian tubes (tubal surgery, infection, tumor), congenital anomaly of tubes, in utero diethylstilbestrol (DES) exposure, current use of IUD, history of infertility, tobacco use

- Spontaneous abortion: risk factors: advanced maternal age (AMA), alcohol use, tobacco use, anesthetic gas, heavy caffeine use, cocaine use, chronic maternal diseases (poorly controlled diabetes mellitus [DM], celiac disease, autoimmune diseases such as antiphospholipid syndrome), short interconception time (3 to 6 months), current use of IUD, maternal infection (e.g., herpes simplex virus [HSV], gonorrhea, chlamydia, toxoplasmosis, listeriosis, HIV, syphilis, malaria), medications (e.g., retinoids, methotrexate, NSAIDs), multiple previous therapeutic abortions, previous spontaneous abortion, toxins (arsenic, lead, polyurethane), uterine abnormalities (congenital, adhesions, fibroids)
- Implantation bleeding: benign, about 6 days after fertilization
- Uterine fibroids
- Subchorionic bleed: in late 1st trimester
- Low-lying placenta
- Gestational trophoblastic disease: hydatidiform mole (most common), choriocarcinoma, or placental-site trophoblastic tumors
- Late pregnancy:
  - Bloody show of labor (mucus plug)
  - Placenta previa: painless bleeding; occurs in 0.4% deliveries in the United States. Risk factors: previous history of placenta previa, previous uterine surgery (cesarean section, D&C), chronic hypertension, multiparity, multiple gestation, tobacco use, AMA
  - Placental abruption: painful bleeding; occurs in 1-2% deliveries in the United States. Risk factors: previous placental abruption, 1st-trimester bleeding, hypertension, preeclampsia, multiple gestation, tobacco, cocaine or methamphetamine use, unexplained elevated maternal  $\alpha$ -fetoprotein, poly- or oligohydramnios, AMA, trauma to abdomen, premature rupture of membranes, thrombophilia, short umbilical cord, male fetus, chorioamnionitis, nutritional deficiency
  - Vasa previa: minimal bleeding with fetal distress; rare (1:2,500 deliveries). Risk factors: in vitro fertilization, multiple gestation, placental abnormalities (low-lying position, bilobate, succenturiate lobe, velamentous insertion of umbilical cord)
  - Placenta accreta, increta, percreta: risk factors: uterine scar (e.g., from cesarean section, endometrial ablation or D&C), current placenta previa, AMA, tobacco use, multiparity, uterine anomalies, uterine fibroids, hypertension
  - Uterine rupture: vaginal bleeding, abnormal fetal heart rate, and disordered or hypertonic uterine contractions with or without pain. Risk factors: previous cesarean section (most common), trauma, use of oxytocin or prostaglandins, multiparity, external cephalic version, placental abruption, shoulder dystocia, placenta percreta, Müllerian duct anomalies, history

of pelvic radiation

## **RISK FACTORS**

See specific etiologies in earlier discussion.

## **GENERAL PREVENTION**

- Address modifiable risk factors such as domestic violence and tobacco and drug use.
- If placenta or vasa previa, nothing per vagina

## **DIAGNOSIS**

### **HISTORY**

- Anytime in pregnancy: quality of pregnancy dating, context (e.g., following bowel movement, during voiding, after intercourse, drug use, or trauma including domestic violence), amount of bleeding, obstetrical history, personal or family history of inherited bleeding disorders
- Early pregnancy: severe nausea/vomiting (can be associated with molar pregnancy); amount of bleeding, pelvic pain, or suprapubic cramping (e.g., spontaneous abortion, ectopic) complications in previous pregnancies (e.g., spontaneous abortion, abruption, 1st-trimester vaginal bleeding)
- Late pregnancy: contractions (labor), abdominal pain especially between contractions (abruption, uterine rupture), presence or absence of fetal movement, rupture of membranes
- See “Etiology and Pathophysiology” for additional pertinent history.

### **PHYSICAL EXAM**

- Vital signs: When present, signs of hemodynamic instability are first tachycardia and tachypnea, then hypotension and thready pulse.
- Abdomen: uterine tenderness, fundal height (increasing fundal height may be associated with placental abruption)
- Speculum: Visualize cervix and identify source of bleeding (from cervical os or from within vagina).
- Cervix: assess for dilation; required to assess for labor but should not be performed until placenta previa ruled out via ultrasound
- Fetal monitoring: Doppler heart tones in early pregnancy; external fetal monitoring for

gestational age >26 weeks

## ***DIFFERENTIAL DIAGNOSIS***

- Hematuria (UTI, kidney stones)
- Rectal bleeding

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- CBC
- Blood type and screen; if significant hemorrhage, type and cross-match
- Quantitative *β*-human chorionic gonadotropin (*β*-hCG):
  - Prior to 12 weeks, levels can be followed serially every 2 days with following trends:
    - Doubles or at least 66% rise in 48 hours in normal pregnancy
    - Falls in spontaneous abortion
    - Extremely high in molar pregnancy
    - Rises gradually (<50% in 48 hours) or plateaus in ectopic pregnancy
- Transvaginal ultrasound should be used to confirm an intrauterine pregnancy (IUP) when the quantitative *β*-hCG >2,000 (1)[A].
- Other lab tests based on clinical scenario:
  - Wet mount, gonorrhea/chlamydia, Pap smear
  - Progesterone level occasionally used to determine viability in threatened abortion (<5 indicates not viable, >25 indicates viability, 5 to 25 is equivocal).
  - Bleeding time, fibrinogen, and fibrin split products: if suspect coagulopathy or abruption
  - Kleihauer-Betke: low sensitivity and specificity for abruption; helpful for dosing Rho(d) immune globulin (RhoGAM)
- Ultrasound is the preferred imaging modality.
  - Early pregnancy:
    - Gestational sac seen at 5 to 6 weeks; fetal heartbeat observed by 8 to 9 weeks
    - Diagnostic of ectopic with nearly 100% sensitivity when *β*-hCG level 1,500 to 2,000 mIU/mL. If no IUP is present and ultrasound does not confirm ectopic pregnancy, serial

quantitative  $\beta$ -hCG values should be followed (2)[C].

- Late pregnancy:
  - Proceed to rule out placenta previa with ultrasound, labor with serial cervical exams, and abruption with external fetal monitoring.

## **ALERT**

Confirm fetal presentation and placental position prior to cervical exam.

P.1101

## **TREATMENT**

### *MEDICATION*

#### *First Line*

- Treat underlying cause of bleeding, if identified.
- If mother is Rh negative, give RhoGAM to prevent autoimmunization. In late pregnancy, dose according to the amount of estimated fetomaternal hemorrhage.
- If cause of bleeding is preterm labor, consider betamethasone for fetal lung maturity if <34 weeks' gestation. Tocolytics may be used to prolong pregnancy to allow for course of steroids.
- If threatened abortion: Consider progesterone (relative risk 0.53) (3)[A].
- If mother has an inherited bleeding disorder or if bleeding is severe, consider recombinant or donor blood products.

### *SURGERY/OTHER PROCEDURES*

- Cesarean section may be indicated for recurrent or uncontrolled bleeding with placenta or vasa previa.
- If ectopic is diagnosed, immediate surgical treatment may be needed. Some early ectopic pregnancies can be treated medically if certain criteria are met (2)[C].
- Surgical uterine evacuation is necessary for molar pregnancy due to malignant potential (4)[C].
- Incomplete or inevitable spontaneous abortion: Management is patient centered. In the absence of infection, patient may elect expectant, medical, or surgical management. If expectant management, typically wait 2 weeks for patient to complete abortion; most complete by 9 days. If at 2 weeks abortion is not completed or medical management has failed, surgical intervention (D&C or aspiration) is generally indicated (5)[A]. May send tissue

to pathology to confirm.

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

- In early pregnancy: based on quantity of bleeding, need for surgical treatment for ectopic pregnancy, or presence of infection in case of spontaneous abortion
- In late pregnancy, if significant bleeding and/or presence of maternal or fetal compromise
- In late pregnancy with trauma, if  $\geq 2$  contractions/10 minutes

### ***Discharge Criteria***

- In late pregnancy, may discharge when bleeding has stopped; labor, previa, and abruption have been ruled out; and fetal heart tracing is normal.
- After trauma in late pregnancy, may discharge home if normal fetal heart tracing for  $\geq 4$  hours with  $< 2$  contractions/10 minutes

## **ONGOING CARE**

### ***Patient Monitoring***

- Patient should be instructed to report any increase in the amount or frequency of bleeding and to seek immediate care if experiencing fever, abdominal pain, or sudden increased bleeding. Patient should save any tissue passed vaginally for examination.
- Frequency of outpatient follow-up as indicated based on etiology of bleeding

## **PATIENT EDUCATION**

- American Academy of Family Physicians (AAFP): [www.familydoctor.org](http://www.familydoctor.org)
- American College of Obstetricians & Gynecologists (ACOG): [www.acog.org](http://www.acog.org)

## **PROGNOSIS**

- Prognosis depends on the etiology of vaginal bleeding, severity of bleeding, and rapidity of diagnosis.
- Maternal mortality is 31.9 deaths/100,000 ectopic pregnancies.
- 1/2 of patients with early pregnancy bleeding miscarry. If fetal heart activity (ultrasound) present in 1st-trimester bleed,  $< 10\%$  chance of pregnancy loss.

- Heavy bleeding in early pregnancy, particularly when accompanied by pain, is associated with higher risk of spontaneous abortion. Spotting and light episodes are not, especially if lasting only 1 to 2 days.
- Subchorionic hemorrhage has about 2- to 3-fold increased risk of spontaneous abortion. Smaller hemorrhage and presence of viable fetal heart rate confer lower risk of loss. Most resolve spontaneously.
- Women with early pregnancy bleeding have an increased risk of preterm delivery, premature rupture of membranes, manual removal of placenta, placental abruption, elective cesarean delivery, and term labor induction later in the same pregnancy. These women also have an increased risk of adverse pregnancy outcomes, including hyperbilirubinemia, congenital anomalies, NICU admission, and reduced neonatal birth weight. Finally, there is an increased risk in subsequent pregnancies of recurrence of early pregnancy bleeding.
- Bed rest has not been shown to affect the outcome of bleeding in early pregnancy but may be indicated for bleeding in late pregnancy with placenta or vasa previa or with maternal hypertension.

# Codes

**&NA;**

## ICD10

- O20.9 Hemorrhage in early pregnancy, unspecified
- O46.90 Antepartum hemorrhage, unspecified, unspecified trimester
- O20.0 Threatened abortion

## Clinical Pearls

**&NA;**

- Obtain blood type and screen all women presenting with vaginal bleeding in pregnancy and administer RhoGAM to all Rh-negative patients.
- For up to 50% of early pregnancy bleeding, no cause is ever found.
- Always consider ectopic pregnancy in 1st-trimester bleeding.
- Do not perform digital exam in late pregnancy bleeding until placenta has been located on ultrasound.

# Vaginal Malignancy

Jay R. Patibandla, MD

Michael P. Hopkins, MD, MEd

## BASICS

### DESCRIPTION

- Carcinomas of the vagina are uncommon: 3% of gynecologic malignancies, 2,300 new cases annually.
- Vaginal intraepithelial neoplasia (VAIN), defined by squamous cell atypia, is classified by the depth of epithelial involvement:
  - VAIN 1: 1/3 thickness
  - VAIN 2: 2/3 thickness
  - VAIN 3 and carcinoma in situ (CIS): >2/3 with CIS, designating full-thickness neoplastic changes without invasion through the basement membrane
- Invasive malignancies: Vaginal malignancies include squamous cell carcinoma (85-90%), adenocarcinoma (5-10%), sarcoma (2-3%), and melanoma (2-3%). Clear cell carcinoma is a subtype of adenocarcinoma. Invasive squamous cell carcinoma has the potential for metastasis to the lungs and liver.
- To be classified as a vaginal malignancy, only the vagina can be involved. If the cervix or vulva is involved, then the tumor is classified as a primary cancer arising from the cervix or the vulva.
- Most vaginal malignancies are metastatic (e.g., cervix, vulva, endometrium, breast, ovary).

### *Pregnancy Considerations*

This malignancy is not associated with pregnancy.

### EPIDEMIOLOGY

#### *Incidence*

- An estimated 4,070 new cases will be diagnosed in 2015 with 910 resulting deaths (1).

## Predominant age

- CIS: mid-40 to 60 years
- Invasive squamous cell malignancy: mid-60 to 70 years
- Adenocarcinoma: any age; 50 years is the mean age. Peak incidence is between 17 and 21 years of age.
- Clear cell adenocarcinoma occurs most often in females <30 years with a history of exposure to diethylstilbestrol (DES) in utero.
- Mixed müllerian sarcomas and leiomyosarcomas in the adult population: mean age 60 years

## *Pediatric Considerations*

Vaginal tumors are extremely rare. Rhabdomyosarcoma (botryoid and embryonal subtype) is the most common malignant neoplasm of the vagina. Less common entities are germ cell tumor and clear cell adenocarcinoma.

## *Prevalence*

In the United States, it is one of the rarest of all gynecologic malignancies (3%).

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Women with a history of cervical malignancy have a higher probability of developing squamous cell malignancy in the vagina even after hysterectomy.
- Human papillomavirus (HPV) is found in 80-93% of patients with vaginal CIS and 50-65% of the patients with invasive vaginal carcinoma (2,3).
- HPV-16 is the most common, found in 66% of CIS and 55% of invasive vaginal cancers.
- Smokers have a higher incidence.
- Clear cell adenocarcinoma of the vagina in young women has been associated with DES exposure. The incidence, however, is exceedingly rare, estimated at 1/1,000 to 1/10,000 exposed females.
- Metastatic lesions can involve the vagina, spreading from the other gynecologic organs.
- Although rare, renal cell carcinoma, lung adenocarcinoma, GI cancer, pancreatic adenocarcinoma, ovarian germ cell cancer, trophoblastic neoplasm, and breast cancer can all metastasize to the vagina.

## *Genetics*

No known genetic pattern

## **RISK FACTORS**

- Similar risk factors as cervical cancer
- Age
- African American
- Smoking
- Multiple sex partners, early age of first sexual intercourse
- History of squamous cell cancer of the cervix or vulva
- HPV infection
- Vaginal adenosis
- Vaginal irritation
- DES exposure in utero

## **COMMONLY ASSOCIATED CONDITIONS**

Due to the field effect, patients with vaginal cancer are more likely to develop malignancy in the cervix or vulva and should be followed closely.

## **DIAGNOSIS**

### **HISTORY**

- Abnormal bleeding is the most common symptom.
- Postcoital bleeding can result from direct trauma to the tumor.
- Vaginal discharge
- Dyspareunia
- Urinary symptoms, including hematuria and increased frequency
- Constipation
- Pain along with symptoms and signs of hydronephrosis are late findings when the tumor has spread into the paravaginal tissues and extends to the pelvic sidewall.

### ***Pediatric Considerations***

In children, sarcomas can present either as a mass protruding from the vagina or as abnormal genital bleeding.

# PHYSICAL EXAM

## Pelvic examination

- The vagina, uterus, adnexa (fallopian tubes and ovaries), bladder, and rectum should be evaluated for unusual changes.
- Vaginal malignancies are found most commonly on the posterior wall in the upper 1/3 of the vagina.

# DIFFERENTIAL DIAGNOSIS

- Premalignant changes: VAIN 1, 2, 3, and CIS
- Adequate biopsies ensure that invasive lesions are not overlooked. Invasive lesions penetrate the basement membrane and cannot be treated conservatively.
- Other malignancies, such as endometrial, cervix, bladder, or colon cancer, can invade directly into the vagina or metastasize to the vagina.
- In the childbearing years, trophoblastic disease should be considered.
  - The vagina is a common site of metastases; however, biopsy should typically be avoided because the implants are very vascular and may hemorrhage if sampled.
  - The clinical presentation is typically obvious so histopathologic confirmation before treatment is not required.

# DIAGNOSTIC TESTS & INTERPRETATION

## Initial Tests (lab, imaging)

- Pap smear may incidentally detect asymptomatic lesions.
- Biopsy suspicious lesions
- Chest x-ray (CXR): to evaluate for metastatic disease
- CT scan and MRI: to evaluate the liver and retroperitoneum, especially the lymph nodes in the pelvic and periaortic area
- PET scan detects primary and secondary metastatic lesions more often than CT scan.

## **ALERT**

PET scan correlation with CT scan lesions strongly suggests malignancy.

## Follow-Up Tests & Special Considerations

- Lymphoscintigraphy (sentinel lymph node mapping) as part of the pretreatment evaluation can

result in a change in the radiation fields and improve comprehensive treatment planning in women with vaginal cancer.

- HPV vaccination: Implementation of prophylactic HPV vaccination could prevent  $\div 2/3$  of the intraepithelial lesions in the lower genital tract but is yet unproven.

### *Diagnostic Procedures/Other*

- Colposcopy with directed biopsies for small lesions
- Wide excision under anesthesia of superficial disease may be necessary to ensure that invasive cancer is not present.
- Cystoscopy to rule out bladder invasion
- Proctosigmoidoscopy to rule out rectal invasion

### *Test Interpretation*

Tumors are staged clinically:

- Stage 0: VAIN and CIS
- Stage I: carcinoma limited to the vaginal wall (26%)
- Stage II: involves the subvaginal tissues but has not extended to the pelvic wall (37%)
- Stage III: extends to the pelvic wall (24%)
- Stage IV: extends beyond the true pelvis (13%)
  - IVa: Tumor invades bladder and/or rectal mucosa and/or direct extension beyond the true pelvis.
  - IVb: spread to distant organs

## **TREATMENT**

### *GENERAL MEASURES*

Treatment methods for VAIN and CIS include the following:

- Wide local excision
- Partial or total vaginectomy

- 
- Intravaginal chemotherapy with 5% fluorouracil cream

- Laser therapy
- Intracavitary radiation therapy

## *MEDICATION*

- Imiquimod
  - In a review of the effectiveness of 5% imiquimod cream in the treatment of VAIN, the following results were reported (4)[C]:
    - 26-100% of patients had complete regression.
    - 0-60% of patients had partial regression.
    - 0-37% experienced recurrence.
- Contraindications
  - The diagnosis must be established with certainty prior to treatment.
  - If there is any doubt that a process beyond in situ disease exists, vaginectomy must be performed. These patients are often elderly, and aggressive therapy is limited by the patient's performance status and ability to tolerate radical surgery, chemotherapy, or radiation.

## *ISSUES FOR REFERRAL*

Patients should be treated by a gynecologic oncologist and/or a radiation oncologist.

## *ADDITIONAL THERAPIES*

- Treatment with radiotherapy depends on the stage of disease. This treatment option should be discussed with physicians experienced with this malignancy.
- It is common to use radiotherapy and chemotherapy (chemoradiation) for better cancer control.
- Early-stage primary squamous cell carcinoma treated with radiation alone has shown good results (5)[A].
- Stage III vaginal cancer may benefit from combined radiation and hyperthermia (6)[C].
- Patients with advanced squamous cell carcinoma or adenocarcinoma receive concurrent irradiation and cisplatin-based chemotherapy (7)[B].
- Neoadjuvant chemotherapy followed by radical surgery may benefit select patients (8)[C].
- In most tumor types, metastatic disease from the vagina to other sites is only minimally

responsive to chemotherapy.

- With one exception, no chemotherapeutic agents have shown a survival advantage. The exception is childhood sarcomas, which have been treated with combinations of the following:
  - Vincristine
  - Dactinomycin (actinomycin-D)
  - Cyclophosphamide (Cytosan)
  - Cisplatin
  - Etoposide (VP-16)

## ***SURGERY/OTHER PROCEDURES***

- Whenever there is a doubt as to the presence or absence of invasive disease, vaginectomy must be performed.
- Invasive lesions usually are treated by radiation therapy, but stage I lesions can be treated with radical hysterectomy or radical vaginectomy with pelvic lymph node dissection (9)[A].
- If the lesion involves the lower vagina, inguinal node dissection also must be done because cancer involving the lower vagina can metastasize to the groin region.
- Premenopausal women who desire to retain ovarian function are better candidates for radical surgery for early-stage disease, with vaginal reconstruction possible afterward.
- Patients who have not completed their family can occasionally be treated with limited resection and localized radiation to the area.
- Sarcomas are treated by radiation therapy followed by pelvic exenteration if persistent disease is present.

### ***Pediatric Considerations***

The treatment of vaginal tumors today mainly consists of neoadjuvant chemotherapy followed by local control with surgery or radiotherapy.

### ***Geriatric Considerations***

Older patients, many with a long history of smoking, are at a higher risk for malignancies requiring surgical treatments.

**ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

- Patients are usually ambulatory and able to resume full activity by 6 weeks after surgery.
- Most patients are fully active while receiving chemotherapy and radiation therapy.

### ***Patient Monitoring***

- Pelvic examination and Pap smear every 3 months for 2 years, then every 6 months for the next 3 years and then yearly thereafter
- Annual CXR

## ***PATIENT EDUCATION***

- Printed patient information available from American College of Obstetricians and Gynecologists, 409 12th St., SW, Washington, DC 20024-2188; 800-762-ACOG: <http://www.acog.org>
- American Cancer Society: <http://www.cancer.gov>
- Medline Plus: <http://www.nlm.nih.gov/medlineplus/vaginalcancer.html>

## ***PROGNOSIS***

Stage and 5-year survival (10)

- I: 77.6%
- II: 52.2%
- III: 42.5%
- IVA: 20.5%
- IVB: 12.9%

## **COMPLICATIONS**

- Those typically associated with major abdominal surgery or radiation therapy
- Common complications of treatment include rectovaginal or vesicovaginal fistulas, rectal/vaginal strictures, radiation cystitis, and/or proctitis.

## Codes

**&NA;**

### **ICD10**

- C52 Malignant neoplasm of vagina
- D07.2 Carcinoma in situ of vagina
- N89.3 Dysplasia of vagina, unspecified

## **Clinical Pearls**

**&NA;**

- Vaginal cancer is rare; 85-90% of vaginal cancers are squamous cell.
- Vaginal malignancies are found most commonly on the posterior wall in the upper 1/3 of the vagina.
- Most vaginal malignancies are metastatic (from cervix, vulva, endometrium, breast, or ovary).

# Vaginitis and Vaginosis

Heather O'Connor Greer, MD

Patricia Beauzile, MD

## BASICS

### DESCRIPTION

- Vaginosis and Vaginitis are broad terms indicating any disease process of the vagina caused by or leading to infection, inflammation, or changes in the normal vaginal flora.
- The difference between vaginitis and vaginosis is the presence (vaginitis) or absence (vaginosis) of inflammation.
- The most common symptoms of vaginitis/vaginosis are vaginal discharge, odor, itching, burning, or pain.
- The most common causes of vaginitis are bacterial vaginosis (BV), vulvovaginal candidiasis (VVC), and trichomoniasis.
- Other causes of vaginitis can be stratified by age and are generally associated with postmenopausal vaginal atrophy or foreign bodies in the pediatric population.
- Lichen planus, lichen sclerosus, and psoriasis, may also cause vaginitis.
- Diagnosis of vaginitis relies on thorough history, physical exam, and clinical assessment. Microscopy, cultures, DNA probes, and tissue biopsy can be helpful in confirming diagnosis.
- BV is the most common cause of vaginal discharge in reproductive-aged women. It is caused by a disturbance in the normal vaginal flora. The normally dominant hydrogen-peroxide producing lactobacilli are overwhelmed by an overgrowth of gram-negative species causing an increase in the vaginal pH, discharge, and odor.
- VVC is the second most common cause of vaginitis in reproductive-aged women. It is caused by invasion of the *Candida* organism into the superficial epithelial cells of the vagina causing mild to severe vaginal inflammation, pruritis, and discharge.

### EPIDEMIOLOGY

- Vaginal symptoms are typical and common in the general population and are one of the most frequent reasons women present to their medical care providers accounting for approximately 10 million office visits each year (1).

- About 30% of women with complaint of vaginal discharge or irritation remain undiagnosed despite extensive testing.
- In the United States, BV continues to be the leading cause of vaginal complaints.
- The frequency of VVC is highest among women in their reproductive years (2).
- Neither vaginal candidiasis nor BV is considered to be sexually transmitted diseases.
- Vaginal trichomoniasis is a common sexually transmitted disease with 7.4 million cases diagnosed yearly in the United States (3).

## ETIOLOGY AND PATHOPHYSIOLOGY

- BV (4)
  - BV is caused by a change in the normal vaginal flora. Dominant lactobacilli responsible for maintaining the acidic vaginal pH are overcome by an increase of the gram-negative organisms.
  - Change in the vaginal environment leads to an increase in the pH and an overgrowth of vaginal anaerobes causing a malodorous discharge and frothy vaginal discharge.
  - BV is highly prevalent and associated with multiple adverse outcomes, including enhanced HIV transmission.
  - The organisms generally implicated in BV infections include:
    - *Gardnerella vaginalis*
    - *Prevotella* species
    - *Porphyromonas* species
    - *Bacteroides* species
    - *Peptostreptococcus* species
    - *Mycoplasma hominis*
    - *Ureaplasma urealyticum*
    - *Mobiluncus* species
    - *Fusobacterium* species
    - *Atopobium vaginae*
- VVC
  - VVC is caused by *Candida albicans* (80-92%) and *C. glabrata* (<10%)

- Candida organisms can be identified in the lower genital tract in healthy women, and it is thought to gain access via rectal and perianal colonization and migration.
- Symptoms occur when candidal organisms overwhelm the normal vaginal flora and invade the superficial vaginal epithelial cells causing inflammation, pruritis, and thick vaginal discharge.
- Trichomoniasis
  - Caused by an infection via *Trichomonas vaginalis*, a flagellate protozoan. The organism infects the squamous epithelium of the vagina, as well as the urethra, and paraurethral glands. This infection is primarily transmitted during sexual intercourse.
  - Other sources of vaginitis/vaginosis are usually mediated by disruption of the vaginal squamous epithelium. This disruption can lead to inflammation, pain, and discharge.
  - Other than the three most common causes of vaginitis/vaginosis, menses, sexual activity, contraception, pregnancy, foreign bodies, estrogen levels, STDs, and use of vaginal hygiene products, topical creams, or antibiotics can contribute to vaginal symptoms

## RISK FACTORS

- BV:
  - Sexual activity; while BV is not considered an STD, studies show increased rates of BV in women with multiple sex partners
  - Women who have sex with women
  - The presence of STDs such as HSV-2 (5)
- VVC:
  - Diabetes
  - Use of broad-spectrum antibiotics.
  - Immunosuppression
  - Higher estrogen levels have been associated with increased vaginal yeast infection, explaining why it is more commonly diagnosed in reproductive aged women and in pregnancy.
- Trichomoniasis:
  - Inconsistent use of barrier contraception
  - Multiple sex partners
  - African Americans

- Limited education and low socioeconomic status
- Other risk factors associated with vaginitis/vaginosis:
  - Decreased estrogen
  - Smoking
  - Use of vaginal douches and creams.
  - Tight fitting clothing
  - Poor hygienic practice
  - Changes in diet

## *GENERAL PREVENTION*

- Vulvar hygiene
- Treatment of sexual partners generally is not recommended but may be considered in recurrent cases.

## *COMMONLY ASSOCIATED CONDITIONS*

- STDs such as gonorrhea, chlamydia, or HSV
- Vaginal intraepithelial neoplasia and cancer can present with symptoms of vaginitis.
- Desquamative inflammatory vaginitis presents with similar symptoms but most commonly occurs in postmenopausal women.

## **DIAGNOSIS**

### **HISTORY**

- General principles:
  - The key to diagnosis is clarification of the presenting symptoms.
  - Onset, timing, and character of the vaginal symptoms are important questions to ask.
  - Many patients will be asymptomatic, and diagnosis is made on routine physical exam and lab testing.
  - Symptomatic patients generally complain of itching, burning, irritation, and abnormal discharge.
- BV

- Symptomatic patients complain of abnormal vaginal discharge and a fishy odor.
- VVC
  - Symptomatic women report itching, burning, irritation, dyspareunia, burning with urination, and a white thick discharge.
- Trichomoniasis
  - Symptomatic patients will complain of abnormal discharge, itching, burning, or postcoital bleeding.

## *PHYSICAL EXAM*

- BV
  - Thin watery, sometimes foamy discharge. Can appear beige- or tan-colored. An amine or fishy smell may be present on exam.
  - The vaginal epithelium should appear normal and noninflamed.
- VVC
  - Erythema and swelling of the vulva and vaginal mucosa
  - Some patients may have vulvar excoriation and fissures.
  - If discharge is present, it is usually white, thick, and can have a cottage cheese appearance. Some women may have thin white dilute discharge. No odor is present.
- Trichomoniasis
  - Significant erythema of the vulva and vaginal mucosa
  - Greenish discharge with an amine or fishy odor
  - Discharge can also appear purulent in some patients.
  - Occasionally punctate hemorrhages can be seen on the vaginal walls and on the cervix (strawberry cervix).

## *DIFFERENTIAL DIAGNOSIS*

- Physiologic discharge
- Leukorrhea of pregnancy
- STDs

Foreign body

- Contact dermatitis
- Cervicitis
- Desquamative inflammatory vaginitis
- Urinary tract infection (UTI)
- Atrophic vaginitis
- Dermatoses: lichen sclerosus, lichen planus, seborrheic dermatitis, psoriasis

---

P.1105

## **DIAGNOSTIC TESTS & INTERPRETATION**

- BV
  - Symptomatic patients complain of an abnormal vaginal discharge and a fishy odor.
  - Clinical diagnosis is established with Amsel criteria. A positive diagnosis can be made if 3 out of 4 of the following criteria are present (6)[B].
    - Gray, frothy, or foamy discharge
    - Vaginal pH >4.5
    - A positive amine or Whiff test with use of KOH solution added to discharge
    - >20% of the epithelial cells identified as Clue cells
- VVC
  - Visualization of blastospores or pseudohyphae on saline or 10% KOH microscopy
  - A positive culture in a symptomatic patient
- Trichomoniasis
  - Visualization of motile trichomonads on saline microscopy (7)[B]

## **TREATMENT**

### **GENERAL MEASURES**

- Avoid douching and tight fitting clothing.
- Regular use of condoms and spermicides may help to prevent BV.

## MEDICATION

- BV
  - Metronidazole 500 mg orally BID for 7 days, vaginally 0.75% gel 1 applicator daily for 5 days, or clindamycin given vaginally (1 applicator = 100 mg) for 5 days (8)[A]. Recurrent infection may require repeated treatment (e.g., 1 week monthly for 6 months).
- VVC
  - Uncomplicated infections can be treated with a one time dose of fluconazole 150 mg tab. Topical/vaginal suppository antifungal regimens such as butoconazole, clotrimazole, miconazole, terconazole, or nystatin creams. Treatment can range from 3 to 7 days (7)[A].
  - Recurrent or complicated infections may require additional oral dosing of fluconazole 150 mg tab for extended treatment and/or prophylaxis (9)[A].
- Trichomoniasis
  - A one time 2 g oral dose of either tinidazole or metronidazole. Alternatively, 500 mg dose of metronidazole twice daily for 7 days (10)[A].
  - The patient's partner should be treated as well and counseled to abstain from sex until both patients have completed treatment.

## ISSUES FOR REFERRAL

Treating male partners does not reduce symptoms or prevent recurrence, but can be considered in patients with recurrent infection.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

A Cochrane analysis reviewed the use of probiotics for BV and found inconclusive evidence to recommend probiotics as primary treatment or as a preventive strategy (11)[A]. Further study was recommended.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

- Delay sexual relations until symptoms clear/discomfort resolves
- Use of condoms may reduce recurrence of BV.

### Patient Monitoring

- No specific follow-up needed; if symptoms persist or recur within 2 months, repeat pelvic exam and culture.
- Consider suppressive therapy for recurrent infection.

## PATIENT EDUCATION

American College of Obstetricians and Gynecologists (ACOG), 409 12th St., SW, Washington, DC 20024-2188; 800-762-ACOG: [www.acog.org](http://www.acog.org)

## PROGNOSIS

VVC: 80-90% of uncomplicated cases cured with appropriate treatment; 30-50% of recurrent infections return after discontinuation of maintenance therapy; there is a relatively high spontaneous remission rate of untreated symptoms as well.

## COMPLICATIONS

- VVC may occur following treatment of BV.
- BV has been associated with an increased risk of acquisition and transmission of HIV.
- BV has been associated with increased risk of preterm birth, chorioamnionitis, postpartum and postabortal endometritis, and pelvic inflammatory disease.

**See Also**

**&NA;**

Algorithm: Discharge, Vaginal

## Codes

**&NA;**

### ICD10

- N76.0 Acute vaginitis
- B37.3 Candidiasis of vulva and vagina
- N95.2 Postmenopausal atrophic vaginitis

## Clinical Pearls

**&NA;**

Clinical symptoms, signs, and microscopy have relatively poor performance compared with so-called gold standards such as culture and DNA probe assays, but these more sensitive assays can detect organisms that may not be causing symptoms.

- Most women experience relief of symptoms with therapy chosen without such gold standard tests, even when the treatment does not correspond with the underlying infection.
- Vaginal pH is underused as a diagnostic tool for evaluation of vaginitis.

# Varicose Veins

Joseph A. Florence, MD

Leigh D. Johnson, MD

## BASICS

### DESCRIPTION

- Superficial venous disease causing a permanent dilatation and tortuosity of superficial veins, usually occurring in the legs and feet; caused by systemic weakness in the vein wall and may result from congenitally incomplete valves or valves that have become incompetent
- Affects legs where reverse flow occurs when dependent
- Truncal varices involve the great and small saphenous veins; branch varicosities involve the saphenous vein tributaries.
- Categorized as the following:
  - Uncomplicated (cosmetic)
  - With local symptoms (pain confined to the varices, not diffuse)
  - With local complications (superficial thrombophlebitis, may rupture causing bleeding)
  - Complex varicose disease (diffuse limb pain, swelling, skin changes/ulcer)
- System(s) affected: cardiovascular; skin

### ALERT

Ulceration of varicose veins has a high rate of infection, which can lead to sepsis.

### *Geriatric Considerations*

- Common; usually valvular degeneration but may be secondary to chronic venous deficiency
- Elastic support hose and frequent rests with legs elevated rather than ligation and stripping

### *Pregnancy Considerations*

- Frequent problem

- Elastic stockings are recommended for those with a history of varicosities or if prolonged standing is involved.

## *EPIDEMIOLOGY*

### *Incidence*

- Predominant age: middle age
- Predominant gender: female > male (2:1)
- National Women's Health Information Center estimates that 50% of women have varicose veins.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Varicose veins are caused by venous insufficiency from faulty valves in <sup>31</sup> perforator veins in the lower leg, causing secondary incompetence at the saphenofemoral junction (valvular reflux).
- Valvular dysfunction causing venous reflux and subsequently venous hypertension (HTN)
- Failed valves allow blood to flow in the reverse direction (away from the heart), from deep to superficial and from proximal to distal veins.
- Deep thrombophlebitis
- Increased venous pressure from any cause
- Congenital valvular incompetence
- Trauma (consider arteriovenous fistula; listen for bruit)
- Presumed to be due to a loss in vein wall elasticity with failure of the valve leaflets
- An increase in venous filling pressure is sufficient to promote varicose remodeling of veins by augmenting wall stress and activating venous endothelial and smooth muscle cells (1).

### *Genetics*

Autosomal dominant with incomplete penetrance

## *RISK FACTORS*

- Increasing age
- Pregnancy, especially multiple pregnancies
- Prolonged standing

- Obesity
- History of phlebitis (postthrombotic syndrome)
- Family history
- Female sex
- Increased height
- Congenital valvular dysfunction

## COMMONLY ASSOCIATED CONDITIONS

- Stasis dermatitis
- Large varicose veins may lead to skin changes and eventual stasis ulceration.

## DIAGNOSIS

### HISTORY

- Symptoms range from minor annoyance/cosmetic problem to a lifestyle-limiting problem.
- Localized symptoms: pain, burning, itching
- Generalized symptoms
  - Leg muscular cramp, aching
  - Leg fatigue/swelling
- Pain if varicose ulcer develops
- Symptoms often worse at the end of the day, especially after prolonged standing.
- Women are more prone to symptoms due to hormonal influences: worse during menses.
- No direct correlation with the severity of varicose veins and the severity of symptoms

### PHYSICAL EXAM

- Inspect lower extremities while the patient is standing. Varicose veins in the proximal femoral ring and distal portion of the legs may not be visible when the patient is supine.
- Varicose veins are the following:
  - Dilated, tortuous, superficial veins, chiefly in the lower extremities

- Dark purple/blue in color, raised above the surface of the skin
- Often twisted, bulging, and can look like cords
- Most commonly found on the posterior/medial lower extremity
- Edema of the affected limb may be present.
- Skin changes may include the following:
  - Eczema
  - Hyperpigmentation
  - Lipodermatosclerosis
- Spider veins (idiopathic telangiectases)
  - Fine intracutaneous angiectasis
  - May be extensive/unsightly
- Neurologic sensory and motor exam
- Peripheral arterial vasculature; pulses
- Musculoskeletal exam for associated rheumatologic/orthopedic issues

## *DIFFERENTIAL DIAGNOSIS*

- Nerve root compression
- Arthritis
- Peripheral neuritis
- Telangiectasia: smaller, visible blood vessels that are permanently dilated
- Deep vein thrombosis
- Inflammatory liposclerosis

## *DIAGNOSTIC TESTS & INTERPRETATION*

Duplex ultrasound: Noninvasive imaging duplex ultrasound will confirm the etiology, anatomy, and pathophysiology of segmental venous reflux. The severity of both symptoms and signs tends to correlate with the degree of venous reflux, which is identified by duplex ultrasound as retrograde or reversed flow of greater than 0.5 second duration (2).

## *Diagnostic Procedures/Other*

Duplex scanning, venous Doppler study, photoplethysmography, light-reflection rheography, air plethysmography, and other vascular testing should be reserved for patients who have venous symptoms and/or large (>4 mm in diameter) vessels or large numbers of spider telangiectasia indicating venous HTN.

## *Test Interpretation*

A clinical classification illustrating the current physical state is useful in clinical practice (1).

- 0: no visible or palpable signs of venous disease
- 1: spider veins or telangiectasias
- 2: varicose veins
- 3: edema
- 4: skin changes (pigmentation, eczema, lipodermatosclerosis, atrophie blanche)
- 5: healed ulcer
- 6: active ulcer

## **TREATMENT**

- Conventional wisdom suggests conservative therapy (e.g., elevation, external compression, weight loss) as being helpful; while compression stockings improve the severity of varicose veins, they do not seem to improve quality of life (3)[B].
- There is insufficient, high-quality evidence to determine whether or not compression stockings are effective as the sole and initial treatment of varicose veins in people without healed or active venous ulceration, or whether any type of stocking is superior to any other type (4)[A].
- All the current modalities of endoluminal and open surgical treatment have similar short-term outcomes and risks (5)[A].
- Appropriate surgical treatment has the best longterm outcomes and evidence base (5)[A].
- Treatment of choice, however, depends on many factors, including local expertise (5)[A].
- When comparing quality of life, pain relief, and long-term relief, surgery is favored (6)[A].
- Endovenous laser ablation (EVLA); radiofrequency ablation, foam sclerotherapy, and surgical stripping for great saphenous varicose veins are all efficacious (7)[A].
- Endovenous ablation (radiofrequency and laser) is at least as effective as surgery in the treatment of great saphenous varicose veins and outcomes remain similar at 2 years (8)[A]; however, ultrasoundguided foam sclerotherapy has insufficient support from available data (7)

[A].

- The ambulatory conservative hemodynamic correction of venous insufficiency method (cure conservatrice et hémodynamique de l'insuffisance veineuse en ambulatoire [CHIVA]) is a less-invasive approach based on venous hemodynamics with deliberate preservation of the superficial venous system. The CHIVA method reduces recurrence of varicose veins and produces fewer side effects than vein stripping (9)[A].

## GENERAL MEASURES

Patients with unsightly varicose veins often seek treatment for cosmetic reasons.

---

P.1107

## MEDICATION

Superficial thrombophlebitis is not an infective condition and does not require antibiotic treatment.

## ISSUES FOR REFERRAL

- Emergency: bleeding from a varicosity that has eroded the skin
- Urgent: varicosity that has bled and is at risk for bleeding again
- Soon: ulcer that is progressive/painful despite treatment
- Routine
  - Active/healed ulcer/progressive skin changes that may benefit from surgery
  - Recurrent superficial thrombophlebitis
  - Troublesome symptoms attributable to varicose veins or patient and provider feel that the extent, site, and size of the varicosities are having a severe impact on quality of life.

## ADDITIONAL THERAPIES

- Apply elastic stockings before lowering legs from the bed.
- Activity
  - Frequent rest periods with legs elevated
  - If standing is necessary, frequently shift weight from side to side.
  - Appropriate exercise routine as part of conservative treatment
  - Walking regimen after sclerotherapy is important to help promote healing.
  - Never sit with legs hanging down.

- Physical therapy

## ***SURGERY/OTHER PROCEDURES***

- Surgery
  - Improved quality-adjusted life-years and symptoms compared to conservative management at 2 years (1)[A]
  - Surgery is indicated if there is pain, recurrent phlebitis, or skin changes/ulceration or for cosmetic improvement for severe cases.
  - Minimally invasive techniques include the following:
    - Radiofrequency ablation (RFA): compared with surgery provides a faster return to work; less pain, better short-term quality of life; less bruising and tenderness compared with endovenous laser therapy (1)[A]
    - Endovenous microwave ablation (EMA) is an effective new technique for the treatment of varicose veins and had a more satisfactory clinical outcome than high ligation and stripping (HLS) in the short term (10)[A].
    - EVLA is as effective as conventional surgery (CS) and superior to ultrasound-guided foam sclerotherapy (UGFS), according to occlusion on ultrasound duplex (11)[B].
    - Quality of life improves after treatment in all groups (EVLA, CS, UGFS), significantly (11) [B].
    - There is no significant difference between EVLA and open surgery in patients with great saphenous vein incompetence (12)[A].
- Sclerotherapy is a simple, safe, and particularly effective for smaller, early varicosities and also for residual veins after surgery (13)[C].
- Radiotherapy
  - RFA takes longer to perform but has better early outcome than CS in patients with great saphenous varicose veins.
  - Radiofrequency and laser treatments replace stripping; however, most varicosities still require phlebectomy/sclerotherapy.

## **ONGOING CARE**

### ***DIET***

- No special diet
- Weight-loss diet is recommended if obesity is a problem.

## *PATIENT EDUCATION*

- Avoid long periods of standing and crossing legs when sitting.
- Exercise (walking, running) regularly to improve leg strength and circulation.
- Maintain an appropriate weight.
- Wear elastic support stockings.
- Avoid clothing that constricts legs.
- Surgery/sclerotherapy may not prevent development of varicosities, and the procedure may need to be repeated in later years.
- National Heart, Lung and Blood Institute, Communications and Public Information Branch, National Institutes of Health, Building 31, Room 41-21, 9000 Rockville Pike, Bethesda, MD 20892; 301-496-4236. <http://www.nhlbi.nih.gov/>
- JAMA Patient Page| Treatment of Varicose Veins; <http://jama.jamanetwork.com/article.aspx?articleid=1672241>

## *PROGNOSIS*

- Usual course: chronic
- Favorable with appropriate treatment
- Surgery has a nonsignificant reduction in the risk of varicose vein recurrence compared with liquid sclerotherapy and endoluminal interventions (6)[A].
- Increasing disease severity by venous clinical severity score (VCSS) is associated with reductions in quality of life (14)[B].

## **COMPLICATIONS**

- Complications with sclerotherapy include hyperpigmentation, matting, local urticaria, cutaneous necrosis, microthrombi, accidental intra-arterial injection, phlebitis, deep vein thrombosis, thromboembolism, scintillating scotomas, nerve damage, and allergic reactions.
- Petechial hemorrhages
- Chronic edema
- Superimposed infection
- Varicose ulcers

- Pigmentation
- Eczema
- Recurrence after surgical treatment
- Scarring/nerve damage from stripping technique
- Neurologic complications after sclerotherapy are rare (6)[B].

## Codes

&NA;

### ICD10

- I83.90 Asymptomatic varicose veins of unspecified lower extremity
- I83.009 Varicose veins of unsp lower extremity w ulcer of unsp site
- I83.10 Varicose veins of unsp lower extremity with inflammation

## Clinical Pearls

&NA;

- Long-term safety and efficacy of surgery for the treatment of varicose veins is supported by low-quality evidence. Less-invasive treatments, which are associated with less periprocedural

disability and pain, are supported by short-term studies (4)[A].

- Endovascular treatment of varicose veins is safe and effective and has a rapid recovery (7)[A]. Insufficient evidence exists to prefer sclerotherapy over surgery (6)[A].
- The efficacy of sclerotherapy is not significantly affected by the choice of sclerosant, dose, formulation (foam vs. liquid), local pressure dressing, or degree and length of compression (6)[A].

# Vasculitis

Irene J. Tan, MD, FACR

## BASICS

### DESCRIPTION

An inflammatory blood vessel disorder

- Clinical features result from the destruction of blood vessel walls with subsequent thrombosis, ischemia, bleeding, and/or aneurysm formation.
- Vasculitis consists of a large, heterogeneous group of diseases classified by the predominant size, type, and the location of involved blood vessels (1).
  - Small-vessel vasculitis
    - Microscopic polyangiitis (MPA)
    - Granulomatosis with polyangiitis (GPA, formerly Wegener granulomatosis)
    - Eosinophilic granulomatosis with polyangiitis (EGPA; formerly Churg-Strauss syndrome)
    - Antiglomerular basement membrane disease (anti-GBM)
    - Cryoglobulinemic vasculitis
    - IgA vasculitis (Henoch-Schönlein purpura [HSP])
    - Hypocomplementemic urticarial vasculitis
  - Medium-vessel vasculitis
    - Polyarteritis nodosa (PAN)
    - Kawasaki disease (KD)
  - Large-vessel vasculitis
    - Takayasu arteritis (TAK)
    - Giant cell arteritis (GCA)
- Vasculitis occurs as a primary disorder or secondary to infection, a drug reaction, malignancy, or connective tissue disease.

- Variable vessel vasculitis
    - Behçet disease
    - Cogan syndrome
  - Single-organ vasculitis
    - Cutaneous leukocytoclastic angiitis
    - Cutaneous arteritis
    - Primary CNS vasculitis
  - Vasculitis associated with systemic disease
    - Lupus vasculitis
    - Rheumatoid vasculitis
    - Sarcoid vasculitis
  - Vasculitis associated with other etiology
    - Hepatitis C-associated cryoglobulinemic vasculitis
    - Hepatitis B-associated vasculitis
    - Syphilis-associated aortitis
    - Drug-induced immune complex vasculitis
    - Drug-associated antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitis
    - Cancer-associated vasculitis
- Protean features often delay definitive diagnosis.

## ***EPIDEMIOLOGY***

Highly variable, depending on the particular syndrome

- Hypersensitivity vasculitis is the most commonly encountered vasculitis in clinical practice.
- KD, IgA vasculitis, and dermatomyositis are more common in children.
- TAK is most prevalent in young Asian women. GPA, MPA, and EGPA are more common in middle-aged males.
- GCA occurs exclusively in those >50 years of age and is rare in the African American population.

## *Incidence*

Annual incidence in adults (unless otherwise specified)

- IgA vasculitis: 200 to 700/1 million in children <17 years of age
- GCA: 170/1 million
- KD: depends on race/age;  $\div$ 170/1 million
- PAN: 2 to 33/1 million
- GPA: 4 to 15/1 million
- MPA: 1 to 24/1 million
- EGPA: 1 to 3/1 million
- TAK: 2/1 million
- Hypersensitivity vasculitis: depends on drug exposure
- Viral-/retroviral-associated vasculitis: unknown; >90% of cases of cryoglobulinemic vasculitis are associated with hepatitis C.
- Connective tissue disorder-associated vasculitis: variable

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Three major immunopathogenic mechanisms
  - Immune-complex formation: systemic lupus erythematosus (SLE), IgA vasculitis (HSP), and cryoglobulinemic vasculitis
  - ANCA: GPA, MPA, and EGPA
  - Pathogenic T-lymphocyte response: GCA and TAK
- Pathophysiology best understood where known drug triggers have been identified (e.g., antibiotics, sulfonamides, and hydralazine)

## *Genetics*

- A number of the vasculitic syndromes have been linked to candidate genes.
- No single gene has been found to cause vasculitis.
- Angiotensin-converting enzyme insertion/deletion polymorphism is associated with susceptibility to vasculitis, especially in Behçet disease and IgA vasculitis.

## *RISK FACTORS*

A combination of genetic susceptibility and environmental exposure likely triggers onset.

## GENERAL PREVENTION

Early identification is the key to prevent irreversible organ damage in severe forms of systemic vasculitis.

## COMMONLY ASSOCIATED CONDITIONS

Hepatitis C (cryoglobulinemic vasculitis), hepatitis B (PAN), cytomegalovirus (CMV), Epstein-Barr virus (EBV), HIV (viral-/retroviral-associated vasculitis), SLE, rheumatoid arthritis (RA), Sjögren syndrome, mixed connective tissue disease (MCTD), dermatomyositis, ankylosing spondylitis, Behçet disease, relapsing polychondritis (CTD-associated vasculitis), respiratory tract methicillin-resistant *Staphylococcus aureus* (MRSA) (GPA)

## DIAGNOSIS

### HISTORY

- Consider age, gender, and ethnicity.
- Comprehensive medication history
- Family history of vasculitis
- Constitutional symptoms: fever, weight loss, malaise, fatigue, diminished appetite, sweats
- CNS/PNS: mononeuritis multiplex, polyneuropathy, headaches, visual loss, tinnitus, stroke, seizure, encephalopathy
- Heart/lung: myocardial infarction, cardiomyopathy, pericarditis, cough, chest pain, hemoptysis, dyspnea
- Renal: hematuria
- GI: abdominal pain, hematochezia, perforation
- Musculoskeletal: arthralgia, myalgia
- Miscellaneous: unexplained ischemic or hemorrhagic events, chronic sinusitis, and recurrent epistaxis
- Note the organs affected and estimate the size of blood vessels involved.
- Demographics, clinical features, and the predominant vessel size/organ involvement help identify specific type of vasculitis.

## PHYSICAL EXAM

- Vital signs: blood pressure (hypertension) and pulse (regularity and rate)

- Skin: palpable purpura, livedo reticularis, nodules, ulcers, gangrene, nail bed capillary changes
- Neurologic: cranial nerve exam, sensorimotor exam
- Ocular exam: visual fields, scleritis, episcleritis
- Cardiopulmonary exam: rubs, murmurs, arrhythmias
- Abdominal exam: tenderness, organomegaly

## *DIFFERENTIAL DIAGNOSIS*

- Fibromuscular dysplasia
- Embolic disease (atheroma, cholesterol emboli, atrial myxoma, mycotic aneurysm with embolization)
- Drug-induced vasospasm (cocaine, amphetamines, ergots)
- Thrombotic thrombocytopenic disorders (disseminated intravascular coagulation [DIC], thrombotic thrombocytopenic purpura [TTP], antiphospholipid syndrome, heparin- or warfarin-induced thrombosis)
- Systemic infection (infective endocarditis, fungal infections, disseminated gonococcal infection, Lyme disease, syphilis, Rocky Mountain spotted fever [RMSF], bacteremia)
- Malignancy (lymphomatoid granulomatosis, angioimmunoblastic T-cell lymphoma, intravascular lymphoma)
- Miscellaneous (Goodpasture syndrome, sarcoidosis, amyloidosis, Whipple disease, congenital coarctation of aorta)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### **ALERT**

- Renal involvement is often clinically silent. Routine serum creatinine and urinalysis with microscopy are needed to identify underlying glomerulonephritis.

- Initial tests to exclude alternate diagnosis and guide appropriate therapy
- Routine tests
  - CBC
  - Liver enzymes
  - Serum creatinine

- Specific serology
  - Antinuclear antibodies (ANA)
  - Rheumatoid factor (RF)
  - Rapid plasma reagin/venereal disease reaction level (RPR/VDRL)
  - RMSF titer
  - Lyme titer
  - Complement levels C3, C4
  - ANCA
  - Antiproteinase 3 antibodies (anti-PR3)
  - Antimyeloperoxidase antibodies (anti-MPO)
  - Hepatitis screen for B and C
  - Cryoglobulin
  - Anti-GBM titer
  - HIV
  - Serum and urine protein electrophoresis
- Miscellaneous
  - Drug screen
  - ESR
  - C-reactive protein
  - Creatine kinase (CK)
  - Blood culture
  - ECG
- CXR, CT scan, MRI, and arteriography may be required to delineate extent of organs involved.

### *Diagnostic Procedures/Other*

- Electromyography with nerve conduction can document neuropathy and target nerve for biopsy.

- Biopsy of affected site confirms diagnosis (e.g., temporal artery, sural nerve, renal biopsy).
- If biopsy is not practical, angiography may be diagnostic for large- and medium-vessel vasculitides.
- Bronchoscopy may be required to differentiate pulmonary infection from potentially life-threatening hemorrhagic vasculitis in patients with hemoptysis.

## *Test Interpretation*

Blood vessel biopsy shows immune cell infiltration into vessel wall layers with varying degrees of necrosis and granuloma formation, depending on the type of vasculitis

## **TREATMENT**

### *GENERAL MEASURES*

- Discontinue offending drug (hypersensitivity vasculitis)
- Simple observation for mild cases of IgA vasculitis
- ANCA-associated vasculitis has 2-phase treatment: initial induction followed by maintenance (steady tapering of corticosteroids with immunosuppressants or immunomodulators)

### *MEDICATION*

#### *First Line*

Corticosteroids are initial anti-inflammatory of choice.

#### *Second Line*

Cytotoxic medications, immunomodulatory, or biologic agents (e.g., cyclophosphamide (2)[B], (3,4)[A] methotrexate (4,5)[A], azathioprine (4,5)[A], leflunomide (4)[A], mycophenolate mofetil (2)[B], (4)[A], and rituximab (3,4)[A], are often required in combination with corticosteroids for rapidly progressive vasculitis with significant organ involvement or inadequate response to corticosteroids.

### *ISSUES FOR REFERRAL*

- Rheumatology referral for complicated cases where newer or more toxic treatments are required.
- Nephrology referral for persistent hematuria or proteinuria, rising creatinine, or a positive ANCA titer

- Pulmonary referral for persistent pulmonary infiltrate unresponsive to antibiotic therapy or if gross hemoptysis

## ***ADDITIONAL THERAPIES***

- IVIG and aspirin for KD, but corticosteroids are contraindicated.
- Plasma exchange appears to improve recovery of patients with severe acute renal failure secondary to vasculitis and pulmonary hemorrhage (4)[A].

## ***SURGERY/OTHER PROCEDURES***

Rarely, corrective surgery is required to repair tissue damage as a result of aggressive vasculitis.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Hemoptysis, acute renal failure, intestinal ischemia, any organ-threatening symptoms or signs, and/or need for biopsy
- Initial therapy is guided by the organ system involved.
  - If pulmonary hemorrhage is present, life-saving measures may include mechanical ventilation, plasmapheresis, and immunosuppression.
  - If acute renal failure is present, attend to electrolyte and fluid balance and consider plasma exchange and immunosuppression.
  - If signs of intestinal ischemia are present, make NPO and consider plasmapheresis, immunosuppression, and parenteral nutrition.

### ***Discharge Criteria***

Stabilization or resolution of potential life-threatening symptoms

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

If significant coronary artery disease is involved in KD, moderate activity restriction may be of benefit.

### ***Patient Monitoring***

Frequent clinical follow-up supported by patient selfmonitoring to identify disease relapse

## DIET

Alter diets for patients with renal involvement or hyperglycemia/dyslipidemia

## PROGNOSIS

Prognosis is good for patients with vasculitis and limited organ involvement. Relapsing courses, renal, intestinal, or extensive lung involvement have a poorer prognosis.

## COMPLICATIONS

- Persistent organ dysfunction may be the result of the disease, medications, or inflammation/scarring in the more serious forms of vasculitis.
- Early morbidity/mortality is due to active vasculitic disease; delayed morbidity/mortality may also be secondary to complications of chronic therapy with cytotoxic medications.

## Codes

&NA;

### ICD10

- I77.6 Arteritis, unspecified
- M31.30 Wegener's granulomatosis without renal involvement
- M30.0 Polyarteritis nodosa

## Clinical Pearls

&NA;

- Suspect vasculitis in patients with a petechial rash, palpable purpura, glomerulonephritis, pulmonaryrenal syndrome, intestinal ischemia, or mononeuritis multiplex.
- Exclude silent renal involvement by routinely obtaining serum creatinine and urinalysis with microscopy.
- Vasculitis has ØskipÓ lesions, which may complicate diagnostic biopsy.
- In patients with vasculitis, look for a primary underlying process such as infection, thrombosis, or malignancy.

# Venous Insufficiency Ulcers

Barbara J. Provo, MSN, RN, FNP-BC, CWON

Shahriar Alizadegan, MD

## BASICS

- Venous insufficiency disorders include simple spider veins, varicose veins, and leg edema.
- In the United States, 23% of adults have varicose veins, an estimated 22 million women and 11 million men.
- Venous leg ulcers are the most serious consequence of venous insufficiency.
- Venous leg ulcers are a type of chronic wound affecting up to 1% of adults in developed countries at some point during their lives.
- 500,000 people in the United States have chronic venous ulcers, with an estimated treatment cost of >\$3 billion per year.

## DESCRIPTION

- Full-thickness skin defect with surrounding pigmentation and dermatitis
- Most frequently located in ankle region of lower leg (Gaiter region)
- Present for >30 days and fails to heal spontaneously
- May only have mild pain unless infected
- Other signs of chronic venous insufficiency include edema/brawny edema and chronic skin changes (i.e., hyperpigmentation and/or fibrosis).

## EPIDEMIOLOGY

Up to 80% of leg ulcers are caused by venous disease; arterial disease accounts for 10-25%, which may coexist with venous disease.

### *Incidence*

- Overall incidence of venous ulcers is 18/100,000 persons.
- Prevalent sex: women > men (20.4 vs. 14.6 per 100,000 for venous ulcer); increased with age for both sexes

## *Prevalence*

- Seen in  $\div$ 1% of adult population in industrialized countries, increased to 5% in patients <sup>380</sup> years old
- Prevalence studies only available for Western countries
- Point prevalence underestimates the extent of the disease because ulcers often recur.
- 70% of ulcers recur within 5 years of closure.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- In a diseased venous system, venous pressure in the deep system fails to fall with ambulation, causing venous hypertension.
- Venous hypertension comes from the following:
  - Venous obstruction
  - Incompetent venous valves in the deep or superficial system
  - Inadequate muscle contraction (e.g., arthritis, myopathies, neuropathies) so that the calf pump is ineffective
- Venous pressure transmitted to capillaries leading to venous hypertensive microangiopathy and extravasation of RBCs and proteins (especially fibrinogen)
- Increased RBC aggregation leads to reduced oxygen transport, slowed arteriolar circulation, and ischemia at the skin level, contributing to ulcers.
- Leukocytes aggregate to hypoxic areas and increase local inflammation.
- Factors promoting persistence of venous ulcers
  - Prolonged chronic inflammation
  - Bacterial infection, critical colonization

## *RISK FACTORS*

- History of leg injury
- Obesity
- Congestive heart failure (CHF)
- History of deep venous thrombosis (DVT)
- Failure of calf muscle pump (e.g., ankle fusion, inactivity) is a strong independent predictor of poorly healing wounds.

- Previous varicose vein surgery
- Family history

## GENERAL PREVENTION

- Primary prevention after symptomatic DVT: Prescribe compression hose to be used as soon as feasible for at least 2 years (20 to 30 mm Hg compression).
- Secondary prevention of recurrent ulceration includes compression, correction of the underlying problem, and surveillance. Circumstantial evidence from two RCTs showed those who stopped wearing compression hose were more likely to recur.
- Compression hose reduces rates of recurrence compared with no compression.
- Because most ulcers develop following some type of trauma, avoiding lower leg trauma may help to prevent ulceration.

## COMMONLY ASSOCIATED CONDITIONS

Up to 50% of patients have allergic reactions to topical agents commonly used for treatment.

- Contact sensitivity was more common in patients with stasis dermatitis (62% vs. 38%).
- Avoid neomycin sulfate in particular (including triple antibiotic ointment) (1)[A].

## DIAGNOSIS

A diagnosis of venous reflux or obstruction must be established by an objective test beyond the routine clinical examination of the extremity.

### HISTORY

- Family history of venous insufficiency and ulcers
- Recent trauma
- Nature of pain: achy (better with leg elevation)
- Wound drainage
- Duration of wound and over-the-counter (OTC) treatments already attempted
- History of DVTs (especially factor V Leiden mutation; strongly associated with ulceration)
- History of leg edema that improves overnight
- Edema that does not improve overnight is more likely lymphedema.

## PHYSICAL EXAM

- Look for evidence of venous insufficiency:
  - Pitting edema
  - Hemosiderin staining (red and brown spotty or diffuse pigment changes)
  - Stasis dermatitis
  - White skin lesions (atrophie blanche)
  - Lipodermatosclerosis (‘‘bottle neck’’ narrowing in the lower leg from fibrosis and scarring)
- Look for evidence of significant lymphedema (i.e., dorsal foot or toe edema, edema that does not resolve overnight or with elevation). This may require referral for special comprehensive lymph therapy.
- Examine for palpable pulses.

### ALERT

- Examine wound for the following:
  - Length, width, depth, to monitor wound healing rate
  - Presence of necrotic tissue
  - Presence of biofilms or infection: purulent material in the wound, increased amount odorous exudate, spreading cellulitis, fever, and chills
- Get initial and interim girth measurements (at ankle and midcalf) to monitor edema.
- Important to rule out poor arterial circulation:
  - Compression dressings cannot be used in patients with ankle brachial index (ABI) <0.8.

## DIFFERENTIAL DIAGNOSIS

- Arterial insufficiency ulcer
- Neuropathic ulcer
- Malignancy
- Sickle cell ulcer
- Vasculitic ulcer
- Calciphylaxis
- Cryoglobulinemia

- Pyoderma gangrenosum
- Collagen vascular disease
- Leishmaniasis
- Cutaneous tuberculosis

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Consider prothrombin time (PT)/international normalization ratio (INR) and partial thromboplastin time (PTT) if patient is anticoagulated.
- Consider biopsy of leg ulcers that fail to heal or have atypical features.
- Consider factor V Leiden mutation; strongly associated with venous ulcers.
- Test for diabetes as necessary with fasting glucose.
- Use duplex imaging to diagnose anatomic and hemodynamic abnormalities with venous insufficiency. It will also identify any DVT present.

## ***Diagnostic Procedures/Other***

- Check ABI for evidence of arterial disease.
- An ABI <0.8 is a relative contraindication to compression therapy.
- Duplex imaging for evaluation of superficial and deep venous reflux and incompetent perforator veins
- With concomitant severe arterial insufficiency, refer to a vascular surgeon for revascularization.

## ***Test Interpretation***

Strongly consider biopsy on wounds with atypical locations, failure to heal, or any suspicion of malignancy.

## **TREATMENT**

### ***GENERAL MEASURES***

Dressings: All wounds need some kind of a dressing underneath the compression system.

- Wound dressings: No single type of dressing proved superior (2)[B].
- Maintain semimoist wound environment: not excessively wet or dry.

- Wounds are often exudative until edema is decreased: Use absorptive dressings (calcium alginate or absorptive pads). Both superabsorbent diapers and female protection pads are cost-effective alternatives.
- Consider using barrier ointment/cream to prevent maceration of surrounding skin.
- If wound tends to be dry, use a hydrogel.
- A hydrocolloid dressing may be used with minimal exudate, if skin adhesive is tolerated.

## *MEDICATION*

- Effective compression management is the cornerstone of therapy.

P.1111

- Diuretics may help to reduce edema, but compression is the mainstay.
- Routine use of antibiotics for all venous ulcers is not recommended (1)[A],(3).
- Levamisole, not widely available, was the only systemic antibiotic with some evidence of benefit in terms of ulcer healing, versus treatment of infection (2)[B],(3).
- Evidence is insufficient for use of silver-based preparations and honey for healing wounds.
- Pentoxifylline 400 mg PO TID, in addition to local care and compression, improves cure rates. There is some response even without compression. GI side effects are common (4)[A].
- Aspirin 300 mg PO daily; effective when used with compression therapy

## *ISSUES FOR REFERRAL*

- With prominent toe or foot edema, consider lymphedema. Refer to a certified lymphedema therapist (CLT).
- Refer to a wound clinic for complex or poorly healing ulcers.
- Refer to a vein clinic or vascular specialist for recurrent ulcers.
- Use home health nurses to help with immobile patients needing frequent wrapping/dressing changes.

## *ADDITIONAL THERAPIES*

- Edema management: Reduce venous hypertension and improve venous return to reduce inflammation, pain, and improve healing (5)[A].
  - Compression therapy for edema management is the cornerstone of treatment for venous insufficiency with or without ulcers.
  - Short-stretch multilayer bandages are ideal for acute phase, until edema is stable, and the

patient can be fitted for compression hose.

- Long-term compression hose (fit once edema is reduced). Aim for a minimum pressure 20 to 30 mm Hg, preferably 30 to 40 mm Hg.
- Elevation of legs to heart level for 30 minutes 3 to 4 times per day.
- Exercise to strengthen calf muscle pump is also effective.
- Infection control
  - Debride necrotic tissue.
  - Treat cellulitis (usually gram-positive bacteria) with bactericidal systemic antibiotics. Suspect local infection when there is pain or no improvement in the wound after 2 weeks of compression. Consider deep quantitative swab, after thorough cleansing, or tissue biopsy for culture.
  - Treat critical colonization with topical antimicrobials, such as cadexomer iodine (silver dressings and honey are widely used, but definitive data are lacking) (3)[B].
- For venous ulcers resistant to healing with wound care and compression, consider adding an intermittent compression pump 1 to 4 hr/day.
- Encourage exercise (e.g., activation of calf muscle pump with ankle flexion and extension) in conjunction with leg compression and elevation.
- Vacuum-assisted closure (VAC) dressings may be beneficial, but no clear benefit over optimal traditional wound care.

## ***SURGERY/OTHER PROCEDURES***

- Necrotic tissue impedes healing.
  - Consider sharp debridement.
  - Other methods include enzymatic ointments (collagenase), low-frequency ultrasound, and wet-to-dry dressings.
  - Avoid using collagenase with silver dressings because silver inactivates the enzyme.
- Allografts made of synthetic skin bilayered with living keratinocytes and fibroblasts improve healing at 6 months; insufficient evidence to support use of autografts.
- In patients with ulcers refractory to conservative therapy, a variety of endovenous and surgical options exist. Consultation with a vascular surgeon is recommended.
- Endovenous ablation of incompetent superficial and perforator veins has shown to reduce the size and recurrence of ulcers in those who have failed conventional compression therapy (6)

[A].

- A subset of patients with nonhealing ulcers have stenosis and obstruction of the deep venous system. Venous angioplasty and stenting is emerging as an important adjunct to compression and other medical therapy (7)[A].

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Chestnut seed extract (50 mg BID) is effective for venous insufficiency but not ulceration.
- Topical medicinal honey used on wounds shows no evidence of improved healing.
- Oral zinc has not been shown to be beneficial

## **INPATIENT CONSIDERATIONS**

For those with acute significant cellulitis

### ***Admission Criteria/Initial Stabilization***

Infected wounds requiring IV antibiotics, especially in diabetics

## **ONGOING CARE**

- Venous insufficiency is a lifelong issue.
- After resolution of an ulcer, edema management must be maintained lifelong.

## **FOLLOW-UP RECOMMENDATIONS**

When ulcers are nearly healed and edema is controlled, switch from compression bandages to compression hose.

- Insurance may not reimburse for compression hose unless an ulcer is present.
- Referral for hose fitting must be done just prior to the ulcer being healed.

### ***Patient Monitoring***

Monitor the ulcer for healing by measuring its area. Expect at least 10% reduction every 2 weeks.

## **DIET**

- Obese patients may benefit from weight loss.
- Low-salt diets help fluid retention.

## PATIENT EDUCATION

Patient education for understanding of underlying mechanism is important for long-term management.

- Develop long-term plan for edema management and instruction on compression therapy.
- Instruct the patient on topical wound therapy.
- Teach early recognition and treatment of new ulcers or cellulitis.

## PROGNOSIS

- Ulcers recur frequently. Early identification and immediate treatment are essential.
- Ongoing diligence, with edema control, avoiding infections, and avoiding trauma are important.

## Codes

&NA;

### ICD10

- I87.2 Venous insufficiency (chronic) (peripheral)
- I83.009 Varicose veins of unsp lower extremity w ulcer of unsp site
- I89.0 Lymphedema, not elsewhere classified

## Clinical Pearls

&NA;

- Initial diagnostic workup should include venous duplex scan and arterial evaluation.
- Refer patients with ABI <0.8 to vascular surgery specialist.
- Refer patients with recurrent or poor healing venous ulcers to venous specialist or wound specialist.
- Compression is essential for edema management with or without wounds.

- Treat critical colonization with topical antimicrobials (avoid neomycin).
- Make sure that the diagnosis is correct, and biopsy when in doubt.

# Ventricular Septal Defect

Ian D. Thomas, MD

Brent J. Barber, MD

## BASICS

### DESCRIPTION

- Congenital or acquired defect of the interventricular septum that allows communication of blood between the left and the right ventricles
- Other than bicuspid aortic valve, it is the most common congenital heart malformation reported in infants and children. It also occurs as a complication of acute myocardial infarction (MI).
- Severity of the defect is correlated with its size, with large defects being the most severe.
- Blood flow across the defect typically is left to right, depending on defect size and pulmonary vascular resistance (PVR).
- Prolonged left to right shunting of blood can lead to pulmonary hypertension (HTN). This may eventually lead to a reversal of flow across the defect and cyanosis (Eisenmenger complex).

### *Geriatric Considerations*

Almost entirely associated with MI

### *Pediatric Considerations*

Congenital defect

### **ALERT**

- Pregnancy may exacerbate symptoms and signs of a ventricular septal defect (VSD).
- Can be tolerated during pregnancy if VSD is small
- May be associated with an increased risk of preeclampsia in women with an unrepaired VSD

### EPIDEMIOLOGY

## *Incidence*

- Congenital defect: no gender predilection, occurs in  $\div 2/1,000$  live births and accounts for 30% of all congenital cardiac malformations
- Post-MI: Males are affected more than females.

## *Prevalence*

In the United States:

- Congenital defect: lowered prevalence in adults due to spontaneous closure
- Post-MI: estimated to complicate 1-3%

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Congenital
- In adults, complication of MI

## *Genetics*

Multifactorial etiology; autosomal dominant and recessive transmissions have been reported.

## **RISK FACTORS**

- Congenital:
  - Risk of sibling being affected: 4.2%
  - Risk of offspring being affected: 4%
  - Prematurity
- Complication of MI:
  - First MI
  - HTN
  - Most frequently within first week after MI
  - Occurs in 1-3% of MIs, most commonly after anterior MI

## **GENERAL PREVENTION**

Avoid prenatal exposure to known risk factors (ibuprofen, marijuana, organic solvents, febrile illness). For adults, avoid risk factors for MI and obtain evaluation before pregnancy.

## COMMONLY ASSOCIATED CONDITIONS

- Congenital:
  - Tetralogy of Fallot
  - Aortic valvular deformities, especially aortic insufficiency and bicuspid aortic valve
  - Down syndrome (trisomy 21), endocardial cushion defect
  - Transposition of great arteries
  - Coarctation of aorta
  - Tricuspid atresia
  - Truncus arteriosus
  - Patent ductus arteriosus
  - Atrial septal defect
  - Pulmonic stenosis
  - Subaortic stenosis
- Adult: coronary artery disease

## DIAGNOSIS

### HISTORY

- Presentation depends on the degree of shunting across the defect; may be completely asymptomatic with small defects
- Respiratory distress, tachypnea, tachycardia
- Diaphoresis with feeds, poor weight gain in infants

### PHYSICAL EXAM

- Small defect:
  - Harsh holosystolic murmur loudest at left lower sternal border
  - Detected after PVR drops at 4 to 8 weeks of life
- Moderate defect:
  - Harsh holosystolic murmur at left lower sternal border associated with a thrill
  - Forceful apical impulse with lateral displacement

- Increased intensity of P<sub>2</sub>
- Diastolic rumble at apex due to increased flow across the mitral valve
- Large defect:
  - Holosystolic murmur heard throughout the precordium with diastolic rumble at apex with precordial bulge and hyperactivity, although large defects may have little or no murmur initially
  - If congestive heart failure (CHF) exists: tachycardia, tachypnea, and hepatomegaly
  - If pulmonary HTN exists: cyanosis with exertion
  - If Eisenmenger complex is present: cyanosis and clubbing

## *DIFFERENTIAL DIAGNOSIS*

- Any defect with left-to-right shunt, such as patent ductus arteriosus, atrial septal defect
- Children: tetralogy of Fallot
- Adults: mitral regurgitation

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- A 12-lead ECG may suggest severity of VSD. Initially, left ventricular hypertrophy and left atrial enlargement may be evident. As pulmonary HTN develops, right ventricular hypertrophy and right atrial enlargement may be seen.
- A chest x-ray (CXR) may demonstrate increased pulmonary vascularity and/or cardiomegaly.
- A 2D echocardiogram for visualization of location and size of defect
- Color flow Doppler for direction and velocity of VSD jet; may be used to estimate right ventricular pressure

### *Follow-Up Tests & Special Considerations*

- Weight and hematocrit check
- Cardiac catheterization performed occasionally for perioperative planning or to assess need for closure of defect

### *Diagnostic Procedures/Other*

Cardiac catheterization (left and right sides of heart) can confirm the diagnosis, document number of defects, quantify ratio of pulmonary blood flow to systemic blood flow ( $Q_p/Q_s$ ), and determine PVR.

- Demonstration of an oxygen saturation step up from the right atrium to the distal pulmonary artery

## *Test Interpretation*

- Congenital VSD (four major anatomic types)
  - Membranous (70%)
  - Muscular (20%)
  - Atrioventricular canal type (5%)
  - Supracristal (5%; higher in Asians)
- Post-MI VSD predominantly involves muscular septum.
- After surgical repair, right bundle branch block is common.

## **TREATMENT**

- Start diuretic therapy if overload signs are present (1)[A].
- Minimize IV fluids.
- Consider ACE inhibitor and/or digoxin.
- Nasogastric feeds for neonates
- Correct anemia via iron supplementation or a possible RBC transfusion.

## **GENERAL MEASURES**

- Appropriate health care maintenance
- Outpatient, until surgical repair is indicated
- Inpatient in setting of acute MI
- Inpatient for treatment of severe CHF

## **MEDICATION**

### *First Line*

- Per the 2007 American Heart Association guidelines, endocarditis antibiotic prophylaxis is not recommended for most VSDs. It is recommended for VSDs associated with complex cyanotic heart disease, during the first 6 months after surgical repair, or for residual VSDs located near the patch following surgery (2)[A]. However, recent reports suggest that patients with a left ventricle to right atrium VSD (Gerbode defect) may be at higher risk for endocarditis and thus may also need antibiotic prophylaxis (3)[C].
- Pediatric: Medications aim to control pulmonary edema, decrease work of breathing, and allow for growth:
  - Furosemide 1 to 2 mg/kg PO/IV once to twice a day
  - Spironolactone 1 to 2 mg/kg/day divided BID
  - Captopril
    - Infants: Oral: 0.3-2.5 mg/kg/day divided every 8-12 hours; max 2 mg/kg/day
    - Children and adolescents: Oral: 0.3-6 mg/kg/day divided every 8-12 hours; maximum daily dose: 150 mg/day

P.1113

- Digoxin: infants <2 years of age, 10 &mgr;g/kg/day PO divided BID; children, 2 to 10 years of age, 5 to 10 &mgr;g/kg/day PO divided BID; children >10 years of age, 2 to 5 &mgr;g/kg/day PO divided BID
- Adults: Digoxin and diuretics may be beneficial in some circumstances (1)[A].
- Side effects:
  - Drugs that increase systemic vascular resistance may increase left-to-right shunting and cause signs and symptoms of pulmonary overcirculation.
  - HTN

## Second Line

- Surgical closure is generally indicated if the pulmonic-to-systemic flow is >2:1 or with poorly controlled pulmonary overcirculation despite maximal medical and dietary interventions.
- If an infant with a VSD has persistent pulmonary HTN or failure to grow, surgical repair generally is recommended prior to 6 months of age even if patient is otherwise asymptomatic.
- For post-MI VSDs, afterload reduction, inotropic support, intra-aortic balloon pump, and left ventricular assist device may be used to stabilize the patient prior to surgery. Surgical repair includes septal debridement and patch placement.

## *ISSUES FOR REFERRAL*

Close follow-up of a congenital VSD is necessary until primary intracardiac repair is performed to ensure that significant pulmonary HTN does not develop.

## *ADDITIONAL THERAPIES*

- Infant caloric requirements up to 150 kcal/kg/day or more for adequate weight gain
- Treatment of iron deficiency anemia to increase oxygen-carrying capacity

## *SURGERY/OTHER PROCEDURES*

- Surgical correction with either a VSD patch or repair is commonly used. Postsurgical outcomes for isolated VSD are excellent. Complications are rare and include reoperation for residual VSD, extended hospital stay, arrhythmias, valve injury, depressed ventricular function, and heart block (4)[B].
- Percutaneous transcatheter device closure has become a safe and effective option for some children with small to moderate VSDs. Complications include valvular regurgitation, residual defects, and heart block. There is a greater risk of conduction abnormality with this technique compared to surgical closure. Recent studies have shown steroids may decrease this risk (5) [A].
- Periventricular device closure (hybrid technique) of some subtypes of isolated VSDs without cardiopulmonary bypass is feasible under transesophageal echocardiographic (TEE) guidance. Complications are similar to percutaneous closure (6)[A].

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Failure to thrive
- Pulmonary overcirculation/CHF
- Stabilize airway
- Reduce temperature stress

### *Nursing*

Frequent vital sign monitoring; daily weight and calorie counts

### *Discharge Criteria*

CHF stabilization, weight gain, or successful repair

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- Small VSDs without evidence of CHF or pulmonary HTN generally can be followed every 1 to 5 years after the neonatal period.
- Moderate to large VSDs require more frequent follow-up.
- Potential complications of VSDs include right ventricular outflow obstruction and aortic valve prolapse.

### *Patient Monitoring*

- Physical growth and development monitoring
- Influenza vaccine for children >6 months of age
- Palivizumab to children <12 months of age with hemodynamically significant lesions. Children with small VSDs do not need RSV prophylaxis (7)[A].

### *DIET*

- Low sodium in heart failure
- High calorie in failure to thrive

### *PATIENT EDUCATION*

- No activity restriction in absence of pulmonary HTN
- Parents need support and instructions for prevention of complications until the child is ready for surgery.

### *PROGNOSIS*

- Congenital:
  - Course is variable depending on the size of the VSD.
  - Small VSD: many will close spontaneously by age 3 years. Muscular defects are more likely to close spontaneously.
  - Large VSD: CHF or failure to thrive in infancy necessitating surgical repair.
  - 20-year cumulative survival rate after surgery for isolated VSD is 87%; 40 years is 78% (8).
  - Progressive pulmonary vascular disease and pulmonary HTN are the most feared

complications of VSD caused by left-to-right shunting and may eventually lead to reversal of the shunt (Eisenmenger complex). Death usually occurs in the 4th decade of life if untreated.

- Post-MI:
  - With medical management alone, 80-90% mortality in the first 2 weeks
  - Prognosis worse with inferior MI compared with anterior MI

## COMPLICATIONS

- CHF
- Aortic insufficiency
- Sudden death
- Hemoptysis
- Cerebral abscess
- Paradoxical emboli
- Cardiogenic shock
- Heart block rarely may accompany surgical closure.
- Pulmonary HTN

## Codes

&NA;

### ICD10

- Q21.0 Ventricular septal defect
- I23.2 Ventricular septal defect as current comp following AMI
- Q21.3 Tetralogy of Fallot

# Clinical Pearls

## &NA;

- A loud 2/6 to 3/6 low-pitched harsh holosystolic murmur at the left lower sternal border is typical.
- A diastolic rumble at the apex indicates moderate to large VSD or  $Q_p:Q_s >2:1$ , which likely will require surgical or percutaneous closure.
- Disappearance of the murmur could be secondary to spontaneous closure of the defect or the development of pulmonary HTN.
- Development of a new murmur of semilunar valve insufficiency should be further evaluated. Pulmonary regurgitation may occur as PVR increases, and the development of aortic regurgitation usually will require early surgery.

# Vertigo

Jeremy Raab, MD

James J. Arnold, DO, FAAFP

## BASICS

### DESCRIPTION

- A symptom, not a disease process. Among the potential causes are several life-threatening conditions. As such, the cause must be identified in order to determine the appropriate treatment.
- Sensation of movement (room spinning) when no movement is actually occurring; results from peripheral or central causes or may be induced by medications/anxiety disorders
- Important to distinguish between vertigo, presyncope (patient feels like they are going to black out; vision and hearing may become obscured), disequilibrium (off balance), and light-headedness (vague, inconsistent symptoms, no rotational component)
- System(s) affected: nervous
- Synonym(s): dizziness; acute vestibular neuritis; labyrinthitis; benign paroxysmal positional vertigo (BPPV)

### EPIDEMIOLOGY

#### Incidence

- Vertigo accounts for 54% of cases of dizziness reported in primary care; >90% of these patients are diagnosed with peripheral causes such as BPPV (1).
- Predominant sex: Female = male; women are more likely to experience central causes, particularly vertiginous migraine.

#### Geriatric Considerations

- Elderly patients with risk factors for cerebrovascular disease (CVD) are more likely to experience central causes.
- BPPV is commonly undiagnosed in the elderly and is an important risk factor for falls.

## Prevalence

- Ranges from 5 to 10% within the general population
- Lifetime prevalence for BPPV is 2.4%.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Dysfunction of the rotational velocity sensors of the inner ear results in asymmetric central processing. This is related to the combination of sensory disturbance of motion and malfunction of the central vestibular apparatus.
- Peripheral causes: Acute labyrinthitis, acute vestibular neuritis, BPPV (posterior canal 85-95%, lateral canal 5-15%), herpes zoster oticus, cholesteatoma, Ménière disease, otosclerosis, perilymphatic fistula, superior canal dehiscence syndrome, motion sickness; (1,2) BPPV, vestibular neuritis, and Ménière disease account for 93% of all vertigo (2).
- Central causes: cerebellar tumor, CVD, migraine, multiple sclerosis (1)
- Drug causes: psychotropic agents (antipsychotics, antidepressants, anxiolytics, anticonvulsants, mood stabilizers), aspirin, aminoglycosides, furosemide (diuretics), amiodarone,  $\alpha$ -blockers, nitrates, urologic medications, muscle relaxants, phosphodiesterase inhibitors (sildenafil), excessive insulin, ethanol, quinine, cocaine
- Other causes: cervical, psychological

## Genetics

Family history of CVD/migraines may indicate higher risk of central causes.

## RISK FACTORS

- History of migraines
- History of CVD/risk factors for CVD
- Use of ototoxic medications
- Trauma/barotrauma
- Perilymphatic fistula
- Heavy weight bearing
- Psychosocial stress/depression
- Exposure to toxins

## GENERAL PREVENTION

If due to motion sickness, consider pretreatment with anticholinergics, such as scopolamine.

## DIAGNOSIS

### HISTORY

- Determine if true vertigo or not by asking, “when you have dizzy spells, do you feel light-headed or do you see the world spin around you?” This reliably differentiates vertigo from nonvertiginous dizziness (1,2)[C].
- Obtain other medical and medication history: recent use of ototoxic medications (e.g., aminoglycosides); history of alcohol, nicotine, and caffeine use; sexual history; history of CVD/risk factors for CVD (1,3).
- Ask about duration of symptoms (2)[C].
  - A few seconds: peripheral cause such as unilateral loss of vestibular function; late stages of Ménière disease
  - Several seconds to a few minutes: BPPV; perilymphatic fistula
  - Several minutes to 1 hour: posterior TIA; perilymphatic fistula
  - Hours: Ménière disease, migraine, acoustic neuroma
  - Days: early acute vestibular neuritis, CVA, migraine, MS
  - Weeks: psychogenic (constant symptoms without improvement)
- Provoking factors that help distinguish different causes of vertigo (2)[C]
  - Changes in head position: acute labyrinthitis, BPPV, cerebellar tumor, MS, perilymphatic fistula
  - Spontaneous episodes/no clear provoking factors: vestibular neuritis, TIA/CVA, Ménière disease, migraine, MS
  - Recent URI: vestibular neuritis
  - Stress: psychogenic causes, migraine
  - Immunosuppression: herpes zoster oticus
  - Changes in ear pressure, trauma, loud noises: perilymphatic fistula
- Symptoms that help distinguish between common causes (does not include all, see differential diagnoses) (2,3)[C]
  - Aural fullness: acoustic neuroma, Ménière disease
  - Ear/mastoid pain: acoustic neuroma, acute middle ear disease (AOM, herpes zoster oticus)
  - Facial weakness: acoustic neuroma, herpes zoster oticus
  - Focal neurologic findings: cerebellar tumor, CVD, MS

- Headache: acoustic neuroma, migraine
- Hearing loss: Ménière disease, acoustic neuroma, otosclerosis, labyrinthitis, herpes zoster oticus, transient ischemic attack (TIA), cholesteatoma, perilymphatic fistula
- Imbalance: acute vestibular neuritis (moderate), cerebellar tumor (severe)
- Phonophobia/photophobia: migraine
- Rash: herpes zoster oticus
- Tinnitus: acute labyrinthitis, acoustic neuroma, Ménière disease

## PHYSICAL EXAM

- Neurologic: cranial nerves. Consider the HINTS battery to when evaluating for a central cause (4)[C].
  - Horizontal **Head Impulse**: Rapidly bring patient's head to midline from 20 degrees. Patients with peripheral vertigo will show rapid saccades to refocus on target. In central vertigo, eyes will stay on target.
  - Direction-changing **Nystagmus**: Nystagmus typically is unidirectional. Nystagmus that changes direction with eye motion indicates a central lesion.
  - Test of **Skew**: Vertical eye movement during cover-uncover test indicates a central lesion. A normal test has no movement.
  - A combination of these findings is 96.8% sensitive, 98.5% specific for CVA/other central cause (HINTS positive) (4)[C].
- Balance
  - Peripheral: mild to moderate, able to walk
  - Central: severe, unable to walk
- Dix-Hallpike maneuver (2)[C]: Rapidly move the patient from seated to supine position with the head turned 45 degrees to the right. Observe for nystagmus and ask the patient if he or she is experiencing vertigo. Note: There may be 5 to 20 seconds of latency before nystagmus/vertigo begin. Wait until symptoms resolve, then return the patient to the sitting position. Always repeat on the left side.
  - The presence of extinguishing horizontal nystagmus is a positive test, consistent with peripheral causes and specifically posterior canal BPPV.
  - If induced nystagmus does not subside, consider central causes.
  - Vertical nystagmus always indicates a central cause.

- In primary care, PPV of 83% for BPPV and NPV of 52%
- If Dix-Hallpike is negative, check for lateral canal BPPV: With patient supine, rapidly rotate head 90 degrees. If nystagmus induced, wait for it to subside, then return to neutral. Repeat on other side. Nystagmus with this test suggests lateral canal BPPV (5)[C].
- Head and neck: tympanic membranes
  - Vesicles: herpes zoster oticus
  - Cholesteatoma
  - Infection
- Cardiovascular: orthostatic changes in BP, dehydration/autonomic dysfunction

## *DIFFERENTIAL DIAGNOSIS*

- Acoustic neuroma
- Anxiety disorder
- Arrhythmia
- BPPV (posterior or lateral canal)
- Cerebellar degeneration, hemorrhage, or tumor
- Dehydration
- Eustachian tube dysfunction/middle ear effusion
- Hypoglycemia
- Labyrinthitis/labyrinthine concussion
- Ménière disease
- Multiple sclerosis
- Orthostatic hypotension
- Perilymphatic fistula
- Parkinson disease
- Peripheral neuropathy
- Syphilis
- Superior canal dehiscence syndrome
- Vascular ischemia

- Vertiginous migraine
- Vestibular neuritis/ototoxicity

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Labs not routinely necessary and identify a cause in <1% of patients (2)[C]
- Stat MRI if a central cause is suspected to rule out stroke. CT cannot reliably see the posterior fossa and will not show changes in the early stages of an infarct. Vertigo may be the only symptom of acute stroke (4)[C].
- ENT/audiology referral if MŽnière disease is suspected for electronystagmography (1,2,4)[C].
- If acoustic neuroma is suspected, either CT or MRI to evaluate internal auditory canal (1,2,4)[C].

### Diagnostic Procedures/Other

Audiometry if acoustic neuroma or MŽnière disease is suspected

## TREATMENT

### GENERAL MEASURES

Treatments depend on cause.

- BPPV: Epley maneuver (1,3,5)[A] and modified Epley maneuver (1)[B] (Epley maneuver-YouTube)
- Vestibular neuritis and labyrinthitis
  - Vestibular-suppressant medications (1)[C],(3)
  - Vestibular rehabilitation exercises (1)[B],(3)
  - No evidence to support improvement of symptoms with corticosteroid use (6)[B]
- MŽnière disease (see separate topic) (1)[B],(3):
  - Low-salt diet (<1 to 2 g/day)
  - Diuretics such as hydrochlorothiazide
- Vascular ischemia: prevention of future events through BP reduction, lipid lowering, smoking

cessation, antiplatelet therapy, and anticoagulation, if necessary. MRI or CT if suspected (1,4) [C],(3)

- Vertiginous migraines: dietary and lifestyle modifications, vestibular rehab, prophylactic and abortive medications (1)[B],(3)
- Psychological: SSRIs are better than benzodiazepines for anxiety related vertigo. Use slow titration to avoid worsening symptoms (1)[B].

## **MEDICATION**

Avoid use of medication in mild cases. Use for acute phase only (few days at most), as longer term use may impair adaptation/compensation by the brain (1). Medications not recommended for BPPV (1,3,5)[C]

- Meclizine: 12.5 to 50 mg POq4-8h (1)
  - Dimenhydrinate: 25 to 100 mg PO, IM, or IV q4-8h (1) Precautions: prostatic hyperplasia, glaucoma
  - Adverse effects: sedation, xerostomia
  - Interactions: CNS depressants
- Prochlorperazine: 5 to 10 mg PO or IM q6-8h; 25 mg rectally q12h; 5 to 10 mg by slow IV over 2 minutes (1)
  - Contraindications: blood dyscrasias, age <2 years, hypotension
  - Precautions: acutely ill children, glaucoma, breast cancer history, impaired cardiac function, prostatic hyperplasia
  - Adverse effects: sedation, extrapyramidal effects
  - Interactions: phenothiazines, tricyclic antidepressants
- Metoclopramide: 5 to 10 mg PO q6h, 5 to 10 mg slow IV q6h (1)
  - Contraindications: concomitant use of drugs with extrapyramidal effects, seizure disorders
  - Precautions: history of depression, Parkinson disease, hypertension
  - Adverse effects: sedation, fluid retention, constipation
  - Interactions: linezolid, cyclosporine, digoxin, levodopa
- Psychiatric causes (1)
  - SSRIs for depression/anxiety (1)[B]
  - Lorazepam (Ativan) 0.5 to 2 mg orally, IM, or IV q4-8h for short-term relief of more severe

anxiety

- Diazepam (Valium) 2 to 10 mg orally or IV q4-8h for short-term relief of more severe anxiety

## *Geriatric Considerations*

Use vestibular-suppressant medications with caution due to increased risk of falls and urinary retention.

## *Pregnancy Considerations*

Meclizine and dimenhydrinate are pregnancy Category B.

## **ISSUES FOR REFERRAL**

Consider referral to otolaryngologist, ENT specialist, vestibular rehabilitation therapist, or neurologist if patient requires further care.

## **ADDITIONAL THERAPIES**

- Epley maneuver/modified Epley maneuver for BPPV to displace calcium deposits in the semicircular canals (1,3,5)[A]
  - Effective for short-term symptomatic improvement and for converting patient from positive to negative Dix-Hallpike maneuver (1)[A] and some studies suggest long-term relief (1)[C]
  - Contraindications: carotid stenosis, unstable cardiac disease, severe neck disease
- Lateral canal BPPV may respond to barbecue roll maneuvers (5)[C].
- Vestibular rehabilitation exercises: ball toss, lying-to-standing, target-change, thumb-tracking, tightrope, walking turns (1)[B]

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Balance exercises should be adhered to for symptom reduction and return to normal activities of daily living (ADLs).

### ***Patient Monitoring***

After 1 to 2 weeks, assess for the following:

- Recurrence of symptoms

- New-onset symptoms
- Medication-related adverse effects
- Relief from vestibular rehabilitation exercises

## **DIET**

- Restricted salt intake for MŽnière disease
- Dietary modifications for vertiginous migraine

## **PATIENT EDUCATION**

- Reduce sodium intake (MŽnière disease).
- Avoid triggers such as caffeine/alcohol (vertiginous migraine).

## **PROGNOSIS**

Depends on diagnosis and response to treatment

## **COMPLICATIONS**

- Anxiety
- Depression
- Disability
- Injuries from falls

## Clinical Pearls

&NA;

- Risk factors include migraines, CVD/CVD risk factors, ototoxin exposure/meds, trauma/barotrauma, perilymphatic fistula, heavy weight bearing, psychosocial stress.
- Acute vertigo with a normal horizontal head impulse, direction-changing nystagmus, and skew

deviation (HINTS positive) is highly sensitive and specific for CVA.

- Nystagmus indicates a positive Dix-Hallpike test implies a peripheral cause. If nystagmus persists, investigate a central cause.
- The Epley maneuver is recommended for the treatment of BPPV; the modified Epley can be performed at home.
- Medications are not recommended for BPPV.

# Vertigo, Benign Paroxysmal Positional (BPPV)

Chirag N. Shah, MD

Kyung In Yoon, MD

## BASICS

### DESCRIPTION

- Benign paroxysmal positional vertigo (BPPV) is a mechanical disorder of the inner ear characterized by a brief period of vertigo experienced when the position of the patient's head is changed relative to gravity.
- The brief period of vertigo is caused by abnormal stimulation of <sup>31</sup> of the 3 semicircular canals of the inner ear, with the posterior canal most commonly affected.
- BPPV is the single most common cause of vertigo.

### EPIDEMIOLOGY

- The lifetime prevalence of BPPV is 2.4%, and the 1-year incidence is 0.6%. The age of onset is most commonly between the 5th and 7th decades of life, and the incidence of BPPV increases with each decade of life, peaking in the 6th and 7th decades.
- Prevalent sex: female > male
- BPPV affects the quality of life of elderly patients and is associated with reduced activities of daily living scores, falls, and depression.

### Prevalence

- Common
- 2.4% with one year incidence 0.6%

### ETIOLOGY AND PATHOPHYSIOLOGY

- In BPPV, calcite particles (otoconia) that normally weight the sensory membrane of the maculae become dislodged and settle into the semicircular canal, changing the dynamics of the canal. Reorientation of the canal relative to gravity causes the otoconia to move to the lowest part of the canal, causing displacement of the endolymph, deflection of the cupula, and activation of the primary afferent. This results in the generation of nystagmus and the

associated sensation of vertigo.

- BPPV may be idiopathic, posttraumatic, or associated with viral neurolabyrinthitis.

## DIAGNOSIS

- The diagnosis is established based on history and findings on positional testing, clarified by Dix and Hallpike in 1952 (1,2)[A].
- Positional tests place the plane of the canal being tested into the plane parallel with gravity.

## HISTORY

- Brief episodes of vertigo (sensation that the room is spinning) associated with
  - Rolling over in bed
  - Getting out of bed
  - Looking up (referred to as “top-shelf syndrome”)
  - Bending forward
  - Quick head movements
- Patients may also complain of light-headedness or feeling “off balance.”
- Frequently, patients complain of nausea and, if severe enough, vomiting.

## PHYSICAL EXAM

- The Dix-Hallpike Test (DHT) is used to diagnose BPPV (1)[A]. The test provokes the characteristic nystagmus associated with the symptoms of vertigo. For the DHT, the estimated sensitivity is 79% (95% CI 65-94) and specificity is 75% (95% CI 33-100) (3)[B].
- To perform the DHT, the patient is positioned in long-sitting on the exam table with the knees extended. The head is then rotated 45 degrees toward the side to be tested. The patient is then lowered quickly to supine with the head 30 to 40 degrees below the horizontal, over the edge of the exam table. The position is maintained for a minimum of 45 to 60 seconds.
- For each position, the clinician notes the direction of the fast phase of the nystagmus and the latency and duration of the nystagmus.

Posterior canal BPPV:

- In the head-hanging position, the otoconia move away from the ampullary organ resulting in upward ipsi-torsional nystagmus.
- The superior poles of the eyes beat up toward the forehead and rotate toward the lower-most ear, the involved ear

- On return to the seated position, the otoconia move toward the ampullary organ resulting in the nystagmus reversing direction.
- The latency of onset of nystagmus is 1 to 45 seconds, and the duration is usually <1 minute.
- The nystagmus fatigues (reduction in the severity of symptoms) with repeated positioning.

#### Horizontal canal BPPV

- Directional-changing positional nystagmus is observed in the test positions; the eyes will beat linearhorizontal toward the ground (geotropic nystagmus) or beat toward the sky (apogeotropic nystagmus).
- One position may illicit a stronger nystagmus response. The side with great intensity indicates the side involved with geotropic lateral canal BPPV and the uninvolved side with apogeotropic lateral canal BPPV.

#### Anterior canal BPPV

- In the head-hanging position, the nystagmus is downbeating and torsional, with the top of the eye torting away from the lower ear.
- Usually caused by Òcanal switchingÓ from canalith repositioning procedure (CRP) maneuvers
- No further testing is indicated unless the diagnosis is uncertain, or there are additional symptoms and signs unrelated to BPPV that warrant testing.

## ***DIFFERENTIAL DIAGNOSIS***

- Orthostatic hypotension and other disorders that cause low BP; symptoms usually occur when the patient stands up.
- Damage to the brainstem or cerebellum can cause positional vertigo but is accompanied by other neurologic signs and usually has a different pattern of nystagmus.
- Low spinal fluid pressure may cause positional symptoms that are better when the patient lies down.
- Migraine-associated vertigo
- Traumatic brain injury

## **TREATMENT**

- The CRP or Epley maneuver is effective in the treatment of posterior canal BPPV (1)[A]. Using a particle repositioning maneuver, the clinician moves the patient through a series of positions. With each position, the otoconia settles to the lowest part of the canal. The debris is moved

around the arc of the canal into the vestibule. In randomized controlled trials, the average short-term success rate of the CRP following one treatment session is  $80 \pm 9\%$  (1)[A].

- The clinician moves the patient through a series of four provoking positions:
  - 1) Placement of the right posterior canal (involved canal) in the right head-hanging position of the DHT
  - 2) The head is then rotated a total of 90 degrees toward the left (uninvolved side) into 45 degrees of left head rotation.
  - 3) Maintaining 45 degrees of left head rotation, the patient is rolled onto the left side (uninvolved side) with the head slightly elevated from the supporting surface.
  - 4) The patient then sits up and flexes the neck 36 degrees. Each position is maintained for a minimum of 45 seconds or as long as the nystagmus lasts. The procedure is repeated three times.

---

P.1117

- CRP is the best maneuver for posterior BPPV and should be offered to all age groups (4)[A].
- Semont maneuver is also another maneuver, less superior when performed alone (4)[A].
- Contraindications are carotid stenosis, unstable cardiac disease, and severe neck disease. If the CRP is ineffective, self-administered CRP is performed at home (1)[A]. The patient performs the CRP on the bed with the head extended over the edge of a pillow. Better outcomes are achieved with a combination of CRP with self-administered CRP (1)[A].
- CRP and Semont are ineffective for horizontal BPPV; variations of the Lempert maneuver, barbecue roll, or Gufoni maneuver are widely used treatment methods for horizontal BPPV.
- Postmaneuver activity restrictions were previously advocated but in controlled trials it did not differ in clinical outcomes, which suggests that restrictions do not appear to affect the efficacy of positional maneuvers (2,4)[A].

## **MEDICATION**

- Vestibular suppressant medications are not recommended for treatment of BPPV, other than for the short-term management of vegetative symptoms (3)[A].
- Antiemetics such as ondansetron (Zofran) may be considered for prophylaxis for patients who have had severe nausea or vomiting with the DHT.
- Vestibular suppressants such as benzodiazepines and antihistamine anticholinergics such as meclizine should be avoided because they may suppress nystagmus during the DHT and treatment.

## ISSUES FOR REFERRAL

Consider a referral to a specialist if BPPV is unresponsive to treatment or if the patient is diagnosed with atypical BPPV involving the anterior or lateral canal. Other maneuvers are available for treatment of typical and atypical BPPV. Consider referring to a physical therapist, otolaryngologist, or neurologist.

## ADDITIONAL THERAPIES

- Brandt-Daroff exercises and habituation exercises are not as effective as self-administered CRP. At 1 week, the average success rate for the Brandt-Daroff exercise is 23-24% compared with 90% for self-administered CRP (1,5)[A].
- Surgical intervention is rarely indicated, except for refractory BPPV, and includes posterior canal occlusion and singular neurectomy.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

The patient should follow up within a week after treatment to ensure resolution.

### PATIENT EDUCATION

A number of illustrative videos are available at [www.youtube.com](http://www.youtube.com) for education and self-CRP maneuvers.

### PROGNOSIS

80% cure rate with CRP maneuvers, with a 30% recurrence rate at 1 year (6)[A], and 44% redevelop BPPV within 2 years (1)[A]

### COMPLICATIONS

During the maneuvers, a canal conversion may occur. The debris from the canal being treated may reflux into another canal.

## Codes

&NA;

## ICD10

- H81.10 Benign paroxysmal vertigo, unspecified ear
- H81.12 Benign paroxysmal vertigo, left ear
- H81.11 Benign paroxysmal vertigo, right ear

## Clinical Pearls

### **&NA;**

- The diagnosis of BPPV is based on history and findings on positional testing (DHT).
- The typical presentation is reports of transient episodes of vertigo (sensation that the room is spinning) associated with a change in position of the head relative to gravity.
- BPPV may be treated effectively with particle repositioning maneuvers in the office and at home.
- Vestibular suppressant medications and antiemetics are not recommended for treatment of BPPV, other than for the short-term management of symptoms.

# Vincent Stomatitis

Steven A. House, MD, FAAFP, FAAHPM, HMDC

## BASICS

### DESCRIPTION

- Inflammatory oral infection of the gingiva, characterized by gingival necrosis, bleeding, and pain
- Disease caused by *Fusobacterium*, *Prevotella intermedia*, spirochetes, and heavy growth of oral flora
- Concomitant infection with Epstein-Barr virus, herpes simplex virus, and type 1 human cytomegalovirus is common.
- Organisms invade gingiva and oral papillae with the formation of a pseudomembranous exudate.
- Clinical presentation includes ulceration, halitosis, pain, bleeding, and necrosis. It is differentiated from other periodontal diseases in that onset is rapid, papillae are ulcerated and appear punched out, and there is interdental necrosis (1).
- Synonym(s): Vincent angina; trench mouth; acute necrotizing ulcerative gingivitis

### EPIDEMIOLOGY

#### *Incidence*

- Predominant age: 18 to 30 years in developed countries
- 3 to 14 years of age among malnourished children

#### *Prevalence*

- A Chilean study of 9,203 students aged 12 to 21 years revealed a prevalence of 6.7%.
- Overall prevalence decreases with age.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Impaired host immunologic response due to immunocompromise or malnutrition

- Loss of integrity of the oral mucosa
- Increased bacterial attachment with herpesvirus active infection

## *RISK FACTORS*

- Poor oral hygiene
- Orthodontics (2)
- Infrequent or absent dental care
- Malnutrition
- Tobacco use
- Herpesvirus infection
- Immunosuppression
- Psychological stress
- Diabetes, especially if uncontrolled (3)
- Down syndrome
- Pregnancy (3)

## *GENERAL PREVENTION*

- Regular dental care
- Proper oral hygiene
- Appropriate nutrition
- Prompt recognition and institution of therapy
- Stress management

## *COMMONLY ASSOCIATED CONDITIONS*

- Bacteremia
- Osteomyelitis
- Tooth loss
- Noma/cancrum oris, which can be life-threatening.
- Aspiration pneumonia

# DIAGNOSIS

## HISTORY

- Acute onset of gingival ulcer
- Halitosis
- Painful, bleeding, and inflamed gingiva
- Fever
- Malaise
- History of immunosuppression chemotherapy, HIV infection
- History of herpesvirus infection

## PHYSICAL EXAM

- Ulceration of the oral papillae
- Inflamed, erythematous gingiva
- Formation of gray, pseudomembranous exudate
- Necrotic tissue on gingiva and surrounding structures
- Cervical lymphadenopathy

## DIFFERENTIAL DIAGNOSIS

- Herpes simplex virus
- Periodontitis
- Pericoronitis
- Medication side effects
- Oral malignancy
- Xerostomia
- Diphtheria
- Lymphoma/leukemia
- Primary syphilis
- Ascorbic acid deficiency
- Gingivitis
- Behçet disease

# DIAGNOSTIC TESTS & INTERPRETATION

## Initial Tests (lab, imaging)

- Diagnosis is primarily based on clinical exam, but if systemic illness or localized spread to surrounding tissues is suspected, the following studies should be considered:
  - Aerobic and anaerobic cultures of inflamed or debrided tissue
  - Group A strep rapid antigen detection assay
  - Group A strep throat culture
  - Blood cultures if systemic involvement
  - Dental radiographs
  - Facial radiographs or CT of the neck and sinuses if infection has progressed

P.1119

## TREATMENT

### MEDICATION

- Decision regarding locus of treatment (outpatient or inpatient) and route (PO or IV) depends on the degree of systemic illness present and on the involvement of structures in the neck.
- Medication regimens provided below are for outpatient treatment.

#### First Line

- Penicillin V K 500 mg q6h for 7 to 10 days (4)[C] *or*
- Amoxicillin 500 mg TID for 7 days *or*
- Amoxicillin-clavulanate 875 mg q12h for 7 to 10 days if more concerned regarding complications

#### Second Line

- Metronidazole 500 mg q8h for 7 to 10 days *or*
- Erythromycin 500 mg BID for 7 days (if PCN allergy) (4)[C] *or*
- Clindamycin 450 mg q8h for 7 to 10 days (if PCN allergy) (1)[C]

## *ISSUES FOR REFERRAL*

Patients can be evaluated and treated by oral surgeon, dentist/periodontist, or ear, nose, and throat specialist depending on patient preference and severity of infection.

## *ADDITIONAL THERAPIES*

- Chlorhexidine gluconate 0.12% BID or salt water rinses (2)[C]
- Pain management with NSAIDs (5)[C]

## *SURGERY/OTHER PROCEDURES*

- Debridement of inflamed and necrotic tissue
- Dental extraction

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Failure of oral antibiotics and disease progression
- Need for parenteral antibiotics and analgesia
- Inability to meet nutritional and/or hydration needs

### *IV Fluids*

May be required if patient is unable to tolerate oral fluids

### *Discharge Criteria*

- Arrest of disease progression and improvement at site
- Ability to tolerate oral antibiotics and fluids
- Oral analgesia is effective.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Frequent dental cleanings and examinations

### *DIET*

Proper nutrition

- Multivitamin supplementation

## **PATIENT EDUCATION**

- Proper nutrition
- Appropriate oral hygiene
- Tobacco cessation
- Stress management

## **COMPLICATIONS**

- Malnutrition
- Pain
- Poor dentition, tooth loss
- Systemic infection
- Involvement of soft tissues and structures of the neck

## Codes

&NA;

### ICD10

A69.1 Other Vincent's infections

## Clinical Pearls

&NA;

- Poor oral hygiene and immunosuppression are key factors in infection.
- Early recognition and institution of therapy decrease complications.
- Penicillin is the drug of choice for patients not systemically ill.

# Vitamin B<sub>12</sub> Deficiency

Justin D. Chaltry, DO

Katie L. Westerfield, DO

## BASICS

- Vitamin deficiency related to inadequate intake or absorption of cobalamin (vitamin B<sub>12</sub>)
- Cobalamin is critical for CNS myelination and normal functioning.
- Deficiency can cause a multitude of symptoms and disorders including megaloblastic anemia, bone marrow dysfunction, and diverse and potentially irreversible neuropsychiatric changes.
- Neuropsychiatric disorders are due to demyelination of cervical, thoracic dorsal, and lateral spinal cords; demyelination of white matter; and demyelination of cranial and peripheral nerves (1)[C].
- Low vitamin B<sub>12</sub> level can lead to elevated methylmalonic acid (MMA) and homocysteine levels.
- Elevated MMA causes abnormality in fatty acid synthesis affecting neuronal membrane.
- Elevated homocysteine is neurotoxic through overstimulation of the *N*-methyl-D-aspartate (NMDA) receptor and toxic to vasculature through activation of coagulation system and effects on endothelium.

## DESCRIPTION

Normal B<sub>12</sub> absorption

- B<sub>12</sub> present in animal-source foods (meat, fish, eggs, milk) and foods fortified with B<sub>12</sub>
- Dietary vitamin B<sub>12</sub> (cobalamin) bound to food is cleaved by acids in stomach and bound to haptocorrin (commonly known as R-factor).
- Duodenal proteases cleave B<sub>12</sub> from haptocorrin.
- In duodenum, B<sub>12</sub> uptake depends on binding to intrinsic factor (IF) secreted by gastric parietal cells.
- B<sub>12</sub> -IF complex is absorbed by terminal ileum into portal circulation.
- Body's B<sub>12</sub> stored in liver = 50-90%

- B<sub>12</sub> secreted into bile from liver recycled via enterohepatic circulation
- Delay 5 to 10 years from onset of B<sub>12</sub> deficiency to clinical symptoms due to hepatic stores and enterohepatic circulation
- Typical Western diet: 5 to 30  $\mu\text{g}/\text{day}$ ; however, only 1 to 5  $\mu\text{g}/\text{day}$  is effectively absorbed.
  - Recommend 2.4  $\mu\text{g}/\text{day}$  for adults and 2.6  $\mu\text{g}/\text{day}$  during pregnancy and 2.8  $\mu\text{g}/\text{day}$  during lactation (most prenatal vitamins contain B<sub>12</sub>)

## EPIDEMIOLOGY

### Prevalence

- Endemic area: Northern Europe, including Scandinavia; more common in those of African ancestry
- Increasing recognition in breastfed-only infant populations with vitamin B<sub>12</sub> deficient mothers
- Prevalence 5-20% in developed countries
  - 12% in elderly living in community
  - 30-40% in elderly in institutions, sick, or malnourished
  - 5% patients in tertiary reference hospitals
- Prevalence by age group
  - 20 to 39 years old: prevalence 3%
  - 40 to 59 years old: prevalence 4%
  - >70 years old: prevalence 6%

## ETIOLOGY AND PATHOPHYSIOLOGY

- Decreased oral intake
  - Vegetarians and vegans: B<sub>12</sub> is found in animal source foods; however, strict vegetarians uncommonly develop deficiency because only 1 mg/day is needed, with adequate amounts present in legumes.
- Decreased IF
  - Pernicious anemia (PA): can be associated with autoantibodies directed against gastric

parietal cells and/or IF

- Chronic atrophic gastritis: autoimmune attack on gastric parietal cells causing autoimmune gastritis and leading to decreased IF production
- Gastrectomy: Removal of entire or part of stomach decreases amount of parietal cells.
- Decreased ileal absorption
  - Crohn disease: Terminal ileal inflammation decreases body's ability to absorb B<sub>12</sub>.
  - Chronic alcoholism: decreases body's ability to absorb B<sub>12</sub>
  - Ileal resection
  - Pancreatic insufficiency: Pancreatic proteases are required to cleave the vitamin B<sub>12</sub>-haptocorrin bond to allow vitamin B<sub>12</sub> to bind to intrinsic factor.
  - *Helicobacter pylori* infection impairs release of B<sub>12</sub> from bound proteins.
- Medications: Proton pump inhibitors (PPIs), H<sub>2</sub> antagonists, and antacids decrease gastric acidity, inhibiting B<sub>12</sub> release from dietary protein; metformin
- Hereditary (rare)
  - Imerslund-Grasbeck disease (juvenile megaloblastic anemia)
  - Congenital deficiency of transcobalamin
  - Severe methylene tetrahydrofolate reductase deficiency
  - Abnormalities of methionine synthesis

Causes:

- Food-cobalamin malabsorption syndrome
  - As many as 60-70% of cases
  - Primary cause in elderly
  - Pathophysiology: inability to release cobalamin from food or binding protein, especially if in the setting of hypochlorhydria
  - Seen in atrophic gastritis, long-term ingestion of antacids and biguanides, possible relationship to *H. pylori* infection
- PA
  - 15-30% of all cases; most frequent cause of severe disease. Neurologic disorders are

common presenting complaints.

- Common in elderly, as high as 20%, with mild atrophic gastritis, hypochlorhydria, and impaired release of dietary vitamin B<sub>12</sub>
- Autoimmune disease with destruction of gastric fundal mucosa cells via a cell-mediated process
- Anti-gastric parietal cell antibodies: sensitivity >90%, specificity 50%; use for screening test
- Anti-intrinsic factor antibodies: sensitivity 50%
- Associated with other autoimmune diseases
- Insufficient dietary intake: 2% of cases; vegans or long-standing vegetarians
- Infants born to vitamin B<sub>12</sub>-deficient mothers may have deficiency or develop it if breastfed exclusively.
- Intestinal causes:
  - 1% of cases; prevalence depends on risk factors, such as surgical conditions
  - Gastrectomy: due to decreased production of intrinsic factor
  - Gastric bypass: appears 1 to 9 years after surgery, prevalence 12-33%
  - Ileal resection or disease
  - Fish tapeworm
  - Severe pancreatic insufficiency
- Undetermined etiology
  - 1/10 of cases

## *Genetics*

Imerslund-Grasbeck disease (juvenile megaloblastic anemia) caused by mutations in the amnionless (AMN) or cubilin (CUBN) genes with autosomal recessive pattern of inheritance; inadequate ileal uptake of B<sub>12</sub>-IF complex and B<sub>12</sub> renal protein reabsorption

## **GENERAL PREVENTION**

Risk factors: vegan diet, age >65 years, female, chronic atrophic gastritis, Crohn disease or other ileal disorders, chronic medication use including PPI, metformin, H<sub>2</sub> antagonists

## DIAGNOSIS

Symptoms and physical exam findings:

- Asymptomatic patients may be diagnosed by the incidental finding of anemia or an elevated mean corpuscular volume (MCV) during routine testing or evaluation of unassociated disorders.
- Hematologic
  - Frequent: macrocytosis, neutrophil hypersegmentation, spinal cord medullar megaloblastosis (blue spinal cord)
  - Rare: isolated thrombocytopenia and neutropenia, pancytopenia
  - Very rare: hemolytic anemia, thrombotic microangiopathy with schistocytes
- Neuropsychiatric
  - Frequent: sensory polyneuritis, paresthesias, positive Babinski sign, weakness, gait unsteadiness, loss of proprioception (impaired vibratory sensation, positive Romberg, ataxia, hyperreflexia)
  - Classic, but uncommon: subacute combined degeneration of spinal cord associated with PA; myelin degeneration in the lateral and posterior columns; ataxia, proprioception and vibration loss, bowel and bladder incontinence, orthostatic hypotension, decreased memory, mania, delirium, psychosis, depression
- Digestive
  - Classic: Hunter glossitis, jaundice, and high lactate dehydrogenase and bilirubin
  - Possible: abdominal pain, dyspepsia, nausea, vomiting, diarrhea
  - Rare: mucocutaneous ulcers
- Other
  - Frequent: pallor, edema, jaundice
  - Under investigation: chronic vaginal and urinary infections, atrophy of vaginal mucosa, hypofertility, venous thromboembolism, angina, miscarriages
  - Commonly insidious and nonspecific; thus, delay in diagnosis is common.

P.1121

## HISTORY

- Underlying disease associated with vitamin B<sub>12</sub> deficiency

Fatigue, anorexia

- Depression
- Falls (due to diminished proprioception)
- Loss of sensation in “stocking-glove” distribution
- Glossitis/loss of sense of taste, and other subtle, nonspecific neurologic symptoms

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Measurement of vitamin B<sub>12</sub>, CBC (MCV)
- Measurement of B<sub>12</sub> may be low or low normal depending on institution's cutoff value.
  - 65-95% sensitivity levels <200 pg/mL
  - May need additional tests such as MMA and homocysteine if vitamin B<sub>12</sub> level is low normal (<350 pg/mL) and no evidence of anemia depending on clinical suspicion
- If high suspicion on normal B<sub>12</sub> with high/normal MCV, consider testing MMA and homocysteine levels.
- MCV often increased
- Measurement of MMA
  - More sensitive and specific than homocysteine
  - Levels increased in renal failure and volume depletion
- Measurement of homocysteine
  - Levels increased in folate deficiency, renal failure, and homocystinuria
- MMA and homocysteine levels only reliable in an untreated patient, as levels fall with supplementation
- Other tests: folate and other markers of anemia (iron studies)
- MCV may be normal, decreased, or increased if vitamin B<sub>12</sub> deficiency coexists with other forms of anemia, such as iron deficiency or hemolysis. Thus, RBCs may be normochromic, normocytic, or hypochromic microcytic.

### **ALERT**

- Low levels of vitamin B<sub>12</sub> are seen in folate deficiency, HIV, and multiple myeloma.

- Elevated levels of vitamin B<sub>12</sub> are seen in renal disease, occult malignancy, and alcoholic liver disease and as a result of technical error.
- Macrocytosis may be due to folate deficiency, reticulocytosis, medications, bone marrow dysplasia, and hypothyroidism or be masked by concomitant microcytic anemia.
- Serum homocysteine and MMA
  - Elevated in B<sub>12</sub> deficiency secondary to decreased metabolism
  - If both are normal, B<sub>12</sub> deficiency is effectively ruled out.
  - If MMA is normal and homocysteine is increased, think folate deficiency.
- PA
  - Check antibody to intrinsic factor; positive test is confirmatory for PA, but sensitivity is only 50-70%.
  - Anti-parietal cell antibody positivity indicates PA.
  - For patients who are antibody positive, consider screening for autoimmune thyroid disease.

## *Pregnancy Considerations*

- Because B<sub>12</sub> crosses the placenta, pregnant women with low levels of B<sub>12</sub> are at higher risk of having children with neural tube defects, congenital heart defects, developmental delay, and failure to thrive.
- Exclusively breastfed infants of mothers who are B<sub>12</sub> deficient are at risk of developing B<sub>12</sub> deficiency. Infants breastfed from B<sub>12</sub>-deficient mothers might not show signs or symptoms until 4 to 6 months of age, which may include developmental regression, feeding difficulties, lethargy, or hypotonia.

## *Diagnostic Procedures/Other*

- Bone marrow exam is usually unnecessary in the evaluation of B<sub>12</sub> deficiency because of the inability to differentiate from folate deficiency.
- Spinal cord imaging is not standard; MRI in selected cases, especially with severe myelopathy

## **TREATMENT**

## *MEDICATION*

- Parenteral cyanocobalamin replacement recommended in patients with severe neurologic symptoms: IM cyanocobalamin (2)[C]
  - 1,000  $\mu$ g/day for 7 days, then
  - 1,000  $\mu$ g weekly for 4 weeks, then
  - 1,000  $\mu$ g monthly for life
- High-dose, daily oral cyanocobalamin at doses of 1,000 to 2,000  $\mu$ g are as effective as monthly intramuscular injection and is the preferred route of initial therapy in most circumstances because it is cost-effective and convenient (3)[A]. Requires greater patient compliance. Transnasal and buccal preparations of cyanocobalamin are also available; however, further study is needed.

### **ALERT**

Folic acid without vitamin B<sub>12</sub> in patients with PA is contraindicated; it will not correct neurologic abnormalities.

## **INPATIENT CONSIDERATIONS**

### **Admission Criteria/Initial Stabilization**

- Consider blood transfusion for severe anemia.
- Draw blood for hematologic parameters before transfusing.

## **ONGOING CARE**

### **FOLLOW-UP RECOMMENDATIONS**

#### **Patient Monitoring**

- Hematologic
  - Reticulocytosis in 1 week
  - Rise in hemoglobin beginning at 10 days; usually will return to normal in 6 to 8 weeks
  - Monitor potassium in profoundly anemic patients (hypokalemia due to potassium use).
  - Serum MMA decreases with replacement therapy.
- Neurologic: can note improvement within 3 months of treatment; however, maximum improvement noticed at 6 to 12 months. Some symptoms may be irreversible.

## DIET

Meat, animal protein, and legumes unless contraindicated

## REFERENCES

## Codes

### &NA;

## ICD10

- E53.8 Deficiency of other specified B group vitamins
- D51.0 Vitamin B12 defici anemia due to intrinsic factor deficiency

- D51.3 Other dietary vitamin B12 deficiency anemia

## Clinical Pearls

### &NA;

- Consider screening for B<sub>12</sub> deficiency in high-risk patients including the elderly and monitoring B<sub>12</sub> levels annually if on metformin or **on chronic PPIs**.
- Correcting folate deficiency without treating with cyanocobalamin in megaloblastic anemia may correct hematologic but not neurologic disorders.
- Vitamin B<sub>12</sub> deficiency can coexist with other causes of anemia, including iron deficiency or hemolysis; thus, MCV can be normal, decreased, or increased.
- For patients with PA, cyanocobalamin replacement must be lifelong.
- Patients with PA are at increased risk for other autoimmune conditions as well as gastric malignancy.

# Vitamin D Deficiency

Marissa Hamrick, MD

Frank J. Domino, MD

Samir Malkani, MD, MRCP(UK)

## BASICS

This topic covers the commonly acquired vitamin D deficiency and not type II vitamin D-resistant rickets/type I pseudovitamin D-resistant rickets (both rare autosomal recessive disorders).

## DESCRIPTION

- Vitamin D is both a hormone and a vitamin.
- Cholecalciferol (D<sub>3</sub>) is synthesized in the skin by exposure to ultraviolet B (UV-B) radiation.  
Ergocalciferol (D<sub>2</sub>) and D<sub>3</sub> are present in foods.
- D<sub>2</sub> and D<sub>3</sub> are hydroxylated in the liver to 25 vitamin D (calcidiol), its major circulating form.
- Calcidiol is further hydroxylated in the kidney to the active metabolite 1,25 vitamin D (calcitriol).
- Hypocalcemia stimulates parathyroid hormone (PTH) to be secreted, which prompts the increased conversion of 25 vitamin D to 1,25 vitamin D.
  - 1,25 vitamin D decreases renal calcium and phosphorus excretion, increases intestinal calcium and phosphorus absorption, and increases osteoclast activity. These effects increase serum calcium.

## EPIDEMIOLOGY

- Unclear in general population
- In the community, a cohort study of asymptomatic adolescents in Boston found 24.1% were deficient, with 4.6% severely deficient.
- A study of hospitalized patients in Massachusetts found 57% vitamin D-deficient (VDD).
- Women with history of osteoporosis/osteoporotic fracture have high prevalence of vitamin D deficiency.

A cohort study in Arizona found >25% of adults were VDD; highest rates among African Americans and Hispanics

- A study of about 56,000 individuals across Europe found 13% to have vitamin D deficiency.

### *Pediatric Considerations*

NHANES data found 70% of children did not have sufficient 25-OH vitamin D serum levels (9% deficient and 61% insufficient), which was associated with an increase in BP and decrease in high-density lipoprotein (HDL) cholesterol.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Insufficient dietary intake of vitamin D and/or lack of UV-B exposure (in sunlight) results in low levels of vitamin D.
  - This limits calcium absorption, causing excess PTH to be released.
- PTH stimulates osteoclast activity, which helps to normalize calcium and phosphorous, but results in osteomalacia.
- Dietary deficiency
  - Inadequate vitamin D intake
- Inadequate sunlight exposure
  - Institutionalized/hospitalized patients
- Chronic illness: liver/kidney disease
- Malabsorptive states

### *Genetics*

Vitamin D-dependant rickets type 1 occurs due to inactivating mutation of the 1 alpha hydroxylase gene; as a result, calcidiol is autosomal recessive not hydroxylated to calcitriol.

## **RISK FACTORS**

- Inadequate sun exposure
- Female
- Dark skin
- Immigrant populations
- Low socioeconomic status

- Latitudes higher than 38 degrees
- Elderly
- Institutionalized
- Depression
- Medications (phenobarbital, phenytoin)
- Gastric bypass surgery
- Obesity

## **GENERAL PREVENTION**

- Adequate exposure to sunlight and dietary sources of vitamin D (plants, fish); many foods are fortified with vitamin D<sub>2</sub> and D<sub>3</sub>.
- Recommended minimum daily requirement from the 2010 Institute of Medicine Report is minimally 600 IU/day for those 1 to 70 years of age and 800 IU/day for those >70 years of age. Up to 4,000 IU/day is safe in healthy adults without risk of toxicity.
- Higher intake of vitamin D recommended for age >50 years
- 2005 and 2009: Meta-analysis demonstrated for ages 51 to 70 years, minimally recommended supplementation is 800 IU/day to prevent nonvertebral fractures.

### *Pediatric Considerations*

The American Academy of Pediatrics recommends all breast-fed babies receive 400 IU/day of vitamin D beginning within the first few days of life.

### *Pregnancy Considerations*

ACOG recommends data insufficient to screen all pregnancies; only those at risk and states it is safe to take 1,000 to 2,000 IU/day during pregnancy (1)[B].

### *Geriatric Considerations*

U.S. Preventive Services Task Force recommends seniors take at least 800 IU/day vitamin D to reduce risk of falls in community-dwelling older adults (2)[A].

## **COMMONLY ASSOCIATED CONDITIONS**

- Osteomalacia, osteoporosis
- Premenstrual syndrome
- Rickets

- Celiac disease
- Gastric bypass
- Chronic renal disease
- Bacterial vaginosis in pregnant women
- Hypertension

## **ALERT**

VDD is associated with risk of myocardial infarction (MI) and all-cause mortality (3)[A].

## **DIAGNOSIS**

- Nonspecific musculoskeletal complaints
- Weak antigravity muscles
- Fracture with minimal trauma

## **HISTORY**

- Senior citizens at risk of falling
- Renal disease
- GI (malabsorption) disorders
- Liver dysfunction
- Immigration from tropical to colder climates
- Dark-skinned/veiled individuals
- Housebound patients
- Women at perimenopause

## **PHYSICAL EXAM**

- Vague neurologic signs: numbness, proximal myopathy, paresthesias, muscle cramps, laryngospasm
- Chvostek sign: contraction of the facial muscles by tapping along the facial nerve
- Trousseau phenomenon: carpal spasms and paraesthesia produced by pressure on nerves and vessels of the upper arm, by inflation of a BP cuff
- Tetany, seizures

# DIAGNOSTIC TESTS & INTERPRETATION

## Initial Tests (lab, imaging)

- 25-OH vitamin D (most sensitive measure of vitamin D status)
- Vitamin D deficiency
  - <20 ng/mL
- PTH elevation: not routinely obtained unless severe deficiency
- Low-normal/low calcium and phosphorous
- Elevated alkaline phosphatase (in later disease)
- Plain radiographs: If atypical fracture, radiographs may show osteomalacia (pseudofractures/looser zones) in pelvis, femur, and fibula.
- Osteoporosis screen
  - Women <sup>3</sup>65 years with no risk factors
  - Women <sup>3</sup>60 years at risk: body weight <70 kg (best predictor)
  - Less evidence: smoking, low body mass index, family history, decreased activity, alcohol or caffeine use
  - African American women have higher bone density than Caucasians.

P.1123

## TREATMENT

- Treatment goals remain unclear, but current normal 25-OH vitamin D levels are based on suppression of PTH.
- Obesity: Treatment of VDD in obesity, especially those who are obese and depressed, improves depressive symptoms and may improve weight loss (4)[B].

### ALERT

All-cause mortality: Cochrane Systematic Review found vitamin D supplementation lowers all-cause mortality (5)[A].

## Geriatric Considerations

In senior citizens, serum 25-OH vitamin D of 20 ng/mL resulted in improved physical performance scores; recent data suggests supplementation may not improve fracture risk and remains unclear

about a true benefit.

## **MEDICATION**

- Vitamin D sufficient (25-OH vitamin D  $\geq 20$  ng/mL)
  - Vitamin D 800 to 4,000 IU/day D<sub>2</sub>/D<sub>3</sub> (6)[A]
  - D<sub>3</sub> (animal derived) may be slightly more effective than D<sub>2</sub> (plant derived), but clinical significance is uncertain.
  - Calcium supplementation: Unclear benefit and may increase some CHD risk in patients. No supplementation currently required (see below).
- Vitamin D deficiency (25-OH vitamin D <20 ng/mL)
  - D<sub>2</sub> 50,000 IU/week for 8 to 12 weeks, followed by 800 to 2,000 IU/day of vitamin D<sub>3</sub> (6)[A]
- Calcium: meta-analysis data support
  - Dietary intake of  $\approx 700$  mg/day leads to best outcomes; higher doses did NOT decrease risk of osteoporotic fractures.
  - Dietary calcium may be more beneficial than calcium supplementation.
  - Supplementary calcium associated with an increased risk of MI, especially in women (7)[A], but this data remains controversial (8)[C].

## **ISSUES FOR REFERRAL**

Endocrinology if no response to treatment

## **ADDITIONAL THERAPIES**

Aggressive calcium in ICU patients with ionized calcium <3.2 mg/dL or if symptomatic (tetany, seizures, QT prolongation, bradycardia, or hypotension, or ventilated patient with decreased diaphragmatic function)

## **INPATIENT CONSIDERATIONS**

### **Admission Criteria/Initial Stabilization**

- Symptoms of severe hypocalcemia *or*
- Malabsorption syndromes

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

Follow-up of abnormal 25-OH vitamin D not required

### DIET

- Cod liver oil is most potent source of vitamin D and has  $\div$  1,300 IU vitamin D/tablet/tablespoon.
- Fatty fish (tuna, salmon)
- Fortified milk (100 IU/8 oz), cereal, and foods

### PROGNOSIS

- Systematic review of 63 observational studies found adequate 25-OH vitamin D levels correlate with lower rates of colon, breast, and prostate cancer.
- Cohort study found that vitamin D deficiency is correlated with increased risk of all-cause mortality.

### ALERT

Meta-analysis data support supplementation of  $>500$  IU/day lowered the risk of all-cause mortality (5,9)[A] but remains controversial.

## Codes

**&NA;**

### ICD10

- E55.9 Vitamin D deficiency, unspecified
- M83.8 Other adult osteomalacia

## Clinical Pearls

**&NA;**

- Risk factors for VDD: senior citizen, renal disease, GI (malabsorption) disorders, liver dysfunction, immigration from tropical to colder climates, darkskinned/veiled individuals, housebound patients, perimenopause
- Diagnosis: 25-OH vitamin D (most sensitive measure of vitamin D status)
- Vitamin D deficiency: <20 ng/mL

- Up to 4,000 IU/day is safe in healthy adults without risk of toxicity.
- 2005 and 2009: Meta-analysis demonstrated for ages 51 to 70 years minimally recommended supplementation is 800 IU/day to prevent nonvertebral fractures.
- The American Academy of Pediatrics recommends all breast-fed babies receive 400 IU/day of vitamin D beginning within a few days of birth.

# Vitamin Deficiency

Michelle E. Szczepanik, MD

Christopher D. Meyering, DO

## BASICS

### *DESCRIPTION*

- Vitamins are essential micronutrients required for normal metabolism, growth, and development.
- Deficiencies are less common in the Western world but certain populations are at increased risk.
- Regulations mandating vitamin supplementation in food products, adequate food supply, and availability of vitamin supplements all make vitamin deficiencies in the Western world lower.
- Toxicity is rare in water-soluble vitamins; however, is possible with fat-soluble vitamins (A, D, E, K).

### *EPIDEMIOLOGY*

#### *Incidence*

- Predominant age
  - Geriatric population, pregnant women, exclusively breastfed infants, and individuals with certain chronic disease states
- Individuals from Africa and Southeast Asia are at increased risk.
- True incidence is unknown as most vitamin deficiencies are asymptomatic.

#### *Prevalence*

- Varies by age groups, comorbid conditions, geography, and setting (i.e., urban, rural)
- The prevalence of vitamin B<sub>12</sub> deficiency is around 6% in those <60 years of age but increases to around 20% after the age of 60 (1).
- Vitamin D deficiency has become increasingly recognized and its prevalence is increased in individuals with darker skin pigmentation, obesity, low dietary intake of vitamin D, or low

sunlight exposure.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Deficiencies usually related to disease can develop under healthy conditions and generally occur due to 1 of 5 mechanisms:
  - Reduced intake
  - Diminished absorption
  - Increased use
  - Increased demand
  - Increased excretion
- Chronic disease states: HIV, malabsorption (such as celiac sprue and short bowel syndrome), chronic liver and kidney disease, alcoholism, malignancies, pernicious anemia, and rare inborn errors of metabolism
- Bariatric surgeries: gastric bypass, gastrectomy, small or large bowel resection
- Predisposition related to certain drugs: prednisone, phenytoin, isoniazid, protease inhibitors, methotrexate, phenobarbital, alcohol, nitrous oxide, H<sub>2</sub> receptor antagonists, metformin, colchicine, cholestyramine, 5-fluorouracil, 6-mercaptopurine, azathioprine, chloramphenicol, proton pump inhibitors, chronically used antibiotics, penicillamine, and hydralazine
- Malnutrition, imbalanced nutrition, obesity, fad diets, extreme vegetarianism, total parenteral nutrition, bulimia/anorexia, and other eating disorders
- Dialysis
- Parasitic infestation

## *Genetics*

- Cystic fibrosis
- Hartnup disease
- Rare genetic predisposition
  - Autoimmune disease (e.g., pernicious anemia)
  - Congenital enzyme deficiencies (e.g., biotinidase or holocarboxylase synthetase deficiency)
  - Transcobalamin II deficiency
  - Ataxia and vitamin E deficiency (AVED)

- A-*and*-lipoproteinemia

## RISK FACTORS

Poverty, malnutrition, chronic disease states, advanced age, dietary restrictions, bariatric surgery, and exclusively breastfed infants

## GENERAL PREVENTION

- Ingesting large and varied amounts of vitamins increases risk of toxicity and drug-drug interactions.
- Antioxidant supplement use has not been shown to impact cancer incidence and, in some studies, has *increased* risk of death (2).
- Avoidance of restrictive diets decreases the likelihood of vitamin deficiency.
- In particular age groups or with certain risk factors, vitamin supplementation may be recommended.
- U.S. Preventive Services Task Force (USPSTF) recommends vitamin D supplementation in communitydwelling adults aged 65 years or older who are at increased risk for falls (3)[B].
- USPSTF recommends against low-dose supplementation with vitamin D (<400 IU) and calcium (<1,000 mg) to reduce fracture risk in noninstitutionalized populations and concluded that data on the effects of higher doses were insufficient (3).
- USPSTF recommends that all women planning or capable of pregnancy take a daily supplement containing 0.4 to 0.8 mg of folic acid (4)[A].
- USPSTF recommends against the use of beta carotene or vitamin E supplements for the prevention of cardiovascular disease or cancer (2).
- The American Academy of Pediatrics recommends that all infants and children, including adolescents, have a minimum daily intake of 400 IU of vitamin D beginning soon after birth (5).

## COMMONLY ASSOCIATED CONDITIONS

Anemia, neuropathies, dermatitis, visual disturbances

## DIAGNOSIS

### HISTORY

- Review dietary intake (6)
- Decreased visual acuity or night blindness (7)

- Poor wound healing or easy bruising (8)
- Skin changes or new rash (8)
- Neuropathy (6)
- Abnormal food cravings (pica)
- Osteomalacia or history of low-energy fracture (9)
- Previous birth of a child with spina bifida
- Previous GI or bariatric surgery (1)
- Recurrent or persistent vomiting or diarrhea
- Prior or current medical conditions
  - Tuberculosis (TB), HIV infection, hepatitis, cancer
  - Hypermetabolic state
    - Thyrotoxicosis
    - 2nd- or 3rd-degree burns
    - Extensive or chronic wound
    - Any systemic infection
- Chronic disease requiring steroids, disease-modifying antirheumatic drugs (DMARDs), or immunosuppressants
- Malabsorptive or chronic GI disorder: celiac disease, sprue, Crohn disease, ulcerative colitis, GERD
- Parenteral or enteral nutrition via tube feeding
- Pregnancy
- Amenorrhea or infertility issues (10)
- Medications, supplements
- Food allergies or intolerances, fad or restrictive diet

## *PHYSICAL EXAM*

- Neurologic exam: gait, memory/cognitive impairment, reflexes, sensory or motor impairment, peripheral neuropathy (1,6)
- Oropharyngeal exam to look for glossitis, bleeding gums, hyperemic pharynx, stomatitis, cheilitis (1)
- Skin exam to look for maculosquamous dermatitis, photosensitive pigmented dermatitis, ecchymosis and/or petechiae (6)
- Visual assessment

# DIFFERENTIAL DIAGNOSIS

Many conditions may mimic signs and symptoms of vitamin deficiencies.

- Diabetes mellitus (DM), thyroid disorders, hyperparathyroidism, heart failure, Alzheimer disease, multiple sclerosis, substance abuse, toxic ingestions, and hematologic disorders/malignancies

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- No routine screening indicated.
- Test if symptomatic or history indicates at high risk. If clinical characteristics are present, consider the following:
  - 25-OH vitamin D (5)
  - Prothrombin time (PT)/partial thromboplastin time (PTT)
  - Vitamin B<sub>12</sub> and folate levels (1)
  - Serum homocysteine and methylmalonic acid levels if high suspicion of vitamin B<sub>12</sub> deficiency with normal serum B<sub>12</sub> level (6)
  - Retinol serum level, retinol binding protein
- Ancillary tests include the following:
  - BUN, calcium, phosphorus, magnesium
  - Albumin, liver function tests
  - CBC
  - Parathyroid hormone
- Bone densitometry indicated in the following (11)[A]:
  - Women 65 years of age or older without previous known fractures or risk factors
  - Women <65 years old whose 10-year fracture risk is equal to that of a 65-year-old white woman without additional risk factors.
  - According to the United States fracture risk assessment tool (FRAX), the 10-year fracture risk for a 65-year-old white woman without risk factors is 9.3%.
- Give bariatric surgery patients additional consideration as they are at risk for deficiencies.

Laparoscopic gastric banding is less frequently associated with vitamin deficiencies (10).

- Cyanocobalamin, thiamine, vitamin A
  - Disease states from vitamin deficiency
    - Vitamin A (retinol): night blindness, complete blindness, xerophthalmia
    - Vitamin B<sub>1</sub> (thiamine)
      - Wernicke encephalopathy: acute syndrome with memory disturbance, truncal ataxia, nystagmus, ophthalmoplegia
      - Korsakoff syndrome: anterograde and retrograde amnesia, confabulation
      - Dry beriberi: symmetric motor and sensory peripheral neuropathy, paresthesias, loss of reflexes
      - Wet beriberi: neuropathy with cardiovascular symptoms of peripheral vasodilation, highoutput failure, dyspnea, and tachycardia
- 
- Infantile beriberi: loud piercing cry, cyanosis, tachycardia, cardiomegaly, dyspnea, vomiting, seizures
  - Vitamin B<sub>2</sub> (riboflavin): glossitis, stomatitis, cheilitis, hyperemia of the pharyngeal mucosal membranes, normocytic-normochromic anemia
  - Vitamin B<sub>3</sub> (niacin): pellagra: photosensitive pigmented dermatitis, dementia, and diarrhea
  - Vitamin B<sub>5</sub> (pantothenic acid): paresthesias and dysthesias, anemia
  - Vitamin B<sub>6</sub> (pyridoxine): dermatitis, cheilosis, atrophic glossitis, stomatitis, neuropathy
  - Vitamin B<sub>9</sub> (folate): megaloblastic anemia, rarely manifest neurologic symptoms
  - Vitamin B<sub>12</sub> (cobalamin): pernicious anemia, shuffling broad-based gait, atrophic glossitis, loss of vibration and position sense, cognitive impairment
  - Vitamin C (ascorbic acid): scurvy: ecchymoses, bleeding gums, petechiae, hyperkeratosis, arthralgias, impaired wound healing
  - Vitamin D (calciferol): rickets, osteomalacia
  - Vitamin E: neuromuscular disorders and hemolysis
  - Vitamin K: easy bruising, mucosal bleeding, melena, hematuria
  - Biotin: changes in mental status, dysesthesias, nausea, maculosquamous dermatitis of the extremities

P.1125

## TREATMENT

### MEDICATION

- Ask patients about any herbal or dietary supplements and encourage them to bring in vitamin and supplement bottles for review.
- Assess for potential adverse drug effects/reactions. Patients with alcohol dependence should receive thiamine, folic acid, and MVI.
- Treat patients with suspected thiamine deficiency with 100 mg thiamine prior to IV fluids containing glucose to prevent precipitation of Korsakoff psychosis (10).
- If there is concomitant B<sub>12</sub> and folate deficiency, then start B<sub>12</sub> first to avoid precipitating subacute combined degeneration of the spinal cord (1).
- Consider obtaining prealbumin/albumin levels and a dietary consult for malnourished patients.
- Bariatric surgery patients will need lifelong vitamin supplementation; there are no consensus practice guidelines for supplement dosing regimens (12)

### Geriatric Considerations

- Vitamin B<sub>12</sub> deficiency exists in around 20% of the general population <sup>3</sup>60 years of age. Treat symptomatic or severe deficiency with an intramuscular (IM) injection of cyanocobalamin 1,000 &mgr;g/day 3 times a week for 2 weeks. If there are neurologic symptoms then give the same dose of cyanocobalamin every other day for 3 weeks or until symptoms have resolved. To prevent recurrence or treat mild deficiency, use a regimen of oral B<sub>12</sub> 1,000 &mgr;g/day or an IM injection of B<sub>12</sub> 1,000 &mgr;g every month (6). Low-dose oral therapy with 50 to 150 &mgr;g/day may be considered for mild cases (1). High-dose (1,000 to 2,000 &mgr;g/day) oral treatment is as effective as monthly IM injections, but use caution in patients with malabsorption or compliance issues (1,6)[C].
- >40% of elderly in United States are vitamin D deficient. Deficiency is defined as a serum 25-OH vitamin D level of <20 ng/mL. Treatment of vitamin D deficiency is 50,000 IU of oral ergocalciferol weekly for 8 weeks (3,10,13)[B].

### Pediatric Considerations

- Vitamin K deficiency bleeding (9)
  - Neonates may exhibit signs of vitamin K deficiency because they require 1 week of life to establish intestinal flora which manufactures vitamin K.

- Condition peaks 2 to 10 days after birth: bleeding from the umbilical stump and/or circumcision site, generalized bruising, and GI hemorrhage
- Infrequent in developed countries due to routine injection of newborns with vitamin K (1 mg)
- Vitamin D deficiency: Vitamin D supplementation (400 IU/day) is recommended in all exclusively breastfed infants starting in the first few days of life (5)[A].
- All nonbreastfed infants and older children drinking <1,000 mL/day of vitamin D-fortified formula or milk should receive a vitamin D of 400 IU/day (5).
- Adolescents may receive a vitamin D supplement of 400 IU/day (5).
- Morbidly obese and minority children are at increased risk for vitamin D deficiency (14).
- In children age >6 months in developing countries, vitamin A supplementation has been shown to decrease mortality (7)[B].
- Vitamin deficiency associated with developmental delay.

## *Pregnancy Considerations*

All pregnant women and women of childbearing age considering pregnancy are strongly encouraged to take a multivitamin containing at least 0.4 mg folic acid daily to prevent neural tube defects (4)[A].

## **ONGOING CARE**

### *DIET*

Vitamins are best utilized by the body from food intake. Supplements should be used where it is not feasible to ingest the recommended amount of a particular vitamin.

### *PATIENT EDUCATION*

- In healthy adults, multivitamins have no value in a patient with an adequate diet and may increase risk of some cancers.
- Drug-drug interactions may occur between vitamins and some medications. Patients should report all supplements along with medications to their health care provider.
- Risk of vitamin toxicity occurs most commonly with the fat-soluble vitamins (A, D, E, K).

### *PROGNOSIS*

Most vitamin deficiencies are fully reversible if treated without undue delay.

## COMPLICATIONS

- Vitamin toxicities
- Liver failure (vitamins A, D, E, K)
- Desquamation of skin (vitamin A)
- Neuropathy (vitamin B<sub>6</sub>)
- Kidney stones (vitamin C, vitamin D)
- Hypercoagulability (vitamin K)
- Pseudohyperparathyroidism (vitamin D)
- Masking of pernicious anemia (folic acid)

## Codes

&NA;

### ICD10

- E56.9 Vitamin deficiency, unspecified
- E56.0 Deficiency of vitamin E
- E55.9 Vitamin D deficiency, unspecified

## Clinical Pearls

&NA;

- Obtain a thorough dietary history.
- Specifically ask patients about supplement use.
- Vitamin D supplementation is recommended in community-dwelling adults aged 65 years or

older who are at increased risk for falls (3). All women planning or capable of pregnancy should take a daily supplement containing 0.4 to 0.8 mg of folic acid (4). All infants and children, including adolescents, should have a minimum daily intake of 400 IU of vitamin D beginning soon after birth (5).

# Vitiligo

**Sonia Rivera-Martinez, DO, FACOFP**

**Karen Sheflin, DO**

## BASICS

### DESCRIPTION

- An acquired depigmentation of the skin, which correlates with a loss of epidermal melanocytes. There are three clinical variants, each with subtypes.
- Localized: often in childhood, rapid onset then stabilizes. Involvement of hair is common early in the course. Lacks associated autoimmune diseases.
  - Focal: few lesions, random distribution
  - Segmental: Lesions occur within a dermatome (mostly trigeminal) or may follow Blaschko lines. Lesions usually stop abruptly at the midline (1).
  - Mucosal: Only mucosal surfaces involved
- Generalized/nonsegmental (most common variant): progressive, with flares, commonly associated with autoimmunity. Common locations are acral, periorificial, and in sites sensitive to pressure/friction (Koebner phenomenon) (1).
  - Vulgaris: most common subtype; scattered macules; often symmetric, wide distribution; mostly hands, axillae, and groin
  - Acrofacial: on distal extremities and face
  - Mixed: coexistence of above
- Universal: involves >80% of the body surface area (BSA). Most likely to have family history; comorbidities are common and associated with poorest quality-of-life (QOL) scores.
- Other rare variants
  - PonctuŹ: discrete confetti-like macules (1)
  - Inflammatory: peripheral erythematous rim (1)
  - Trichrome: Tan zone is present between normal and depigmented skin (1).
  - Quadrichrome: as above but with marginal/perifollicular hyperpigmentation (1)

- Blue: Dermal melanophages give blue hue, in areas affected by prior postinflammatory hyperpigmentation (1).
- System(s) affected: skin, mucous membranes
- Synonym(s): leukoderma

## *EPIDEMIOLOGY*

- 50% begin before age 20 years, peak in females: 1st decade; males: 5th decade. Onset earlier with positive family history; can appear as early as 6 weeks (1).
- Predominance: male = female; however, females are more likely to seek treatment (1).
- No race or socioeconomic predilection

## *Prevalence*

÷1% in the United States and Europe; 0.1-8% in the world; highest in Gujarat, India, at 8.8% (1)

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Most likely a spectrum of disorders with a common phenotype and multiple mechanisms contribute to the pathology (convergence theory).

- Genetic: see above.
- Autoimmune: humoral autoantibodies and skinhoming T cells (1)
- Neural: local or systemic dysregulation leading to excess neurotransmitters (1)
- Viral: direct melanocyte toxicity, cytomegalovirus (CMV), hepatitis C, and Epstein-Barr virus (EBV) found in lesional biopsies (1)
- Oxidative stress from elevated H<sub>2</sub>O<sub>2</sub> and NO and decreased catalase and erythrocyte glutathione (1)

## *Genetics*

- Polygenic/multifactorial inheritance
- 20% of patients report affected relative, but monozygotic twins have only 23% concordance.
- HLA haplotypes, small nucleotide polymorphisms, and specific genes are all possible contributors (1).

## *RISK FACTORS*

- Family history of vitiligo/autoimmune disorders

- Personal history of associated conditions

## COMMONLY ASSOCIATED CONDITIONS

- Most common
  - Endocrine: thyroid disease (hypo-/hyperthyroidism), hypoparathyroidism, Addison disease, insulindependent diabetes
  - Dermatologic: psoriasis, atopic dermatitis, alopecia areata, chronic urticaria, halo nevi, ichthyosis
  - Pernicious anemia
  - Hypoacusis, rheumatoid arthritis
  - Ocular abnormalities in up to 40%
  - Elevated antinuclear antibodies in up to 40%
  - Elevated thyroperoxidase antibodies in 50%
- Less common
  - Systemic lupus erythematosus
  - Inflammatory bowel disease
  - Melanoma (may be a sign of positive outcome of melanoma) and other skin cancers
  - Syndromes: Alezzandrini; mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes (MELAS); Schmidt; and autoimmune polyendocrinopathy candidiasis ectodermal dysplasia (APCED)
- Age >50 years at onset should prompt investigation for associated conditions.

### *Pediatric Considerations*

Associated with Hashimoto thyroiditis in a significant portion of children. Screening at onset and possibly annually may be beneficial.

## DIAGNOSIS

### HISTORY

- Inquire about recent history of sunburns, pregnancy, skin trauma, or emotional stress (1).
- Family history of premature graying, vitiligo, and autoimmune disorders

- Review of systems for related associated conditions
- Ascertain psychological impact on QOL, Dermatology Life Quality Index (DLQI).

## *PHYSICAL EXAM*

- Full-body skin exam with Wood lamp to accentuate lesions and distinguish depigmentation from hypopigmentation (1)
- Lesions are well-demarcated, uniform white macules and patches.
- Look for evidence of repigmentation (most commonly around hair follicles).

## *DIFFERENTIAL DIAGNOSIS*

- Infectious: tinea versicolor, leprosy, leishmaniasis, onchocerciasis, treponematoses (pinta/syphilis)
- Postinflammatory hypopigmentation: psoriasis, atopic dermatitis, pityriasis alba, systemic lupus erythematosus, scleroderma
- Inherited hypomelanoses: piebaldism, tuberous sclerosis, Waardenburg, hypomelanosis of Ito, Vogt-Koyanagi-Harada
- Malformations: nevus anemicus, nevus depigmentosus
- Paraneoplastic: mycosis fungoides, melanoma-associated leukoderma
- Occupational and chemical induced
  - Occupational: phenolic/catechol derivatives and arsenic-containing compounds
  - Chemical: numerous, including cosmetics, cleansers, insecticides, and even medications (imatinib, potent topical corticosteroids [TCS]) (1)
- Melasma: Normal skin may be confused as vitiligo in the setting of surrounding hyperpigmentation.
- Halo nevi
- Lichen sclerosus et atrophicus
- Idiopathic guttate hypomelanosis
- Progressive-acquired macular hypomelanosis

## *DIAGNOSTIC TESTS & INTERPRETATION*

## *Initial Tests (lab, imaging)*

- TSH, CBC, ANA (1)
- Consider antithyroid peroxidase, antithyroglobulin antibodies, hemoglobin, vitamin B<sub>12</sub> levels if family/patient history of autoimmune disease (1).

## *Follow-Up Tests & Special Considerations*

- Monitor for disease progression/flares.
- Monitor for symptoms of related conditions.

## *Diagnostic Procedures/Other*

- Skin biopsy is rarely needed. Highest yield is with comparison of lesional/perilesional biopsies.
- Consider ophthalmologic and audiologic evaluation.

## *Test Interpretation*

Few or no epidermal melanocytes. At margins, melanocytes may be larger, vacuolated, and dendritic. Early lesions show inflammation and later, degeneration, including of adnexa and nerves.

## **TREATMENT**

The variant of vitiligo may affect response.

- If untreated, progression is the natural course for those with mucosal involvement, family history, koebnerization, and nonsegmental variants.
- Lesions that respond best are on the face, of recent onset, in darker skin type, and in younger patients.

## **GENERAL MEASURES**

- Sunscreen to decrease sunburn and prevent accentuation of uninvolved skin
- Corrective camouflage as coverup (Cover FX, Dermablend)

## **MEDICATION**

- Individualize therapy depending on age, extent, distribution, and rate of progression.
- Many therapies are considered "off-label" and not FDA-approved for vitiligo, although they

are often considered first-line therapy.

- Corticosteroids: Mid-potency topical corticosteroids (mometasone furoate, fluticasone propionate) applied daily as monotherapy are considered first-line treatments. Do not use on face/axilla/groin; do not occlude except under close monitoring. Pediatric: as above, for children >12 years of age. Consider decreased potency. Local side effects including atrophy, telangiectasia, hypertrichosis, acneiform eruptions, and striae limit treatment; regular steroid holidays are recommended (2). The combination of light therapy and TCS is the most effective treatment overall (3). Most efficacious on sun-exposed areas: face/neck, dark-skinned patients, newer lesion (3). Addition of tretinoin 0.025-0.05% BID is effective and can decrease potential skin atrophy (4). Systemic corticosteroids can be helpful, but dosage and safety parameters have not been fully evaluated (2,5)[A].

P.1127

- Topical calcineurin inhibitors: slightly inferior to TCS as monotherapy but better side effect profile (3,6,7)[B]; can be used as adjunctive to light therapy; carries a controversial black box warning for a theoretical risk of lymphoma or skin cancer. Extensive safety profiling has not revealed any evidence for this in children or adults using topical calcineurin inhibitors. Local reactions include burning sensation, pruritus, erythema, and rare transient hyperpigmentation (3).
  - Tacrolimus 0.03% or 0.1% ointment BID (2). Pediatric: 0.03% ointment BID, for children >2 years of age (7)
  - Pimecrolimus 1% cream BID (2). Pediatric: as adults, for children >2 years of age (7)
- Topical vitamin D<sub>3</sub> analogs: less effective than TCS alone, but in combination with TCS or phototherapy can shorten time until, and improve stability of, repigmentation (5,7)[B].
  - Calcipotriene ointment 1 to 2 times per day. Pediatric: not defined.
  - Available as a combination formulation, betamethasone dipropionate 0.064%/calcipotriene 0.005% ointment daily, max dose of 100 g/week for 4 weeks, not for >30% BSA, and not for face/axilla/groin. Pediatric: not defined.
- Oral vitamin D<sub>3</sub>: reported to induce repigmentation. Oral vitamin D<sub>3</sub> 35,000 U once daily plus lowcalcium diet for 6 months. Pediatric: not defined.
- Phototherapy: Narrow band UVB (NBUVB) is superior to UVA and indicated for lesions involving more than 15-20% BSA (5,7,8)[A]. Psoralen and khellin enhance the effect of light. Psoralen plus UVA (PUVA) may increase the incidence of skin cancers. Khellin may have reduced cross-linking of DNA and may be less carcinogenic; however, it is associated with increased liver toxicity (8). L-phenylalanine can be used topically and orally as a photosensitizer for natural or artificial light. Pediatric: Oral PUVA is contraindicated.

- Laser therapy: Excimer laser (308 nm) is superior to other light therapy. Helium-neon laser works for segmental vitiligo (7)[A].
- Antioxidants: may have protective role in preventing melanocyte degradation from reactive oxygen species. Options include vitamin C, vitamin E, Vitix, *Polypodium leucotomos* extracts, and *Ginkgo biloba* (6)[B].
- Surgical therapy: See later discussion.
- New concepts: Tumor necrosis factor- $\alpha$  inhibitors, cyclosporine, cyclophosphamide, azathioprine, minocycline, and immunosuppressants are currently being evaluated (8).

### *First Line*

- Recommended: avoidance of triggering factors plus TCS alone or in combination with NBUVB
- Alternatively
  - Topical calcineurin inhibitors (preferred for face, neck, axilla, and groin)
  - NBUVB
  - PUVA in adults
  - Camouflage and psychotherapy should be offered to all patients at any stage (8).

### *Second Line*

- Recommended: photochemotherapy with psoralens or vitamin D analogues
- Alternatively
  - Topical vitamin D analogues
  - Targeted phototherapy
  - 308-nm laser in combination with topical steroids, topical calcineurin inhibitors, or vitamin D analogues
  - Oral corticosteroids (pulse therapy)
  - Surgical treatments indicated for stable 2- to 3-cm lesions, refractory to other treatments
    - Mini-punch graft (pretreat with cryotherapy/dermabrasion or posttreat with phototherapy) (9)[B]
    - Suction blister graft (9)[B]
    - Autologous melanocyte suspension transplant (6)[B]

## ISSUES FOR REFERRAL

- Dermatologist: for facial/widespread vitiligo or when advanced therapy is necessary
- Ophthalmologist: for ocular symptoms or monitoring of TCS near eyes
- Endocrinologist: evaluation/management of associated conditions
- Psychologist: for severe distress
- Medical geneticist for associated conditions

## ADDITIONAL THERAPIES

- Depigmentation therapy with monobenzene, hydroquinone, or Q-switched ruby laser: for extensive vitiligo recalcitrant to therapy (9)
- Pseudocatalase with addition of NBUVB (2)[B]
- Prostaglandin E for short-duration disease and localization to face and scalp (2)[B]
- Cosmetic tattooing for localized stable vitiligo

## SURGERY/OTHER PROCEDURES

- Goal is to transport melanocytes from other areas of the skin. Methods include punch, blister, or split-thickness skin grafting, or transplantation of autologous melanocytes.
- Dermabrasion and curettage alone or in combination with 5-fluorouracil may induce follicular melanocyte reservoirs (7)[A].
- Patients who koebnerize or form keloids may be worse, and permanent scarring is a risk for all patients.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- *Ginkgo biloba* 60 mg PO daily may significantly improve extension and spreading of lesions (8) [B].
- *Polypodium leucotomos* may help with repigmentation with NBUVB and aid in reducing phototoxic reactions (7,8)[B].

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

- Monitor for symptoms of related conditions.

- With topical steroids, follow at regular intervals to avoid steroid atrophy, telangiectasia, and striae distensae.

## DIET

No restrictions

## PATIENT EDUCATION

- Discussion of disease course, progression, and cosmesis
- Education regarding trauma/friction and Koebner phenomenon

## PROGNOSIS

- Vitiligo may remain stable or slowly or rapidly progress.
- Spontaneous repigmentation is uncommon.
- Generalized vitiligo is often progressive, with flares. Focal vitiligo often has rapid onset, then stabilizes.

## COMPLICATIONS

- Adverse effects of each treatment modality
- Psychiatric morbidity: depression, adjustment disorder, low self-esteem, sexual dysfunction, and embarrassment in relationships (1)
  - Different cultures may have different perceptions/social stigmas about vitiligo. Some believe it to be contagious or related to infection. Women with vitiligo may have difficulty finding a marriage partner and have low self-esteem.

&NA;

## ICD10

L80 Vitiligo

## Clinical Pearls

&NA;

- Vitiligo can be a psychologically devastating skin disease.
- Screen for associated diseases, particularly if onset occurs later in life.
- Treatment should be individualized based on BSA, skin type, and patient goals.
- Dermatology consultation when extensive disease, facial involvement, and when advanced treatments are considered.

# Vocal Cord Dysfunction

Daniel A. Cieslak, MD

Emily M. Culliney, MD, FAAFP

## BASICS

### DESCRIPTION

- Vocal cord dysfunction (VCD): a breathing disorder in which vocal cords adduct inappropriately primarily on inspiration, producing airflow obstruction that may result in dyspnea, wheezing, and stridor
- Synonym(s): paradoxical vocal fold motion (PVFM)

### EPIDEMIOLOGY

#### *Incidence*

Not well defined

#### *Prevalence*

- Unknown; likely uncommon in the general population
- Most frequently diagnosed in patients evaluated for asthma and exercise-induced dyspnea
- Female predominance, 2:1 (1)
- 71% of patients are adults and 29% of patients <18 years of age. Also has been diagnosed in young children/infants (1)
- Suspect occurrence in approximately 3% of intercollegiate athletes with exercise-induced asthma (2).

### ETIOLOGY AND PATHOPHYSIOLOGY

- Exact etiology is unclear—both organic and nonorganic causes have been identified.
- Possible laryngeal hyperresponsiveness to irritants, such as smoke, dust, postnasal drip, gastroesophageal reflux disease (GERD), URI, or other irritants (3)
- Noncompetitive and competitive exercises—unknown mechanism (4)

- Psychological factors such as anxiety, severe social stresses (e.g., competitive sports), history of sexual abuse (2)

## *Genetics*

None defined

## **RISK FACTORS**

See "Commonly Associated Conditions."

## **COMMONLY ASSOCIATED CONDITIONS**

- Asthma
- GERD
- Rhinosinusitis
- Psychological conditions such as posttraumatic stress disorder, anxiety, depression, and panic disorder

## **DIAGNOSIS**

### **HISTORY**

- Recurrent episodes of "difficulty breathing in," wheezing, throat or chest tightness, choking sensation, stridor, panic, and agitation
- Stridulous sounds that are loudest above the throat, less audible throughout the chest wall.
- Some patients (typically elite athletes) experience inspiratory stridor that resolves spontaneously when activity ceases.
- The stridor is often mistaken for wheezing, leading to misdiagnosis of asthma or exercise-induced asthma.
- Dysphonia or aphonia is possible between attacks.
- History of multiple ED visits, possibly multiple intubations
- The symptoms tend to be relatively mild but can be prolonged and severe.
- Patients may report their asthma medications do not help their symptoms.

## **PHYSICAL EXAM**

- Inspiratory stridor

Cough

- Wheezing (especially if unresponsive to bronchodilators)
- Mild respiratory distress

## ***DIFFERENTIAL DIAGNOSIS***

- Asthma: primary differential diagnosis because wheezing is a big component—although VCD can coexist with asthma (1,2). The key differences between the two are the following:
  - Asthma typically has wheeze on expiration, VCD on inspiration.
  - Asthma symptoms associated with nocturnal awakenings, uncommon in VCD
  - Asthma is not typically associated with a sensation of choking.
  - Asthma symptoms usually improve with albuterol use (3).
  - VCD causes more difficulty with inspiration rather than expiration.
  - VCD is not responsive to asthma treatment (unless coexisting) (2).
- Anaphylaxis
- Foreign body
- Laryngeal angioedema
- Chronic obstructive pulmonary disease
- Epiglottitis
- Vocal cord polyps/tumor
- Vocal cord paralysis
- Croup
- Tracheal stenosis or masses
- Laryngomalacia (1)
- Neurologic cause: vagus or recurrent laryngeal nerve injury, amyotrophic lateral sclerosis (3)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Flexible laryngoscopy—gold standard (2)[C]
  - Allows for direct visualization of abnormal adduction of the vocal cords

- May allow for diagnosis in more than half of asymptomatic patients; however, provocation tests such as methacholine (5), exercise (4), and histamine may be needed for diagnosis (4,5)[C].

- Pulmonary function testing with flow volume loop
  - Most commonly used test
  - Positive findings consist of normal expiratory volume loop with a flattened inspiratory volume loop. This is consistent with extrathoracic upper airway obstruction (6)[C].
  - May require exercise testing for patients in whom exercise is the trigger
  - Useful for distinguishing from asthma, which may show a scooped expiratory loop
- Imaging
  - Chest radiographs to rule out other causes of dyspnea (2)
  - High-resolution CT of upper airways to evaluate for stenosis, masses (if not able to visualize trachea during laryngoscopy) (7)
- Arterial blood gases
  - Useful to rule out other causes of severe respiratory distress

## TREATMENT

### GENERAL MEASURES

- Short term
  - Asthma control/treatment with appropriate meds, if coexisting (3)[C]
  - Reassurance and relaxation techniques:
    - Pursing lips
    - Panting (rapid, shallow breathing)
    - Diaphragmatic breathing
    - Breathing through the nose or a straw
    - Exhaling with a hissing sound
  - Continuous positive airway pressure (CPAP)

- Intermittent CPAP with heliox (helium-oxygen) mixture may reduce airway resistance in some patients (1,2)[C].
- Anxiolytics if associated with anxiety attack (must confirm normal oxygen saturation prior to administration)
- Intubation with severe symptoms (3)[C]
- Long term
  - Avoid triggers.
  - Behavioral speech/voice therapy (8)[B]
  - Treat underlying conditions.

## MEDICATION

### First Line

No medications are specifically helpful. Exercise-induced VCD may respond to anticholinergics in addition to speech therapy; thus, consider a trial of ipratropium if symptoms are exercise-induced (9)[C].

## ISSUES FOR REFERRAL

- Diagnosis and treatment may require assistance of pulmonologist, otolaryngologist, allergist, psychiatrist, and/or psychologist.
- Speech therapy is the mainstay of long-term treatment for patients with ongoing symptoms. It helps reduce recurrence.

## ONGOING CARE

### PROGNOSIS

Spontaneous resolution is common.

# Codes

**&NA;**

## ICD10

- J38.3 Other diseases of vocal cords
- J38.00 Paralysis of vocal cords and larynx, unspecified
- J38.1 Polyp of vocal cord and larynx

## Clinical Pearls

**&NA;**

- Always consider VCD in poorly controlled asthmatics.
- A multidisciplinary approach may be required for diagnosis and treatment.
- Speech therapy is the mainstay of long-term treatment.

# Von Willebrand Disease

Aneel A. Ashrani, MD, MS

Ewa M. Wysokinska, MD

## BASICS

### DESCRIPTION

- von Willebrand disease (vWD) is a bleeding disorder caused by deficiency or a defect of *von Willebrand factor* (vWF) protein.
- vWF is critical to the initial stages of blood clotting, acting as a bridge for platelet adhesion; it also acts as a carrier for factor VIII (FVIII).
- vWD primarily manifests as mucocutaneous or perioperative bleeding or menorrhagia.
- vWD is an inherited condition but rarely can be acquired (1,2,3).

### EPIDEMIOLOGY

#### Prevalence

- Prevalence of the inherited forms of vWD is 1 in 100 to 10,000 of the general population with 2:1 female-to-male ratio (1).
- Exact prevalence of the acquired forms of vWD (AvWD) is unknown but is estimated to be up to 0.1% of the general population.

#### Pediatric Considerations

Many cases of vWD are diagnosed in childhood, often during initial years of menstruation. vWD may be difficult to diagnose before 6 months of age.

#### Pregnancy Considerations

Although levels of vWF increase during pregnancy, women with vWD are more likely to experience an increased incidence of obstetric complications that manifest with bleeding.

### ETIOLOGY AND PATHOPHYSIOLOGY

- vWF is a large, multimeric protein that is released from endothelial cells and is also carried

within platelets in  $\alpha$ -granules.

- vWF binds to collagen at sites of vascular injury and creates a surface for platelet adhesion through GP1b receptor. This results in platelet plug formation.
- vWF is also a carrier for FVIII and stabilizes this factor from degradation. A deficiency in vWF may result in lower levels of FVIII.
- When vWF is deficient or dysfunctional, primary hemostasis is compromised, resulting in increased mucocutaneous and postprocedural bleeding.
- Three major categories of vWD exist
  - Type 1, the most common and mildest form, represents 60-80% of cases.
    - Mild to moderate quantitative deficiency of vWF and concordant deficiency of FVIII
    - Generally, a mild bleeding disorder
  - Type 2 caused by qualitative defect in vWF accounts for 10-30% of cases and is divided into the following multiple subtypes.
    - Type 2A is noted for loss of hemostatically active large multimers with low ristocetin cofactor/vWF activity.
    - Type 2B, noted for increased binding affinity for platelets, is associated with thrombocytopenia, low ristocetin cofactor/vWF activity, abnormal ristocetin-induced platelet aggregation (RIPA), and loss of large multimers.
    - Type 2M is noted for defective platelet or collagen binding without loss of large multimers.
    - Type 2N demonstrates defective binding to FVIII, which results in increased clearance of Factor VIII and hemophilia A-like picture
  - Type 3 represents 1-5% of cases.
    - Most severe form characterized by markedly decreased-to-undetectable levels of vWF and FVIII
    - Manifests as hemophilia A with hemarthroses (1,2,3,4)
- Acquired form of vWD (AvWD) may be due to cardiovascular, hematologic, or autoimmune conditions, as well as tumors and medications.
- The pathophysiology of AvWD is related to the underlying cause and may result from shear induced cleaving of vWF in cardiovascular conditions, increased adsorption of vWF by certain tumor cells or activated platelets, or presence of anti-vWF autoantibodies detected in hematologic disorders.

## *Genetics*

- The 175-kb gene for vWF is located on short arm of chromosome 12.
- Type 1 follows an autosomal dominant inheritance pattern, with variable expressivity.
- Type 2 varies but primarily follows an autosomal dominant inheritance pattern.
- Type 3 follows an autosomal recessive inheritance pattern (4).

## **COMMONLY ASSOCIATED CONDITIONS**

AvWD may be found in patients with hematologic disorders such as MGUS and myeloproliferative neoplasms. Commonly associated cardiovascular conditions include aortic stenosis and LVAD placement.

## **DIAGNOSIS**

### **HISTORY**

- Most patients with vWD have a positive family history of bleeding disorder; however, patients with mild forms of vWD and their families may be unaware of their disease. Those with acquired vWD usually have no family history of this disorder.
- The most important component of diagnosis is the hemostatic history often aided by specifically designed bleeding questionnaires.
- Common symptoms are those of mucocutaneous (recurrent epistaxis, menorrhagia, ecchymosis) or postprocedural bleeding. Hemarthroses are a rare presentation, mostly associated with types 2N and 3.

## **PHYSICAL EXAM**

- Physical exam may be entirely normal, although there may be some ecchymoses.
- Findings suggestive of other causes of increased bleeding should be sought (liver disease, skin laxity, or telangiectasias).

## **DIFFERENTIAL DIAGNOSIS**

- Primary hemostatic disorders: congenital thrombocytopenia or qualitative platelet defects, coagulation factor deficiencies
- Secondary hemostatic disorders: liver disease, uremia, connective tissue disorders, coagulation factor inhibitors

# DIAGNOSTIC TESTS & INTERPRETATION

## Initial Tests (lab, imaging)

- The specific tests for vWD include vWF antigen (vWF:Ag), vWF activity/ristocetin cofactor activity (vWF:RCo) (if available: collagen-binding activity [vWF:CB]) and FVIII activity; these tests should be ordered when suspicion for vWD is high. Additional specific tests include RIPA, vWF multimer analysis, vWF propeptide (vWFpp), and genetic testing.
- Other tests include CBC, PT/INR, aPTT, platelet function analyzer assay (PFA-100).
  - Platelet count is often normal, except in type 2B or in AvWD when there is an underlying myeloproliferative disorder.
  - Platelet function assays via PFA-100 (i.e., collagen/epinephrine and collagen/ADP closure time) are usually prolonged but may be normal in mild disease.
  - PT/INR is normal, unless there is concurrent liver disease or warfarin/Coumadin use.
  - Activated PTT may be prolonged if a decrease in FVIII accompanies vWD.
- Specific tests for vWD
  - vWF antigen testing is done via immunologic methods
    - vWF antigen testing has a positive predictive value (PPV) of 33% for detecting significant FVIII deficiency and a PPV of 80% for detecting ristocetin cofactor activity abnormalities.
    - vWF antigen may be normal in type 2 vWD.
  - Ristocetin cofactor activity is a functional assessment of vWF. Ristocetin promotes binding of platelets to vWF, and this activity is disproportionately reduced compared to vWF antigen in most forms of type 2 vWD.
  - Ratio of vWF:RCo to vWF:Ag  $<0.5$  to  $0.7$  may be used to differentiate type 1 from type 2 vWD.
  - Alternatively, latex particle-enhanced immunoassay may be used to quantify vWF activity. A specific monoclonal anti-vWF antibody directed against platelet GP1b-binding site of vWF adsorbed onto the latex reagent reacts with plasma vWF proportional to the vWF activity.
  - Collagen-binding activity, another functional assessment of vWF, is reduced in most forms of vWD.
  - FVIII activity may be normal or mildly decreased in most types of vWD (in 2N and type 3, levels are markedly decreased).
  - vWFpp is useful in accelerated clearance variants of vWD.

- vWF multimer analysis is performed by electrophoresis on agarose gel. This test differentiates patients with type 2 vWD.
- RIPA is useful in diagnosing type 2B vWD.
- FVIII-vWF binding assay activity is low in patients with type 2N vWD.
- Genotype testing may also be used especially for types 2 and 3 (1,2,3,4).

## *Follow-Up Tests & Special Considerations*

- Unless patients have severe forms of vWD or are undergoing treatment, follow-up laboratory studies are not usually obtained.
- Patients with blood group O have 20-30% baseline lower levels of vWF antigen and ristocetin cofactor activity.
- vWF is an acute-phase reactant, so elevations may be seen in inflammatory conditions, liver disease, pregnancy (which may correct mild deficits), or with estrogen use.

## **TREATMENT**

### *GENERAL MEASURES*

- Most patients with type 1 vWD do not require activity restrictions.
- Patients with type 3 vWD should avoid contact sports.
- An emergency ID bracelet may be useful.

P.1131

### *MEDICATION*

#### *First Line*

- Desmopressin (DDAVP)
  - Enhances release of vWF from endothelial cells
  - Primarily effective for type 1 vWD; not to be used in type 2B
  - Typically raises vWF by 2- to 3-fold from baseline levels (5)[B]
  - Not effective in severe deficiencies, in types of vWD with defective vWF, or for prophylaxis prior to major procedures
  - Dosed 0.3 &mgr;g/kg (max 20 mg) IV/SC; intranasal (high concentration) spray: <50 kg:

150  $\mu$ g/day; >50 kg: 300  $\mu$ g/day (Stimate)

- Common side effects: flushing, tachycardia, water retention, hyponatremia
  - Obtain repeat testing of ristocetin cofactor activity and FVIII 1 and 4 hours after infusion to evaluate peak response and clearance of DDAVP.
  - Tachyphylaxis may develop with prolonged dosing; limit use to administering DDAVP once every 24 to 48 hours for 3 to 5 days.
- vWF and FVIII concentrates
    - Plasma-derived vWF and FVIII concentrates of various purity such as Humate-P, Alphanate, Wilate, or Fandhi (not available in United States) are commercial concentrates of vWF and FVIII that are given in doses of 25 to 60 IU/kg/day based on clinical situation (6,7)[B]
      - Administration of 1 IU/kg vWF:RCo concentrate raises the plasma RCo activity by approximately 2%.
      - Dose of vWF concentrate may be adjusted for FVIII levels and ristocetin cofactor activity.
      - FVIII levels should be monitored to avoid supranormal levels and possible venous thromboembolism (VTE).
      - Contraindicated if patient develops alloantibodies to vWF
    - New recombinant form of vWF concentrate is effective in clinical trials but not yet available for clinical use (8)[B].
    - In patients with severe bleeding phenotype, prophylactic treatment is used.
  - Cryoprecipitate
    - Cryoprecipitate contains FVIII, fibrinogen, vWF, factor XIII, and fibronectin.
    - Not considered as safe as the virus-inactivated plasma concentrates listed above and should not be used unless those are unavailable
  - Antifibrinolytics
    - Useful for mucosal bleeding
    - Contraindicated in patients with hematuria due to risk of retention of large blood clots in the renal collecting system
    - Given as adjunct to DDAVP
    - Aminocaproic acid may be given at 50 to 70 mg/kg (max: 5 g; lower doses may be effective) q4-6h IV or PO.
    - Tranexamic acid may be given at 10 to 15 mg/kg IV or 25 mg/kg (1,300 mg) PO q8-12h.

- Recombinant FVIIa/Novoseven
  - Used for patients who develop alloantibodies to vWF
  - Given as IV bolus of 90 &mgr;g/kg q2h or 20 &mgr;g/kg every hour until hemostasis is achieved

## *Second Line*

- Oral contraceptives raise vWF/FVIII levels and have a role in the treatment of chronic menorrhagia.
- Platelets may be given as an adjunct to factor concentrates if hemostasis has not been achieved.
- IVIG has been useful in some patients with AvWD associated with monoclonal gammopathy (9).
- Recombinant FVIIa has been used effectively in patients with type 3 vWD.

## *ISSUES FOR REFERRAL*

The diagnosis and management of vWD is not always straightforward; consider consultation with hematologist.

## *SURGERY/OTHER PROCEDURES*

Valve replacement or correction may be curative for patients with AvWD associated with underlying cardiovascular conditions.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- For patients with major bleeding or those undergoing major surgical procedures, levels of ristocetin cofactor/vWF activity and FVIII need to be restored to 80 to 100 IU/dL for first 2 days and then maintained >50 IU/dL for 5 to 7 days.
- For patients undergoing minor surgical procedures, maintain FVIII levels >50 IU/dL for 5 to 7 days.
- For patients delivering or in need of epidural anesthesia, obtain FVIII levels >50 IU/dL.

**ONGOING CARE**

## FOLLOW-UP RECOMMENDATIONS

Patients should be seen by a hematologist prior to invasive procedures for determination of perioperative management or advice regarding delivery.

### *Patient Monitoring*

Patients with mild disease do not require monitoring.

### *DIET*

No dietary restrictions are recommended. However, aspirin and other NSAIDs should be avoided due to their antiplatelet effects, which can exacerbate the bleeding phenotype.

## PATIENT EDUCATION

National Hemophilia Foundation: [www.hemophilia.org/NHFWeb/MainPgs/MainNHF.aspx?menuid=182&contentid=47&rptname=bleeding](http://www.hemophilia.org/NHFWeb/MainPgs/MainNHF.aspx?menuid=182&contentid=47&rptname=bleeding)

## PROGNOSIS

Most patients with vWD have a normal life expectancy.

## COMPLICATIONS

- Significant perioperative bleeding may occur.
- Patients with type 3 vWD and type 2N can have bleeding complications similar to patients with hemophilia A such as hemarthrosis and intracranial hemorrhage.
- Patients with aortic stenosis and AvWD are known to have higher rates of GI bleeding.
- Multiple transfusions may result in alloantibodies against vWF.
- Venous thromboembolism may result from supranormal levels of FVIII.

## Codes

**&NA;**

### ICD10

D68.0 Von Willebrand's disease

## Clinical Pearls

**&NA;**

- vWD varies from a minor to severe bleeding disorder; affects 1-2% of the U.S. population.
- It is important to determine the exact type of vWD (1, 2, or 3) to guide treatment.
- AvWD should be considered in patients with acquired bleeding disorder if they have underlying predisposing conditions.

# Vulvar Malignancy

Jay R. Patibandla, MD

Michael P. Hopkins, MD, MEd

## BASICS

### DESCRIPTION

- Premalignant lesions of the vulva are collectively known as vulvar intraepithelial neoplasia (VIN). Exposure to human papillomavirus (HPV) has been linked to >70% of VIN (1).
- Invasive squamous cell carcinoma is the most common malignancy involving the vulva (90% of patients); can be well, moderately, or poorly differentiated and derives from keratinized skin covering the vulva and perineum.
- Melanoma is the second most common type of vulvar malignancy (8%) and sarcoma is the third (1).
- Other invasive cell types include basal cell carcinoma, Paget disease, adenocarcinoma arising from Bartholin gland or apocrine sweat glands, adenoid cystic carcinoma, small cell carcinoma, verrucous carcinoma, and sarcomas.
- Sarcomas are usually leiomyosarcoma and probably arise at the insertion of the round ligament in the labium major; however, sarcoma can arise from any structure of the vulva, including blood vessels, skeletal muscle, and fat.
- Rarely, breast carcinoma has been reported in the vulva and is thought to arise from ectopic breast tissue.
- System(s) affected: reproductive

### Geriatric Considerations

- Older patients with associated medical problems are at high risk from radical surgery. The surgery, however, is usually well tolerated.
- Patients who are not surgical candidates can be treated with combination chemotherapy and/or radiation.
- In the very elderly, palliative vulvectomy provides relief of symptoms for ulcerating symptomatic advanced disease.

# EPIDEMIOLOGY

## Incidence

- In 2015, 5,150 women were diagnosed with vulvar cancer and 1,080 women died from vulvar cancer in the United States (2).
- Ethnic distribution: more common in Caucasian women than in any other race
- Surveillance, epidemiology, and end result (SEER) data showed that the incidence of in situ vulvar carcinoma increased by >400% between 1973 and 2000.
- Mean age at diagnosis 65 years; in situ disease: mean age 40 years; invasive malignancy: mean age 60 years (3)

## ETIOLOGY AND PATHOPHYSIOLOGY

- Patients with cervical cancer are more likely to develop vulvar cancer later in life, secondary to Òfield effectÓ phenomenon with a carcinogen involving the lower genital tract (3).
- HPV has been associated with squamous cell abnormalities of the cervix, vagina, and vulva; 55% of vulvar cancers are attributable to oncogenic HPV, predominantly HPV 16 and 33; 92% of VIN 2/3, vaginal intraepithelial neoplasia (VAIN) 2/3, and anal intraepithelial neoplasia (AIN) are attributable to HPV.
- Squamous cell carcinoma
  - The warty basaloid type, also known as bowenoid type, is related to HPV infection and occurs in younger women. Although traditionally graded in a three-level system, the International Society for the Study of Vulvovaginal Disease voted not to use a grading system for VIN in 2004. This system eliminated VIN 1 and combined VIN 2 and VIN 3. This is based on the fact that VIN 1 is not reproducible. VIN 2 and VIN 3 were combined because VIN 2 is rare and carries the same risk of progression to malignancy as VIN 3 (1).
  - The more common variant is simplex or differentiated and does not appear to be related to HPV, occurs in older age groups, and associated with lichen sclerosus and chronic venereal diseases; it is thought to carry a higher risk of progression to malignancy.
  - Melanoma, second most common histology, often identified in postmenopausal women; often pigmented but can be amelanotic, arising de novo, often found on clitoris or labia minora (1).
- Cases not associated with HPV infection are typically associated with vulvar dystrophies, such as lichen sclerosus or squamous cell hyperplasia.
- Smoking is associated with squamous cell disease of the vulva, possibly from direct irritation of the vulva by the transfer of tars and nicotine on the patient's hands or from systemic

absorption of carcinogen.

## *Genetics*

No known genetic pattern

## **RISK FACTORS**

- VIN or cervical intraepithelial neoplasia (CIN)
- Smoking
- Lichen sclerosus (vulvar dystrophy)
- HPV infection, condylomata or sexually transmitted diseases (STD) in the past
- Low economic status
- Autoimmune processes
- Immunodeficiency syndromes or immunosuppression
- Northern European ancestry

## **GENERAL PREVENTION**

- HPV vaccination has the potential to decrease vulvar cancer by 60% (3,4,5).
- Abstinence from smoking/smoking cessation counseling (1)

## **COMMONLY ASSOCIATED CONDITIONS**

- Patients with invasive vulvar cancer are often elderly and have associated medical conditions.
- High rate of other gynecologic malignancies

## **DIAGNOSIS**

### **HISTORY**

Complaints of pruritus or raised lesion in the vaginal area

### **PHYSICAL EXAM**

- In situ disease: a small raised area associated with pruritus, single vulvar plaque, ulcer, or mass on labia majora, perineum, clitoris
- Vulvar bleeding, dysuria, enlarged lymph nodes less common symptomatology

Invasive malignancy: an ulcerated, nonhealing area; as lesions become large, bleeding occurs with associated pain and foul-smelling discharge; enlarged inguinal lymph nodes indicative of advanced disease.

## ***DIFFERENTIAL DIAGNOSIS***

- Infectious processes can present as ulcerative lesions and include syphilis, lymphogranuloma venereum, and granuloma inguinale.
- Disorder of Bartholin gland, seborrheic keratosis, hidradenomas, lichen sclerosus, epidermal inclusion cysts
- Crohn disease can present as an ulcerative area on the vulva.
- Rarely, lesions can metastasize to the vulva.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Hypercalcemia can occur when metastatic disease is present.
- Squamous cell antigen can be elevated with invasive disease.

### ***Follow-Up Tests & Special Considerations***

- Upon examination, any suspicious lesions should be biopsied.
- Diagnosis based on histologic findings following vulvar biopsy (6)
- The vulva can be washed with 3% acetic acid to highlight areas and visualized with a colposcope, allows for visualization of acetowhite lesions and vascular lesions (6).
- For patients with new onset of pruritus, the area of pruritus should be biopsied.
- Liberal biopsies must be used to diagnose in situ disease prior to invasion and to diagnose early invasive disease.
- The patient should not be treated for presumed benign conditions of the vulva without full exam and biopsy, including Pap smear and colposcopy of cervix, vagina, and vulva.
- When symptoms persist, reexamine and rebiopsy.
- Treatment of benign condyloma of the vulva has not been shown to decrease the eventual incidence of in situ or invasive disease of the vulva.
- CT scan to evaluate pelvic and periaortic lymph node status if tumor >2 cm or if suspicion of metastatic disease (6)[A].

## Diagnostic Procedures/Other

Office vulvar biopsy is done to establish the diagnosis.

### Test Interpretation

A surgical staging system is used for vulvar cancer (International Federation of Obstetrics and Gynecology Classification).

- Stage I: tumor confined to the vulva
  - Stage IA: lesions  $\leq 2$  cm in size, confined to the vulva or perineum and with stromal invasion  $\leq 1$  mm, no node metastasis
  - Stage IB: lesions  $> 2$  cm in size or with stromal invasion  $> 1$  mm, confined to the vulva or perineum, with negative nodes
- Stage II: tumor of any size with extension to adjacent perineal structures (lower 1/3 urethra, lower 1/3 vagina, anus) with negative nodes
- Stage III: tumor of any size with or without extension to adjacent perineal structures (lower 1/3 urethra, lower 1/3 vagina, anus) with positive inguinofemoral lymph nodes
  - Stage IIIA
    - With 1 lymph node metastasis ( $\geq 5$  mm), or
    - 1 to 2 lymph node metastases ( $< 5$  mm)
  - Stage IIIB
    - With  $\geq 2$  lymph node metastases ( $\geq 5$  mm), or
    - $\geq 3$  lymph node metastases ( $< 5$  mm)
  - Stage IIIC: with positive nodes with extracapsular spread
- Stage IV: tumor invades other regional (upper 2/3 urethra, upper 2/3 vagina) or distant structures
  - Stage IVA: tumor invades any of the following:
    - Upper urethral and/or vaginal mucosa, bladder mucosa, rectal mucosa, or fixed to pelvic bone
    - Fixed or ulcerated inguinofemoral lymph nodes
  - Stage IVB: any distant metastasis, including pelvic lymph nodes (7)[B]

## TREATMENT

### *GENERAL MEASURES*

- Wide excision can be performed for carcinoma in situ, and any suspicious lesion should be excised for definitive diagnosis.
- Cystoscopy and sigmoidoscopy should be performed if there is a question of invasion into the urethra, bladder, or rectum.

### *MEDICATION*

- As an adjuvant therapy, fluorouracil (Efudex) cream for in situ disease can produce occasional results but is not well tolerated because of irritation of the vulva (8)[A].
- Chemoradiotherapy with cisplatin and 5-fluorouracil (5-FU) has been successful in advanced or recurrent disease, although local morbidity is increased (8)[A].
- Contraindications: elderly patients: If chemotherapeutic agents are used, pay close attention to the patient's performance status and ability to tolerate aggressive chemotherapy.

### *ISSUES FOR REFERRAL*

Patients may need care from a gynecologic oncologist and/or a radiation oncologist.

### *ADDITIONAL THERAPIES*

- Preoperative radiation therapy can be used in those with advanced vulvar cancer (6)[B].
- Adjuvant radiation should be considered with tumor size >4 cm, evidence of lymphovascular invasion, positive surgical margins, or lymph node involvement.
- Preoperative chemoradiation allows for a less radical surgical procedure in patients who are not surgical candidates (8)[A].
- Postoperative radiation decreases recurrence frequency and may improve survival (8)[A].
- Radiation is contraindicated with verrucous carcinoma because it induces anaplastic transformation and increases metastases.

### *SURGERY/OTHER PROCEDURES*

- In situ disease can be treated with wide excision or laser vaporization of the affected area. Laser vaporization is preferable in the younger patient, whereas wide excision is preferable in the elderly patient, in whom the risk of invasive disease is also higher (6)[A].

If tumor extension within <1 cm from structures that will not be removed, preoperative radiation to prevent inadequate surgical margins prior to excision

- Inguinofemoral lymphadenectomy removal of superficial inguinal and deep femoral lymph nodes
- 1 cm tumor-free margin is required because smaller margin would increase risk of recurrence (8)[A].
- Stage IA: radical local excision without lymph node dissection
- Stage IB: radical local excision with either sentinel lymph node biopsy (SLNB) or ipsilateral inguinofemoral lymph node dissection because the risk of metastases is >8%
- Stage II: modified radical vulvectomy and/or chemoradiation and groin node dissection
- Stages III and IV: neoadjuvant chemoradiation and less radical surgery
- Pelvic exenteration after radiation provides effective therapy for advanced or recurrent malignancies involving the bladder or rectum.
- More limited surgery
  - Has been undertaken for early invasive lesions, especially in young patients, to preserve the clitoris and sexual function
  - Sentinel lymph node biopsy (SLNB) also has been advocated for early invasive lesion (stage IB or higher). It has shown to accurately diagnose groin metastases in women with early vulvar cancer and unknown groin node status. This will limit the surgical morbidity associated with inguinofemoral lymphadenectomy (IFL) in those with early stage disease (9) [A].
  - Radical vulvectomy with bilateral groin node dissection through separate incisions provides better cosmetic results than en bloc technique.
  - Unilateral lymphadenectomy should be considered when lesion <2 cm, lateral lesion >2 cm from vulvar midline, or no palpable groin nodes (7)[B].

## ***INPATIENT CONSIDERATIONS***

Typically inpatient for treatment

### ***Admission Criteria/Initial Stabilization***

In advanced malignancy involving the urethra and rectum, concomitant cisplatin/5-FU chemotherapy with radiation produces a significant decrease in size of the primary tumor, usually obviating the need for pelvic exenteration.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Early stage, treated with surgery alone: clinical exam of the groin nodes and vulvar area every 6 months for 2 years; then annually
- Following chemoradiation, assessment for further treatment within 6 to 12 weeks of therapy completion
- Advance stage, clinical exam of the groin nodes and vulvar area every 3 months for 2 years; then every 6 months for 3 years, and then annually (10)[B]
- Cervical and/or vaginal cytology annually
- Majority of relapses occur within 1st year.

#### *DIET*

As tolerated and according to comorbid conditions

### *PATIENT EDUCATION*

- American College of Obstetricians and Gynecologists (ACOG), 409 12th St. SW, Washington, DC 20024-2188; (800) 762-ACOG; <http://www.acog.org/>
- American Cancer Society: <http://www.cancer.org/>

### *PROGNOSIS*

The 5-year survival is based on stage:

- Stage I: 78.5%
- Stage II: 58.8%
- Stage III: 43.2%
- Stage IV: 13.0%
- Inguinal and/or femoral node involvement is the most important determinant of survival (11) [A].

### **COMPLICATIONS**

- The major complications from radical vulvectomy and groin node dissection

are wound breakdown, lymphedema, urinary stress incontinence, and psychosexual consequences.

- Two common complications with radical vulvectomy and bilateral groin node dissection
  - In the immediate postoperative period, ~50% of patients experience breakdown of the wound. This requires aggressive wound care by visiting nurses as often as twice a day. The wounds usually granulate and heal over a period of 6 to 10 weeks.
  - ~15-20% of patients experience some form of mild to moderate lymphedema after the groin node dissection. These patients should be instructed in the use of leg elevation and support hose. <1% of patients experience severe, debilitating lymphedema.

## Codes

**&NA;**

### ICD10

- C51.9 Malignant neoplasm of vulva, unspecified
- D07.1 Carcinoma in situ of vulva
- C51.0 Malignant neoplasm of labium majus

## Clinical Pearls

**&NA;**

- 60% of vulvar cancers are attributable to oncogenic HPV, and 92% of all VIN 2/3, VAIN 2/3, and AIN are attributable to HPV. Therefore, HPV vaccination has the potential to decrease vulvar cancer by 1/3.
- Biopsy all suspicious or nonhealing vulvar lesions.

# Vulvodynia

Jessica Johnson, MD, MPH

Amy L. Wiser, MD

## BASICS

### DESCRIPTION

- Vulvar pain lasting 3 months or more. Occurs in the absence of relevant visible findings, relevant lab abnormalities, or a clinically identifiable neurologic disorder
- Classification by ISSVD is based on whether pain is generalized or localized and whether it is provoked (by physical contact), spontaneous, or mixed.
  - Generalized: involvement of majority of the vulva; usually persistent or spontaneous pain
  - Localized: severe pain of certain vulvar areas such as the vestibule (formerly known as *vestibulodynia*), usually provoked with touch or attempted vaginal entry; thought to be the leading cause of painful intercourse among premenopausal women
    - Primary: introital dyspareunia from first episode of intercourse or first insertion of tampon or vaginal speculum
    - Secondary: introital dyspareunia developing after a period of painless intercourse, tampon use, or speculum exams

### EPIDEMIOLOGY

- Most women diagnosed between age 20 and 80 years
- Nearly half of woman opt not to seek treatment (1).
- Patients are psychologically comparable with asymptomatic controls and have similar marital satisfaction.

### Incidence

- Recent retrospective study estimates annual rate of new onset vulvodynia to be 1.8% (2).
- Evidence indicates lifetime cumulative incidence approaches 15%, suggesting nearly 14 million U.S. women will experience persistent vulvar discomfort at some point in their lives (3).

## Prevalence

- Reports between 8.3% and 16%; non-clinical based studies approximate a prevalence of 7% with validation by exam (1).
- Studies show Hispanics are 80% more likely to present with vulvar pain compared with Caucasians and African Americans.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Vulvodynia is likely to be neuropathically mediated:
  - Allodynia and hyperalgesia are thought to result from neurogenic inflammation, leading to sensitization of primary afferents by inflammatory peptides, prostaglandins, and cytokines. Impulses transmitted to the CNS, where reinforcing signals sustain pain loop
  - In recent investigations of vulvar biopsy specimens, increased neuronal proliferation and branching in vulvar tissue are evident when compared with tissue of asymptomatic women.
- Pelvic floor pathology also should be considered: In one study, the vulvodynia group showed an increase in pelvic floor hypertonicity at the superficial muscle layer, less vaginal muscle strength with contraction, and decreased relaxation of pelvic floor muscles after contraction (3).
- No cause of vulvodynia has been established. It is most likely a neuropathic pain caused by a combination of the following:
  - Recurrent vulvovaginal candidiasis or other infections
  - Immune-mediated chronic neuro-inflammatory process within vulvar tissues
  - Chemical exposure (trichloroacetic acid) or physical trauma
  - Reduced estrogen receptor expression/changes in estrogen concentration
  - CNS etiology, similar to other regional pain syndromes

## RISK FACTORS

- Vulvovaginal infections, specifically candidiasis. Unclear if infection, treatment, or underlying hypersensitivity is the cause (1). Multiple infections compound this risk.
- Hormonal factors: Controversial evidence proposes increased risk with use of oral contraception pills (OCPs); early age at first use of OCPs and longer duration of use has been associated with increased risk.
- Pelvic floor dysfunction: Increased instability of pelvic floor muscles may perpetuate vulvar tissue inflammation, leading to vascular changes and histamine release.

- Comorbid interstitial cystitis and painful bladder syndrome; potentially related to common embryologic origin of structures
- Abuse: increased risk of vulvodynia if childhood had physical or sexual abuse by a primary family member; causal relationship remains unclear (3).
- Depression and anxiety (1)
- Other neuropathic disorders, including regional pain syndrome

## *Genetics*

Proposed genetic deficiency impairing one's ability to stop the inflammatory response triggered by infection or chemicals; homozygosity of the two alleles of the IL-1 receptor antagonist occurs in 25-50% of vestibulodynia patients, compared with <10% in controls (4).

## **GENERAL PREVENTION**

- Wear 100% cotton underwear in the daytime and no underwear to sleep.
- Avoid douching and other vulvar irritants such as perfumes, dyes, and detergents.
- Avoid abrasive activities and tight, synthetic clothing.
- Avoid panty liners.
- Clean the vulva with water only and pat area dry after bathing.
- Avoid use of hair dryers in the vulvar area.

## **COMMONLY ASSOCIATED CONDITIONS**

Higher incidence of chronic pain syndromes associated with vulvodynia, including chronic cystitis, irritable bowel syndrome, fibromyalgia, migraines, depression, endometriosis, low back pain.

Women with vulvodynia have a higher incidence of depression and anxiety both preceding and resulting from their symptoms (1).

## **DIAGNOSIS**

- Vulvodynia is a clinical diagnosis and it should be suspected in any women with chronic pain at the introitus and vulva (4)[B].
- Pain should be characterized using a standard measure such as the McGill Pain Questionnaire; duration and nature of the pain should be established. Use physical exam to rule out other causes of vulvovaginal pain. Negative fungal culture, along with relevant history and positive cotton swab test, confirm diagnosis.

## HISTORY

Adequate sexual, social, and pain history should be taken to assess degree of symptoms. Visual pain scales and pain diaries may be helpful (5)[B]:

- Onset of vulvodynia often sudden and without precedents
- Pain often described as generalized, unprovoked.
- Quality of pain is burning, stinging, irritating, or rawness (1).
- Specifically ask about bowel and bladder habits, history of trauma or abuse, history of infections including herpes, and personal hygiene.
- Specific skin complaints may suggest alternate diagnosis; a history of allergies may suggest vulvar dermatitis.
- Assess for precipitants of vulvar pain: tight garments, bicycle riding, tampon use, prolonged sitting, perfumed or deodorant soaps, douching (1)
- Assess for complaints of dyspareunia:
  - Presence of vaginismus (involuntary vaginal muscle spasm), adequate lubrication, anorgasmia, partner problems, abuse
  - Psychosexual morbidity significantly higher in patients with vulvodynia; counseling may complement medical interventions.

## PHYSICAL EXAM

- Ask patient to show where pain is localized or most painful.
- Mouth and skin exams to assess for lesions suggestive of lichen planus or lichen sclerosus
- Vaginal exam should be done to exclude other causes of vulvovaginal pain, including external inspection; palpation; and single digit, speculum, and bimanual exams:
  - The vulva may be erythematous, especially at the vestibule. Discomfort with separation of the labia minora is common.
  - Spontaneous or elicited pain at the lower 1/2 of anterior vaginal wall suggests bladder etiology.
- Bulbocavernosus and anal wink reflexes should be checked to assess for peripheral neuropathy.

## DIFFERENTIAL DIAGNOSIS

- Infections: candidiasis, herpes, human papillomavirus (HPV), bacterial vaginosis, trichomoniasis, dermatophytes
- Inflammation: lichen planus, immunobullous disorder, allergic vulvitis, lichen sclerosus,

atrophic vaginitis

- Neoplasia: Paget disease, vulvar or vaginal intraepithelial neoplasia, squamous cell carcinoma
- Neurologic/muscular: herpes neuralgia, spinal nerve compression, vaginismus

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Cotton swab or Q-tip test: Vulva tested for localized areas of pain beginning at thighs and continuing medially toward vestibule using the soft end and broken sharp end of the cotton swab. Five distinct positions (2,4,6,8, and 10 o'clock) surveyed using light palpation. Pain rated on a scale from 0 (none) to 10 (most severe). Posterior introitus and posterior hymenal remnants most common sites of increased sensitivity.
- Test for concurrent vaginismus: Apply pressure with a gloved finger to levator ani and obturator internus muscles to assess for tenderness, pain, or contracture.

### ***Initial Tests (lab, imaging)***

- Vaginal pH, wet mount, and yeast culture are recommended to rule out vaginitis.
- Gonorrhea and chlamydia testing done at physician's discretion
- HPV screening is unnecessary; no association has been identified between HPV and vulvodynia.

---

P.1135

### ***Follow-Up Tests & Special Considerations***

- Varicella-zoster and herpes simplex virus should be considered if ulcers or vesicular eruptions are present.
- Consider biopsy if concerned for neoplasm or dermatophyte infection or if the patient is resistant to treatment.

### ***Diagnostic Procedures/Other***

Colposcopy can be helpful if epidermal abnormalities are present. This should be done with caution because acetic acid worsens vulvar pain.

### ***Test Interpretation***

No specific histologic features are associated with vulvodynia, although reactive squamous atypia has been observed. Biopsies are unnecessary for diagnosis. Presence of rash/altered mucosa is not consistent with vulvodynia; this requires further evaluation (5)[C].

## TREATMENT

A trial of several medications for at least 3 months is usually needed.

### GENERAL MEASURES

Combining treatments should be encouraged when treating women with vulvodynia (5)[C]: Various reports on use of a combination of medical treatments, psychotherapy, and dietary intervention reveal women on these combinations do significantly better compared with those who receive medication only.

### MEDICATION

- Oral therapies
  - Tricyclic antidepressants (TCAs): first-line treatment for unprovoked vulvodynia (5)[B]; do not stop use abruptly; contraindicated in patients with cardiac abnormalities and those taking MAOIs; fatigue, constipation, sweating, palpitations, and weight gain are most common side effects
    - Amitriptyline, nortriptyline: most widely studied; start at 10 mg daily; dose should be titrated to pain control. Average effective dose is 60 mg daily. In one study, a 47% complete response rate was recorded (6)[B]. Nortriptyline may be preferred due to less anticholinergic adverse effects.
  - Anticonvulsant therapies:
    - Gabapentin: Started at 300 mg daily at HS and increased by 300 mg every 3 days. Maximum recommended dose is 3,600 mg daily divided into 3 doses. Dosing regimen limits popularity.
    - Topiramate and lamotrigine have been recommended if other therapies are not effective.
  - SSNRIs: not commonly used; however, have been helpful in those who cannot tolerate TCAs
    - Venlafaxine or duloxetine have also been used; evidence is limited.
  - Opioids/NSAIDs: not consistently helpful in relieving vulvar pain
- Topical therapies
  - A trial of local anesthetics may be recommended for all patients who present with vulvodynia. Use judiciously to avoid increased irritation (5)[C].
  - Lidocaine 5% ointment: for provoked vestibulodynia; application advised 15 to 20 minutes

prior to intercourse. Penile numbness and possible toxicity with ingestion can occur.

- In one study, lidocaine 5% ointment was left in vestibule overnight (average of 8 hours) for a period of 6 to 8 weeks; at follow-up, up to 76% of women reported no discomfort with intercourse (3)[C].
- Cromolyn 4% cream: decreases mast cell degranulation in vulvar tissue; recommended application TID (1)[C]
- Capsaicin 0.025%: decreases in discomfort and increases in frequency of intercourse with 20-minute daily application (3)[B]
- Topical amitriptyline 2% combined with baclofen 2% is helpful in patients with comorbid vaginismus.
- Topical corticosteroids and testosterone creams have not been shown to alleviate symptoms of vulvodynia.
- Gabapentin 3-6% ointment (must be compounded)
- Topical nitroglycerin may be helpful but may cause headaches.
- Topical estrogen
- Injectable therapies
  - Triamcinolone acetonide: no more than 40 mg should be injected monthly; is best when combined with 0.25-0.5% bupivacaine
  - Submucosal methylprednisone and lidocaine: reports of up to 68% response rate with weekly injections (5)[B]
  - Interferon- $\alpha$ : useful in treatment of vestibulodynia. Side effects (myalgias, fever, malaise) limit its use.
  - Botulinum toxin A injectable is being studied.

## ***ISSUES FOR REFERRAL***

A team approach is recommended for most effective management. Triage to psychosexual medicine, psychology, partner therapy, and pain management teams should be strongly considered (5)[B].

## ***ADDITIONAL THERAPIES***

- Cognitive-behavioral therapy (CBT): One randomized trial revealed that CBT is associated with a 30% decrease in vulvar discomfort with sexual intercourse. CBT is the recommended treatment for patients who present with dyspareunia as a main complaint (4)[B].

- Biofeedback/physical therapy: useful with concomitant vaginismus. Treats both generalized and localized vulvar pain; treatment value for unprovoked pain remains unclear. Most studies report an average of 12- to 16-week treatment time.
- Vaginal dilators
- Surface electromyography (sEMG): efficacious for pelvic floor rehabilitation. Patients are more likely to experience pain-free sexual intercourse after sEMG. Significant reductions seen on pain measures at long-term follow-up.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Acupuncture: Small studies of women with unprovoked vulvodynia who did not respond to conventional treatment reported significant decreases in pain severity with acupuncture; treatment value with provoked pain is unknown (5)[C].

## *SURGERY/OTHER PROCEDURES*

- Surgery may be considered for patients with localized symptoms who have failed to respond to other measures. Not recommended for generalized vulvodynia (5)[B]
- 60-80% of women who undergo surgery report a significant reduction in pain symptoms; however, when surveyed, patients prefer behavioral therapies than surgical intervention.
- All patients who are considering surgical intervention should be tested and treated for vaginismus. Vestibulectomy is less successful in this subgroup.
- Surgical approaches
  - Local excision: precise localization of painful areas; tissue closed in elliptical fashion
  - Total vestibulectomy: Tissue is removed from Skene ducts to perineum. The vagina is then brought down to cover defect.
  - Perineoplasty: vestibulectomy plus removal of perineal tissue; incision usually terminated above the anal orifice; reserved for severe cases (4)[B]

## **ONGOING CARE**

### *PATIENT EDUCATION*

Patients should be reassured that this condition is neither infectious, nor does it predispose to cancer (5)[C]. Emphasize self-hygiene. Encourage treatment with home remedies, including ice packs, sitz baths with baking soda, olive oil, and barrier cream to preserve moisture after bathing.

## PROGNOSIS

Traditionally viewed as a chronic pain disorder, new evidence of remission has been documented; recent 2-year follow-up study revealed 1 in 10 vulvodynia patients reported remission regardless of treatment (7).

## Codes

&NA;

## ICD10

- N94.819 Vulvodynia, unspecified
- N94.818 Other vulvodynia
- N94.810 Vulvar vestibulitis

# Clinical Pearls

**&NA;**

- Vulvodynia is a clinical diagnosis; it should be suspected in any woman with chronic pain at the introitus and vulva.
- A decrease in pain may take weeks to months and may not be complete.
- No single treatment is proven in all women; improvement over time is common even without treatment.

# Vulvovaginitis, Estrogen Deficient

Maria De La Luz Nieto, MD

## BASICS

### DESCRIPTION

- Vaginal atrophy is due to decreased blood flow to vaginal epithelium, resulting in thinning of the female genital tissues.
- Estrogen deficiency affects all tissues in the female body; however, the genital tissues are especially hormone-responsive and are most affected, leading to atrophy.
- Patients with estrogen-deficient vulvovaginitis may present with urinary incontinence, vaginal burning and itching, dyspareunia, increased urinary frequency, or recurrent UTIs.
- System(s) affected: reproductive

### EPIDEMIOLOGY

#### *Incidence*

- Predominant age: postmenopausal females. The average age of menopause in the United States is 51.3 years but ranges from 45 to 55 years old.
- May affect lactating women
- Predominant sex: female only
- May occur in younger women with premature ovarian failure

#### *Prevalence*

- Most postmenopausal women are affected to some degree.
- Up to 40% of postmenopausal women experience symptoms severe enough to seek treatment.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Decreased estrogen levels in the vagina and vulva result in decreased blood flow and decreased lubrication of vaginal and vulvar tissue.
- Vaginal and vulvar tissues become thin secondary to decreased vaginal cell maturation.

- Decreased cellular maturation results in decreased glycogen stores, which affects the normal vaginal flora and pH.
- Estrogen deficiency due to the following:
  - Menopause (surgical or natural)
  - Premature ovarian failure (chemotherapy, irradiation, autoimmune, anorexia, genetic)
  - Postpartum, lactation
  - Medications that alter hormonal concentration, such as gonadotropin-releasing hormone agonists, and antiestrogens, such as tamoxifen and danazol
  - Elevated prolactin from hypothalamic-pituitary disorders

## *Genetics*

No known pattern

## **RISK FACTORS**

Estrogen-deficient states

## **COMMONLY ASSOCIATED CONDITIONS**

- Urge and stress urinary incontinence
- Pelvic organ prolapse
- Frequent UTIs
- Bacterial vaginosis or yeast infections

## **DIAGNOSIS**

### **HISTORY**

- All female patients should be asked about symptoms because many women are embarrassed to discuss these issues with their health care providers (1) [C].
  - Vaginal dryness
  - Dyspareunia
  - Pruritus
  - Burning
  - Pressure

- Tenderness
- Malodorous discharge
- Urinary symptoms: dysuria, hematuria, frequency, infections, stress, and urge urinary incontinence
- Ask about self-treatment and products used.
- Determine exposure to irritants (e.g., soaps, feminine sprays, lotions, lubricants, constant pad use).

## ***PHYSICAL EXAM***

Evidence for the diagnosis includes the following:

- Loss of pubic hair
- Decreased vulvar and vaginal fullness
- Decreased vulvar subcuticular fat and moisture
- Pale-appearing, shiny, smooth vaginal and urethral epithelium
- Vaginal shortening, intolerance to speculum exams
- Loss of vaginal rugation
- Pelvic organ prolapse
- Shorten urethra

## ***DIFFERENTIAL DIAGNOSIS***

- Malignancy
- Dermatologic conditions of vulva and vagina:
  - Dermatitis
  - Lichen sclerosis
  - Lichen planus
- Bacterial or yeast vulvovaginitis

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Because vulvovaginitis is a clinical diagnosis, labs are not always necessary, but if suspect dermatologic or oncologic condition, biopsy is recommended (2)[A].

*Initial Tests (lab, imaging)*

However, the following labs may be obtained as corroborative of clinical impression:

- Check follicle-stimulating hormone (FSH) and estrogen levels. FSH rises and estrogen drops with menopause.
- Evaluate for infections via wet preparation and vaginal pH (usually >5).
- Urine dip and urinalysis if suspected concomitant UTI
- Perform cytology for maturation index: Higher proportion of parabasal cells and lower proportion of intermediate and superficial cells indicate decreased maturation index.

## *Follow-Up Tests & Special Considerations*

Drugs that may alter lab results:

- Estrogen therapy will alter the maturation index.
- Digoxin has estrogen-like properties.
- Tamoxifen may produce menopausal-type symptoms but also may act on genital tissues as a weak estrogen agonist.
- Progestins, danazol, and gonadotropin-releasing hormone agonists may produce a reversible pseudomenopause state.

## *Test Interpretation*

- Thinning of the cornified squamous layer of both the vulva and the vagina
- Increased parabasal cells
- Compact underlying collagenous tissue

---

P.1137

## **TREATMENT**

### *GENERAL MEASURES*

- Wear loose-fitting, undyed cotton underwear.
- Avoid prolonged pad use, especially scented pads.
- Avoid feminine deodorant sprays and douching.
- Use over-the-counter water-based lubricants, as needed.
- Symptomatic relief, if needed (e.g., cool baths or compresses)

## MEDICATION

- Vaginal estrogen can reverse atrophic changes and help to alleviate symptoms (3)[A].
  - Vaginal cream 1 g (conjugated equine estrogens or estradiol cream): Insert via applicator each night for 14 days and then 2 to 3 times per week.
  - Vaginal estradiol 10- $\mu$ g tablet: Insert via preloaded applicator each night for 14 days and then 2 to 3 times per week.
  - Estradiol-containing vaginal ring 2 mg: Insert into vagina, and replace every 3 months.
- Estrogen therapy should be used in the lowest possible dose for the shortest duration of time (4)[B].
- Long-term therapy may be necessary owing to the chronic nature of estrogen-deficient vulvovaginitis (5)[A].
- Systemic therapy typically is used as hormonal treatment of vasomotor symptoms and not for the primary treatment of estrogen-deficient vulvovaginitis.
- Contraindications
  - Breast or estrogen-dependent carcinoma
  - Undiagnosed vaginal bleeding
  - Thromboembolic disorders
  - Thrombophlebitis
  - Pregnancy
- Precautions: Any abnormal vaginal bleeding must be evaluated.
- Nonestrogen therapy: estrogen agonist/antagonist (6)[B]
  - Ospemifene (Osphena) 60-mg tablet daily
- Contraindications
  - Breast or estrogen-dependent carcinoma
  - Undiagnosed vaginal bleeding
  - Thromboembolic disorders
  - Thrombophlebitis
  - Hepatic impairment
- Precautions: Any abnormal vaginal bleeding must be evaluated, monitor for DVT and stroke.

## *ISSUES FOR REFERRAL*

- Refer to urogynecologist for evaluation if symptomatic due to pelvic organ prolapse and/or stress and urge urinary incontinence.
- Recurrent UTIs should be referred to urogynecology and/or urology for evaluation.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Outpatient treatment

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

No restrictions

### *Patient Monitoring*

Instruct the patient that symptoms should improve within 30 to 60 days. If they do not, reevaluate and reexamine for other causes.

### *DIET*

No special diet

## *PATIENT EDUCATION*

- American College of Obstetricians and Gynecologists (ACOG), 409 12th St., SW, Washington, DC 20024-2188; 800-762-ACOG; <http://www.acog.org/>
- Lactating postpartum women with high levels of prolactin are in a hypoestrogenic state. These women should be instructed to use lubrication for symptoms of dyspareunia and reassured that the symptoms will resolve when they are no longer breastfeeding.

## *PROGNOSIS*

The prognosis is excellent. Most symptoms will be alleviated with vaginal estrogen replacement therapy.

## **COMPLICATIONS**

- Recurrent UTIs may occur in women with vaginal atrophy.

Vaginal atrophy predisposes patients to vaginal infections.

## Codes

&NA;

## ICD10

- N95.2 Postmenopausal atrophic vaginitis
- E28.39 Other primary ovarian failure

## Clinical Pearls

&NA;

- Estrogen-deficient vulvovaginitis affects virtually all postmenopausal women to some degree.
- This disorder is often associated with urinary incontinence, increased urinary frequency, and

recurrent UTIs.

- Lab tests are generally unnecessary to make the diagnosis.
- Vaginal estrogen preparations, rather than systemic preparations, should be the first-line therapy in a woman whose primary complaint is associated with vaginal atrophy.

# Vulvovaginitis, Prepubescent

Sarah Parrott, DO

## BASICS

### DESCRIPTION

- Vulvitis is inflammation of the external genitals.
- Vaginitis, often associated with vaginal discharge, is inflammation involving the vaginal mucosa.
- In premenarchal girls, vulvitis is usually primary with secondary extension into the vagina.
- System(s) affected: reproductive, skin/exocrine
- Synonym(s): vaginitis; vulvitis

### EPIDEMIOLOGY

#### *Incidence*

Unknown

#### *Prevalence*

Most common gynecologic problem in prepubertal girls

### ETIOLOGY AND PATHOPHYSIOLOGY

- In the prepubertal child, the levels of estrogen are low.
- Due to the low levels of estrogen, the vaginal epithelium is thin, immature, and fragile.
- Absence of pubic hair and a well-developed labia as well as close proximity of the anus and vagina, make contamination more likely.
- The prepubertal child also has an absence of lactobacilli, creating a neutral to alkaline vaginal pH.
- Neutral pH, atrophic mucosa, and moist environment of the vagina increase the risk of infection.
- Most cases of pediatric vulvovaginitis are nonspecific inflammation.

- Specific infections that occur are typically respiratory, enteric, or sexually transmitted.
- Nonspecific vulvovaginitis
- Poor perineal hygiene
- Nonspecific chemical irritants (bubble baths, scented soaps, shampoos)
- Tight-fitting clothing
- Etiology
  - Bacterial: The most common bacteria are introduced from respiratory and GI tracts.
    - The most common respiratory pathogen is *Streptococcus pyogenes* (1)[B]. Vulvitis may occur in the absence of respiratory symptoms.
    - Urinary tract infections are common in children with vulvovaginitis (2)[B].
    - *Escherichia coli* is the most common fecal pathogen.
    - *Shigella* vaginitis is associated with mucopurulent bloody discharge and likewise, is not always accompanied by a history of diarrhea.
- *Enterobius vermicularis* (pinworms)
  - Very common in young children and certain populations
  - Should be considered in children with vaginal itching and irritation
  - Most common symptom is nocturnal perineal itching.
  - Foreign body
    - Presents with foul-smelling, bloody, or brown discharge from the vagina
    - Should be considered with recurrent vulvovaginitis where other causes have been eliminated
  - Other
    - With chronic vulvovaginitis, anatomic abnormalities or systemic disease should be considered:
      - Anatomic abnormalities include double vagina with fistula, ectopic ureter, and urethral prolapse.
  - Systemic disease (inflammatory diseases)
  - Other conditions, such as lichen sclerosus, vitiligo, psoriasis, and atopic dermatitis, should be considered.

## Genetics

Understudied

## RISK FACTORS

- Prepubertal girls are particularly susceptible due to behavioral and anatomic reasons:
  - Inadequate hand washing or perineal cleansing after urination and defecation
  - Tight-fitting clothing
  - Proximity of the vagina to the anus, lack of protective hair, and labial fat pads
  - Trauma
- Obese girls are also susceptible to nonspecific vulvovaginitis (3)[A].

## GENERAL PREVENTION

- Good perineal hygiene (including wiping from front to back)
- Urination with legs spread apart and labia separated
- Avoidance of tight-fitting clothing and nonabsorbent underwear
- Avoidance of irritants such as harsh/perfumed soaps and bubble baths

### ALERT

Cultures of sexually transmitted organisms in prepubertal children warrant investigations of sexual abuse.

## DIAGNOSIS

### HISTORY

- Irritation and erythema of vulva
- Itching
- Bleeding
- Vaginal discharge
- Unpleasant odor
- Dysuria
- Soreness

## *PHYSICAL EXAM*

- Look for evidence of chronic illness or dermatologic disease.
- Look for trauma or other signs that may correlate with abuse.
- Inspect the genital area in the supine position:
  - Excoriation of the genital area
  - Inflammation (erythema, swelling) of the introitus
  - Inspect the vagina and cervix in the knee-chest position or frog leg position.
  - Perform rectal exam if vaginal bleeding or abdominal pain.

## *DIFFERENTIAL DIAGNOSIS*

- Contact dermatitis
- Eczema
- Psoriasis
- Lichen sclerosus

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Culture for bacteria, fungi (yeast), or viruses (herpes)
- Urinalysis, urine culture, and urine for STI (via nucleic acid amplification test)
- Tape exam for pinworms
- Potassium hydroxide and saline smears of vaginal discharge, if present
- If an anatomic abnormality is suspected, imaging may be necessary to confirm.
- Consider consultation with a pediatric or adult gynecologist to determine the most appropriate imaging study.

### *Follow-Up Tests & Special Considerations*

Exploration of the vagina for a foreign body may be necessary in cases of persistent, recurrent vulvitis.

If blood or foul-smelling discharge is present, visualization is mandatory:

- Place the child in the knee-chest position for best results. Hold the buttocks apart and slightly upward.
- Visualization of the vagina may be necessary by using a nasal speculum or infant laryngoscope.
- If available, consider referral to a provider with specific training/experience in this specialized exam.

## TREATMENT

- The definitive diagnosis of bacterial vulvitis requires a culture of vulva and vaginal secretions.
- The typical colony count and bacterial mix are unknown in prepubescent girls. Antibiotic use should be directed against the species with the highest colony count.
- General hygiene should always be recommended, particularly in cases of a retained foreign body (e.g., toilet paper).
- When no cause is identified, treatment should focus on hygiene as well as minimizing soap exposure and tight-fitting clothes (1).

## GENERAL MEASURES

- Appropriate health care: outpatient (except where systemic illness requires hospital care)
- Soak the vulva/perineum in a small amount of clear, warm water for 15 minutes BID.
- If smegma is present in the labial folds, clean the area gently with a mild soap.

## MEDICATION

### *First Line*

- To break the itching-scratching-infection cycle, use a low-dose topical hydrocortisone cream for a limited time.
- Estrogen deficiency with labial adhesion/agglutination: estrogen cream 0.625 mg to fused area nightly for 2 weeks
- Emollients or protective creams may offer symptomatic relief.
- Antibiotic use should be restricted to cases of bacterial infection only (4)[A].
- Specific organisms on culture

- Group A *Streptococcus*, *S. pneumoniae*: penicillin V (Pen Vee K) 250 mg PO BID-TID for 10 days
  - *Haemophilus influenzae*: amoxicillin, 20 to 40 mg/kg/day PO divided TID for 7 days
  - *Staphylococcus aureus*: cephalexin, 25 to 50 mg/kg/day PO divided QID for 7 to 10 days or dicloxacillin, 25 mg/kg/day divided QID for 7 to 10 days or amoxicillin-clavulanate, 20 to 40 mg/kg/day PO divided BID for 7 to 10 days
  - *S. pyogenes*: amoxicillin, 50 mg/kg/day PO divided into 3 doses/day for 10 days
  - *Candida* sp.: topical nystatin (Mycostatin), miconazole, clotrimazole, or terconazole
  - *Shigella*: trimethoprim/sulfamethoxazole or ampicillin for 5 days
  - Pinworms: mebendazole, 100 mg PO, repeated in 2 weeks
  - *Chlamydia trachomatis*: <sup>2</sup>45 kg: erythromycin, 50 mg/kg/day QID for 14 days; <sup>3</sup>45 kg and <8 years old: azithromycin, 1 g PO single dose; <sup>3</sup>45 kg and <sup>3</sup>8 years old: azithromycin, 1 g PO single dose or doxycycline 100 mg BID for 7 days
  - *Neisseria gonorrhoeae*: <sup>2</sup>45 kg: ceftriaxone, 125 mg IM plus medication for chlamydia; >45 kg: ceftriaxone, 250 mg IM × 1 plus medication for chlamydia
  - *Trichomonas*: metronidazole, 15 mg/kg/day PO divided TID (max 250 mg TID) for 7 days
- Contraindications: allergy to proposed treatment
  - Precautions: Avoid potential allergens and topical sensitizers if possible.

## ISSUES FOR REFERRAL

- Suspected sexual abuse
- Suspected anatomic abnormality (except minor labial agglutination)
- Persistent, severe, or recurrent infections

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### Patient Monitoring

Monitor for fever, pruritus, and vaginal discharge.

#### DIET

- Healthy balanced diet, high in fiber to prevent constipation

- Adequate fluid intake

## PATIENT EDUCATION

### Hygiene

- Wipe front to back after elimination.
- Avoid bubble baths and other irritating products.
- Clean daily with mild soap and water and dry gently with soft towel or cool hair dryer.
- Apply bland ointments for skin protection, if necessary.

## PROGNOSIS

Excellent

### COMPLICATIONS

- If an STI is identified and not treated effectively, the patient is at risk for pelvic inflammatory disease (PID).
- Vaginismus

## Codes

**&NA;**

### ICD10

- N76.0 Acute vaginitis
- N77.1 Vaginitis, vulvitis and vulvovaginitis in dis classd elswhr

## Clinical Pearls

**&NA;**

- Vulvovaginitis is the most common gynecologic problem in prepubescent girls.
- The hypoestrogenic state and prepubescent anatomy may increase susceptibility to vulvar and vaginal infection.
- Treatment is typically supportive (avoid scratching, warm soaks) but may require antibiotics if a bacterial infection is suspected.
- Isolating an infection with known sexual transmission should prompt further investigation.
- Recurrent or persistent vulvitis, especially with foulsmelling discharge, should prompt a skilled exam of the vagina for a retained foreign body.
- Good perineal hygiene will limit this condition.

# Warts

Mercedes E. Gonzalez, MD, FAAD

Herbert P. Goodheart, MD

## BASICS

- Warts (verrucae) are benign growths that are confined to the epidermis. All warts are caused by the human papillomavirus (HPV). Warts can appear on any area of the skin or mucous membranes. Common warts are predominantly seen in children and young adults.
- Clinically, warts are rather arbitrarily described as the following:
  - Common warts (verrucae vulgaris)
  - Plantar warts (verrucae plantaris)
  - Flat warts (verrucae plana)
  - Venereal warts (condyloma acuminatum)
  - Epidermodysplasia verruciformis is a rare, lifelong hereditary disorder characterized by chronic infection with HPV.
- System(s) affected: skin/exocrine

## DESCRIPTION

- Common warts are most often found at sites subject to frequent trauma, such as the hands and feet. Because warts often vary widely in shape, size, and appearance, the various descriptive names for them generally reflect their clinical appearance, location, or both.
- For example, filiform (fingerlike) warts are threadlike, planar warts are flat, and plantar warts are located on the plantar surfaces (soles) of the feet.
- Genital warts, or condyloma acuminata, may be large and cauliflower-like, or they may consist of small papules.
- Warts on mucous membranes (mucosal papillomas), such as those in the mouth or vagina, tend to be white in color due to moisture retention.

## EPIDEMIOLOGY

## **Incidence**

- Predominant age: young adults and children
- Predominant sex: female = male

## *Prevalence*

- ÷ 7-10% of the U.S. population
- Common warts appear 2 times as frequently in whites as in blacks or Asians.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- HPV is a double-stranded, circular, supercoiled DNA virus.
- The virus infects epidermal keratinocytes, stimulating cell proliferation.
- Various strains of DNA HPV: To date, >150 different subtypes have been identified.
- Common warts: HPV types 2 and 4 (most common), followed by types 1, 3, 27, 29, and 57
- Palmoplantar warts: HPV type 1 (most common), followed by types 2, 3, 4, 27, 29, and 57
- Flat warts: HPV types 3, 10, and 28
- Butcher warts: HPV type 7
- The virus is passed primarily through skin-to-skin contact or from the recently shed virus kept intact in a moist, warm environment.

## **RISK FACTORS**

- HIV/AIDS and other immunosuppressive diseases (e.g., lymphomas)
- Immunosuppressive drugs that decrease cell-mediated immunity (e.g., prednisone, cyclosporine, and chemotherapeutic agents)
- Pregnancy
- Handling raw meat, fish, or other types of animal matter in one's occupation (e.g., butchers)
- Previous wart infection

## **GENERAL PREVENTION**

There is no known way to prevent warts.

**DIAGNOSIS**

- Most often made on clinical appearance
- Skin biopsy, if necessary

## *PHYSICAL EXAM*

- Distribution of warts is generally asymmetric, and lesions are often clustered or may appear in a linear configuration due to scratching (autoinoculation).
- Common wart: rough-surfaced, hyperkeratotic, papillomatous, raised, skin-colored to tan papules, 5 to 10 mm in diameter; several may coalesce into a larger cluster (mosaic wart); most frequently seen on hands, knees, and elbows; usually asymptomatic but may cause cosmetic disfigurement or tenderness
- Filiform warts: These are long, slender, delicate, fingerlike growths, usually seen on the face around the lips, eyelids, or nares.
- Plantar warts often have a rough surface and appear on the plantar surface of the feet in children and young adults.
  - Can be tender and painful; extensive involvement on the sole of the foot may impair ambulation, particularly when present on a weight-bearing surface.
  - Most often seen on the metatarsal area, heels, and toes in an asymmetric distribution (pressure points)
  - Pathognomonic "black dots" (thrombosed dermal capillaries); punctate bleeding becomes more evident after paring with a no. 15 blade.
  - Both common and plantar warts generally demonstrate the following clinical findings:
    - A loss of normal skin markings (dermatoglyphics) such as finger, foot, and hand prints
    - Lesions may be solitary or multiple, or they may appear in clusters (mosaic warts).
- Flat warts: slightly elevated, flat-topped, skin-colored or tan papules, small (1 to 3 mm) in diameter
  - Commonly found on the face, arms, dorsa of hands, shins (women)
  - Sometimes exhibit a linear configuration caused by autoinoculation
  - In men, shaving spreads flat warts.
  - In women, they often occur on the shins, where leg shaving spreads lesions.
- Epidermodysplasia verruciformis (rare): Widespread flat, reddish brown pigmented papules and plaques that present in childhood with lifelong persistence on the trunk, hands, upper and lower extremities, and face are characteristics.

## ***DIFFERENTIAL DIAGNOSIS***

- Molluscum contagiosum
- Seborrheic keratosis
- Epidermal nevus
- Acrochordon (skin tag)
- Solar keratosis and cutaneous horn
- Acquired digital fibrokeratoma
- Squamous cell carcinoma (SCC)
- Keratoacanthoma
- Subungual SCC can easily be misdiagnosed as a subungual wart or onychomycosis.
- Corns/calluses
  - Corns (clavi) are sometimes difficult to distinguish from plantar warts. Like calluses, corns are thickened areas of the skin and most commonly develop at sites subjected to repeated friction and pressure, such as the tops and the tips of toes and along the sides of the feet.
    - Corns are usually hard and circular, with a polished or central translucent core, like the kernel of corn from which they take their name.
    - Corns do not have black dots, and skin markings are retained except for the area of the central core.

### **ALERT**

- A melanoma on the plantar surface of the foot can mimic a plantar wart.
- Verrucous carcinoma, a slow-growing, locally invasive, well-differentiated SCC, also may be easily mistaken for a common or plantar wart.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### Diagnosis

- HPV cannot be cultured and lab testing is rarely necessary.
- Definitive HPV diagnosis can be achieved by the following:
  - Electron microscopy
  - Viral DNA identification employing Southern blot hybridization is used to identify the specific HPV type present in tissue.

- Polymerase chain reaction may be used to amplify viral DNA for testing.

## Follow-Up Tests & Special Considerations

Skin biopsy if unusual presentation or if diagnosis is unclear

### *Test Interpretation*

- Histopathologic features of common warts include digitated epidermal hyperplasia, acanthosis, papillomatosis, compact orthokeratosis, hypergranulosis, dilated tortuous capillaries within the dermal papillae, and vertical tiers of parakeratotic cells with entrapped red blood cells above the tips of the digitations.
- In the granular layer, HPV-infected cells may have coarse keratohyaline granules and vacuoles surrounding wrinkled-appearing nuclei. These koilocytic (vacuolated) cells are pathognomonic for warts.

## TREATMENT

- The abundance of therapeutic modalities described below is a reflection of the fact that none of them is uniformly or even clearly effective in trials. Placebo treatment response rate is significant and quality of evidence in general is poor. Beyond topical salicylates, there is no clear evidence-based rationale for choosing one method over another (1)[A].
  - The choice of method of treatment depends on the following:
    - Age of the patient
    - Cosmetic and psychological considerations
    - Relief of symptoms
- 
- Patient's pain threshold
  - Type of wart
  - Location of the wart
  - Experience of the physician

P.1141

## GENERAL MEASURES

- There is no ideal treatment.
- In children, most warts tend to regress spontaneously.

- In many adults and immunocompromised patients, warts are often difficult to eradicate.
- Painful, aggressive therapy should be avoided unless there is a need to eliminate the wart(s).
- For surgical procedures, especially in anxious children, pretreat with anesthetic cream such as EMLA (emulsion of lidocaine and prilocaine).

## *MEDICATION*

### **First Line**

- Self-administered topical therapy
  - Keratolytic (peeling) agents: The affected area(s) should be hydrated first by soaking in warm water for 5 minutes before application. Most over-the-counter agents contain salicylic acid and/or lactic acid; agents such as Duofilm, Occlusal-HP, Trans-Ver-Sal, and Mediplast.
- Office-based
  - Cantharidin 0.7%, an extract of the blister beetle that causes epidermal necrosis and blistering
  - Combination cantharidin 1%, salicylic acid 30%, and podophyllin resin 5% in flexible collodion; applied in a thin coat, occluded 4 to 6 hours, then washed off.

### *Second Line*

#### Home-based

- Imiquimod 5% (Aldara) cream, a local inducer of interferon, is applied at home by the patient. It is approved for external genital and perianal warts and is used off-label and may be applied to warts under duct tape occlusion. It is applied at bedtime and washed off after 6 to 10 hours. Applied to flat warts without occlusion.
- Topical retinoids (e.g., tretinoin 0.025-0.1% cream or gel) for flat warts

#### Office-based

- Immunotherapy: induction of delayed type hypersensitivity with the following:
  - Diphenylcyclopropanone (DCP) (2)[B]
  - Dinitrochlorobenzene (DNCP)
  - Squaric acid dibutylester (SADBE): There is possible mutagenicity and side effects with this agent.
- Intralesional injections

- Mumps or *Candida* antigen
- Bleomycin: Intradermal injection is expensive and usually causes severe pain.
- Interferon- $\alpha$ -2b
- Oral therapy
  - Oral high-dose cimetidine: possibly works better in children
  - Acitretin (an oral retinoid)
- Other treatments (all have all been used with varying results)
  - Dichloroacetic acid, trichloroacetic acid, podophyllin, formic acid, aminolevulinic acid in combination with blue light, 5-fluorouracil, silver nitrate, formaldehyde, levamisole, topical cidofovir (3)[B] or IV cidofovir for recalcitrant warts in the setting of HIV, and glutaraldehyde
- The quadrivalent HPV vaccine has cleared recalcitrant, chronic oral, and cutaneous warts (4) [C].

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Duct tape: Cover wart with waterproof tape (e.g., duct tape). Leave the tape on for 6 days, and then soak, pare with emery board, and leave uncovered overnight; then reapply tape cyclically for eight cycles; 85% resolved compared with 60% efficacy with cryotherapy (5)[A].
- Hyperthermia: safe and inexpensive approach; immerse affected area into 45°C water bath for 30 minutes 3 times per week
- Hypnotherapy
- Raw garlic cloves have demonstrated some antiviral activity.
- Vaccines are currently in development.

## Pregnancy Considerations

The use of some topical chemical approaches may be contraindicated during pregnancy or in women who are likely to become pregnant during the treatment period.

## SURGERY/OTHER PROCEDURES

- Cryotherapy with liquid nitrogen (LN<sub>2</sub>) may be applied with a cotton swab or with a cryotherapy gun (Cryogun). Aggressive cryotherapy may be more effective than salicylic acid (6)[A], but it is associated with increased adverse effects (blistering and scarring):
  - Best for warts on hands; also during pregnancy and breastfeeding

- Fast; can treat many lesions per visit
- Painful; not tolerated well by young children
- Freezing periungual warts may result in nail deformation.
- In darkly pigmented skin, treatment can result in hypo- or hyperpigmentation.
- Light electrocautery with or without curettage
  - Best for warts on the knees, elbows, and dorsa of hands
  - Also good for filiform warts
  - Tolerable in most adults
  - Requires local anesthesia
  - May cause scarring
- Photodynamic therapy: Topical 5-aminolevulinic acid is applied to warts followed by photoactivation (7)[B].
- CO<sub>2</sub> or pulse-dye laser ablation: expensive and requires local anesthesia
- For filiform warts: Dip hemostat into LN<sub>2</sub> for

10 seconds, then gently grasp the wart for

10 seconds and repeat. Wart sheds in 7 to 10 days.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### **Patient Monitoring**

1/3 of the warts of epidermodysplasia may become malignant.

#### **PROGNOSIS**

- More often than not (especially in children), warts tend to ÒcureÓ themselves over time.
- In many adults and immunocompromised patients, warts often prove difficult to eradicate.
- Rarely, certain types of lesions may transform into carcinomas.

#### **COMPLICATIONS**

- Autoinoculation (pseudo-Koebner reaction)

- Scar formation
- Chronic pain after plantar wart removal or scar formation
- Nail deformity after injury to nail matrix

# Codes

**&NA;**

## ICD10

- B07.9 Viral wart, unspecified
- B07.0 Plantar wart
- A63.0 Anogenital (venereal) warts

## Clinical Pearls

**&NA;**

- No single therapy for warts is uniformly effective or superior; thus, treatment involves a certain amount of trial and error.
- Because most warts in children tend to regress spontaneously within 2 years, benign neglect is often a prudent option.
- Conservative, nonscarring, least painful, least expensive treatments are preferred.
- Freezing and other destructive treatment modalities do not kill the virus but merely destroy the cells that harbor HPV.

# Wilms Tumor

John K. Uffman, MD, MPH

## BASICS

### DESCRIPTION

- An embryonal renal neoplasm containing blastemal, stromal, or epithelial cell types, usually affecting children <5 years of age
- Most common renal tumor in children; fifth most common pediatric malignancy
- Staging: In the United States, National Wilms Tumor Study Group (NWTSG) staging is done pretreatment based on radiographic imaging and surgery, whereas in Europe/Asia, Soci t  Internationale d'Oncologie P diatrique (SIOP) staging is done *after* neoadjuvant chemotherapy is administered (1):
  - I: tumor limited to kidney; completely excised
  - II: tumor extends beyond kidney; completely excised
  - III: residual nonhematogenous tumor confined to abdomen (lymph nodes positive, spillage of tumor, peritoneal implants, extension beyond resection region)
  - IV: hematogenous metastases
  - V: bilateral renal involvement
- System(s) affected: renal/urologic
- Synonym(s): nephroblastoma

### Pediatric Considerations

- Occurs only in children
- Most common renal malignancy in childhood

### EPIDEMIOLOGY

#### Incidence

- Frequency rare in East Asian populations than Whites

- Frequency higher in black children than in whites
- Predominant age: median age of 36.5 months
- Predominant sex: female > male (1.1:1)
- Represents 6-7% of all childhood cancers
  - > 80% are diagnosed before 5 years of age (median age is 3.5 years at diagnosis).
  - Wilms tumor makes up 95% of all renal cancers in children <sup>2</sup> 15 years (2).

## *Prevalence*

United States: 0.69/100,000; 7.6 cases/1 million children < 15 years old

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Hereditary or sporadic forms of genetic mutation
- Familial form: autosomal dominant trait with incomplete penetrance (1%)
- Potential of parental occupational exposure (machinists, welders, motor vehicle mechanics, auto body repairmen)

## *Genetics*

- Several congenital anomalies are known to be associated with Wilms tumor. A 2-stage mutational model has been proposed: occurrence in either hereditary form or sporadic form. Patients with aniridia have a deletion of the short arm of chromosome 11 (11p13).
- Abnormalities of chromosome 11 at the 11p15 locus are associated with Beckwith-Wiedemann syndrome. Wilms tumor-suppressor gene (*WT1*) has been identified as well as additional candidates for another suppressor gene (*WT2*). Chromosome band 17q12-17q21 has been linked to two kindreds with Wilms tumor, and other kindred are associated with a Wilms tumor predisposition gene at 19q13.3-19q13.4. Loss of heterozygosity at chromosomes 16q and 1p is associated with adverse outcome (1).
- p53 is associated with anaplastic Wilms tumors (2).

## *RISK FACTORS*

- Familial occurrence (5%) (2)
  - These patients tend to have earlier age of onset.
  - Familial patients have greater risk of bilateral disease.
- Parental occupation (machinists, welders, motor vehicle mechanics, auto body repairmen)

- Maternal exposure to pesticides prior to child's birth (3)
- High birth weight or preterm birth (3)
- Compared with firstborn, being a second or later birth may be associated with significantly decreased risk of Wilms tumor (3).

## GENERAL PREVENTION

- Routine surveillance in patients with syndromes associated with Wilms tumor
- Routine screening with serial renal US at 3- to 4-month intervals has been recommended in children who have syndromes associated with an incidence of Wilms tumor >5% (4)[C].
- Routine screening with serial renal US is also recommended for infants born to kindreds with familial Wilms (every 3 to 4 months until age 7 years) (4)[C].

## COMMONLY ASSOCIATED CONDITIONS

- Aniridia (partial or complete absence of iris) 600 times normal risk
- Hemihypertrophy (100 times normal risk)
- Cryptorchidism
- Hypospadias
- Duplicated renal collecting systems
- Denys-Drash syndrome (nephropathy, renal failure, male pseudohermaphroditism, Wilms tumor)
- Klippel-Trenaunay syndrome
- Wilms tumor, aniridia, genitourinary malformations, and mental retardation (WAGR) complex
- Beckwith-Wiedemann syndrome (visceromegaly, macroglossia, omphalocele, hyperinsulinemic hypoglycemia)

## DIAGNOSIS

- Symptoms of pain, anorexia, vomiting, malaise in 30% (1)
- >90% present with asymptomatic abdominal mass (5)

## HISTORY

- History of increasing abdominal size
- Usually asymptomatic; may have fever, abdominal pain

---

## *PHYSICAL EXAM*

- Palpable upper abdominal mass
- Fever, hepatosplenomegaly
- Rarely, signs of acute abdomen with free intraperitoneal rupture
- Cardiac murmur
- Ascites, prominent abdominal wall veins, varicocele
- Gonadal metastases
- Aniridia (present in 1.1% of Wilms tumor patients)
- Hypertension (20-65%) (1)

## *DIFFERENTIAL DIAGNOSIS*

- Neuroblastoma
- Hepatic tumor
- Sarcoma
- Rhabdoid tumor
- Cystic nephroma
- Renal cell carcinoma (generally occurs in older children)
- Mesoblastic nephroma: distinguished only by histology. Age usually <6 months, essentially benign, although metastases have been reported; tend to be locally invasive
- Nephroblastomatosis: considered premalignant; may present as nodularity of one or both kidneys

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Urinalysis (occasional hematuria, proteinuria)
- CBC (anemia)
- Lactate dehydrogenase
- Plasma renin (rarely helpful)
- Urine catecholamines
- Serum creatinine and calcium

- Coagulation factors
- Chest radiograph
- Abdominal US (with Doppler imaging): best initial test. Gives best information about tumor and extension into inferior vena cava
- CT scan (with IV and oral contrast material) of chest and abdomen. Allows anatomic visualization and excludes synchronous bilateral disease with a high degree of sensitivity (2)
- CT may have high sensitivity and specificity for atriocaval thrombus and obviate the needs for US (2).
- Chest lesions only identified on CT have improved event-free survival with three drug treatment regimens (6)[B].

### *Diagnostic Procedures/Other*

Occasionally, bone marrow aspiration is necessary to distinguish from neuroblastoma.

### *Test Interpretation*

- Favorable findings (mortality of 7%)
  - Bulky lesion, well encapsulated
  - Focal areas of hemorrhage and necrosis
  - Absence of anaplasia and sarcomatous cell types
  - Presence of blastemal, stromal, and epithelial elements (5)
    - Predominance of epithelial elements usually are less aggressive when diagnosed early but tend to be resistant to treatment when diagnosed late.
    - Predominance of blastemal elements indicate more aggressive tumors.
- Unfavorable histology (mortality rate of 57%)
  - Anaplasia: markedly enlarged and multipolar mitotic figures, 3-fold enlargement of nuclei in comparison with adjacent similar nuclei, hyperchromasia of enlarged nuclei; anaplasia may be diffuse or focal.
  - Sarcomatous changes: now considered to be separate from Wilms, not subtypes (mortality 64%)
  - Rhabdoid tumor of the kidney: now considered to be separate tumor from Wilms
- Nephroblastomatosis: considered premalignant
- Nephrogenic rests (5): These are precursor lesions found in 25-40% of Wilms; found in 1% of

infants at autopsy, but most do not develop into malignancy.

## TREATMENT

### GENERAL MEASURES

- Appropriate health care: inpatient workup and treatment until stable postoperatively and induction chemotherapy completed

P.1143

- Chemotherapy; some recommend pretreatment with neoadjuvant chemotherapy (1).
  - May decrease incidence of intraoperative tumor rupture (debatable)
  - May result in inappropriate treatment with chemotherapeutic agents of non-Wilms tumors (5%) or benign lesions (1.6%)
  - Results in the inability to directly compare treatment results worldwide
- Radiation therapy in stage II (unfavorable histology), stage III, and stage IV

### MEDICATION

#### First Line

- Children typically treated with protocols based on staging, histology, and other variables as part of a multimodal therapy approach (chemotherapy, radiation, surgery). The following medications may be used as part of a protocol:
- Dactinomycin (Actinomycin-D)
- Vincristine
- Doxorubicin
- Cyclophosphamide (Cytosan)
- Ifosfamide
- Etoposide
- Topotecan
- Irinotecan

#### Second Line

- Doxorubicin (Adriamycin)

- Cyclophosphamide

## ***SURGERY/OTHER PROCEDURES***

- Exploration of contralateral kidney no longer required if adequate CT done preoperatively
- Radical nephroureterectomy and lymph node sampling is needed to provide precise staging information.
- Renal-sparing resection
  - Tumors are usually too large, but 10-15% may be amenable to partial nephrectomy if given preoperative chemotherapy (4)[C].
  - May be recommended for patients with high risk of bilateral disease or renal failure (4)[C]
- Sampling of any enlarged lymph nodes (absence of any lymph nodes in the surgical specimen mandates treatment as stage III disease) (5)[B]
- Identification of any retained tumor with titanium clips
- Tumor should be given to pathologist fresh, not in formalin.
- Vertical midline incision if tumor extension to right atrium~increased morbidity (2)
- Bilateral Wilms tumors (represent 4-6% of Wilms) (5)[B]
  - Preoperative chemotherapy with reevaluation by CT or MRI after 6 weeks (some are biopsied prior to chemotherapy)
  - Renal-sparing operation at 6 weeks if good response to chemotherapy:
    - Partial nephrectomy or wedge excision of tumor is preferred but only if it does not compromise tumor resection.
    - Kidney with lowest tumor burden is addressed first. If successful resection is accomplished, radical nephrectomy can be done on the contralateral kidney. Bilateral partial nephrectomy may be possible in some cases.
- Preoperative treatment also generally is accepted in a solitary kidney, horseshoe kidneys, intravascular extension of tumor above the intrahepatic vena cava, and in the case of respiratory distress from extensive metastatic tumor.
- Treatment of patients with relapsed Wilms (7)[B]: Current treatment is either with chemotherapy with or without radiation therapy alone or high-dose chemotherapy followed by autologous stem cell rescue.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### **Patient Monitoring**

- Multidrug chemotherapy every 3 to 4 weeks for 16 weeks to 15 months depending on stage
- Every 4 months for 1 year, every 6 months for second to third year; yearly after that
- CBC, CT of chest and abdomen with each visit
- Patients at high risk for developing Wilms tumor should be monitored with renal US every 3 to 4 months until 5 years of age. Patients with Beckwith-Wiedemann syndrome or Simpson-Golabi-Behmel syndrome should have yearly US until 7 years of age (8)[C].

#### *PATIENT EDUCATION*

- Possibility of second malignancy (up to 12% by age 50 years)
- Side effects of chemotherapy, radiation therapy

#### *PROGNOSIS*

- With favorable histology (1)
  - Children <2 years of age and stage I, favorable histology: 98% survival in NWTSG 1 to 3 studies
  - Children with stage III, favorable histology tumor: overall survival of 89% in NWTSG 3 to 4 studies
- With diffuse anaplasia (1)
  - Children with stage I, diffuse or focal anaplasia: overall survival 82.6%
  - Stage II tumors with anaplasia: overall survival 81.5%
  - Stage III tumors with anaplasia: overall survival 66.7%
  - Stage IV tumors with anaplasia: overall survival 33.3%
- With bilateral involvement (stage V): 4-year survival 81.7% (1)
- With rhabdoid features: 19% 3-year survival
- Survival of patients with relapsed Wilms tumor is 40-70% (8)[B]:
  - Patients with pulmonary relapse only had higher 4-year survival rate (77.7%) compared to

other sites (41.6%).

## COMPLICATIONS

- Complication rate of 6-10%
- 1-2% will develop second malignant neoplasms (leukemia, lymphoma, hepatocellular carcinoma, soft tissue sarcoma): 12.2% by 50 years of age
- High risk of delivering low-birth-weight infants, perinatal mortality in offspring of female survivors of Wilms tumor
- Chest is usual site of recurrence.
- Occurrence of second malignant neoplasms in 2% of patients 7 to 34 years after treatment
  - Bone and soft tissue sarcomas, breast cancer, hepatocellular carcinoma, lymphoma, gastrointestinal tract tumors, melanoma, leukemias
- Surgical complications
  - Postoperative small bowel obstruction (5-7%)
  - Tumor rupture with spillage in 15.3% according to NWTSG-5; this may be spontaneous or surgical and results in upstaging the tumor. Only 2.7% of spills are considered avoidable. Incidence of tumor spillage is reported at 2.2% by SIOP following preoperative neoadjuvant chemotherapy (5)[B].
- Local tumor recurrence
  - Abdominal tumor recurrence after tumor spillage is reduced by radiation therapy (10 or 20 Gy).
- Renal failure
- Cardiomyopathy (usually related to doxorubicin and radiation therapy)
- Impaired pulmonary function (radiation therapy)

## Codes

**&NA;**

### ICD10

- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- C64.1 Malignant neoplasm of right kidney, except renal pelvis
- C64.2 Malignant neoplasm of left kidney, except renal pelvis

## Clinical Pearls

**&NA;**

- Wilms is the most common renal tumor in children; it is an embryonal renal neoplasm containing blastemal, stromal, or epithelial cell types, usually affecting children <5 years of age.
- Nephrectomy performed as soon as possible after completing radiographic evaluation is the major component in tumor staging.

- Sampling regional lymph nodes or specifically mentioning "No nodes present" in the operative report is necessary or the tumor will automatically be considered stage III.

# Zollinger-Ellison Syndrome

Douglas S. Parks, MD

## BASICS

### DESCRIPTION

- Zollinger-Ellison syndrome (ZES) triad
  - Markedly elevated gastric acid secretion
  - Peptic ulcer disease
  - A gastrinoma or non-*β*g<sub>r</sub>; islet cell tumor of the pancreas or duodenal wall that produces gastrin
    - Gastrinomas (at the time of diagnosis) may be single or multiple (1/2 to 2/3), large or small, benign or malignant (2/3), sporadic (70-75%) or associated with *multiple endocrine neoplasia type 1* (MEN1) (25-30%).
- System(s) affected: endocrine/metabolic, gastrointestinal
- Synonym(s): Z-E syndrome; pancreatic ulcerogenic tumor syndrome; multiple endocrine neoplasia, partial; ulcerogenic islet cell tumor

### EPIDEMIOLOGY

#### *Incidence*

- 1 to 3 per million per year in the United States
- Predominant age: middle age (30 to 65 years). Mean age of onset is 43 years. Presents a decade earlier in patients with ZES/MEN1.
- Predominant sex: male > female (1.3:1)

#### *Pediatric Considerations*

Aggressive cases have been reported in teenagers.

#### *Pregnancy Considerations*

Rare, pregnancy alters medication choices and surgical timing.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Gastrinoma is equally distributed between the head of the pancreas and the first or second portion of the duodenum; if in the pancreas, the lesion is more likely to metastasize to the liver.
- Hypergastrinemia results in gastric mucosal hypertrophy and increased acid production. Increased acid production causes mucosal ulceration. Diarrhea and malabsorption are also common in ZES.
- Also may be found rarely in the mesentery, peritoneum, spleen, skin, or mediastinum (possibly metastasis with primary not identified)

## Genetics

÷25-30% of cases occur in association with the MEN1 syndrome—tumors of pancreas, pituitary, and parathyroid.

## RISK FACTORS

- MEN1
- Family history of ulcer disease

## GENERAL PREVENTION

Screen first-degree relatives of patients with MEN1.

## COMMONLY ASSOCIATED CONDITIONS

- MEN1
- Insulinoma
- Carcinoid tumors

## DIAGNOSIS

### HISTORY

Average of 5 years of symptoms, including recurrent ulcers before diagnosis is made

- Abdominal pain is the most common symptom (80%).
- Diarrhea (postprandial and fasting) (70%)
- Heartburn (60%)

- Nausea (30%)
- Reflux esophagitis
- Vomiting that is unresponsive to standard therapy
- Weight loss

## *PHYSICAL EXAM*

- Hepatomegaly with metastasis
- Conjunctival pallor if anemic
- Jaundice (tumor compressing common bile duct)
- Epigastric tenderness
- Dental erosions
- Heme + stools on rectal exam
- Complications of severe peptic ulcer disease, including hemorrhage, perforation, and obstruction
- Signs of MEN1 are hypercalcemia, hyperparathyroidism, and Cushing syndrome.

## *Geriatric Considerations*

Consider the diagnosis in a patient with persistent or recurring peptic ulcer disease; it is a less aggressive disease if it appears after 65 years.

## *DIFFERENTIAL DIAGNOSIS*

- Elevated serum gastrin with hypochlorhydria/achlorhydria
  - Atrophic gastritis
  - Drug-induced (associated with proton pump inhibitors [PPIs])
  - Gastric cancer
  - Pernicious anemia
  - Postvagotomy
- Elevated serum gastrin with normal or increased gastric acid
  - Antral G-cell hyperfunction
  - Chronic renal failure
  - *Helicobacter pylori* infection

- Gastric outlet obstruction
- Retained gastric antrum
- Consider gastrinoma in all patients with the following symptoms:
  - Recurrent or refractory ulcer disease
  - Gastric hypertrophy and ulcers
  - Duodenal and jejunal ulcers
  - Ulcers and diarrhea
  - Ulcers and kidney stones
  - Hypercalcemia and ulcers
  - Pituitary disease
  - Family history of ulcer disease or endocrine tumors suggestive of MEN1

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Preferred test is secretion stimulation test: gastrin level >100 pg/mL (>100 ng/L) (1,2)[A].
- Some gastrin assays undermeasure serum gastrin. If have strong index of suspicion but gastrin levels low, may need to repeat with a different lab (3)[B].
- Gastric secretory studies: basal acid output
- Alternative test is calcium infusion test: gastrin level >400 pg/mL (test is less specific and more dangerous because of IV calcium infusion).
- Elevated serum gastrin fasting level: >1,000 pg/mL with ulcers diagnostic; >200 pg/mL with ulcers is suggestive.
- Elevated basal gastric acid output: >15 mEq/hr (>15 mmol/hr)
- Gastric pH <2 with elevated gastrin
- Check serum calcium, phosphorus, cortisol, and prolactin to rule out MEN1.
- Drugs may alter lab results:
  - Histamine (H<sub>2</sub>) blockers and PPIs may increase gastric pH and serum gastrin.
  - Hold PPIs 7 days and H<sub>2</sub> blockers 2 days prior to drawing gastrin level.
- Endoscopic US: finds 24-38% of primary tumors
- Endoscopic findings include esophagitis, duodenal ulceration with multiple ulcers, and

prominent gastric and duodenal folds.

- Used to localize tumor for possible resection
- Much more likely to find tumors >3 cm (95%) than <1 cm (<15%) (4)[B]
- Abdominal CT scan: most useful for pancreatic tumors and metastasis >3 cm
- Abdominal US, MRI, and angiography are not typically useful except in large tumors.
- Somatostatin receptor scintigraphy (SRS): more sensitive than radiologic studies, still only finds 30% of small tumors
- Portal venous sampling and selective venous sampling for gastrin can localize the area of tumor and metastasis (80-90% sensitivity).
- Brain imaging (MRI) and serum calcium are useful if MEN1 is suspected.
- Because pancreatic tumors are most likely to be large and to metastasize to the liver (worse prognosis), SRS and an abdominal CT scan are suggested to look for resectable tumors. Surgical resection may improve prognosis (5)[B].

### *Diagnostic Procedures/Other*

Endoscopy may reveal tumors in the duodenal wall; multiple ulcers, including jejunal ulcers; and prominent gastric and duodenal folds.

### *Test Interpretation*

- 90% of gastrinomas are found in the gastric triangle (the borders are the bile duct, the junction of second and third portions of the duodenum, and the junction of the head and body of pancreas).
- ÷50% of gastrinomas are in the head of the pancreas (more likely >3 cm, metastasis to liver).
- ÷50% of gastrinomas are in the wall of the first or second portion of duodenum (more likely to be small, solitary).
- 2/3 of gastrinomas are malignant.
- 50% of gastrinomas stain positive for adrenocorticotrophic hormone (ACTH), vasoactive intestinal polypeptide, insulin, or neurotensin.
- 1/3 of patients have metastasis on presentation: regional nodes > liver > bone, > peritoneum, spleen, skin, and mediastinum.
- Biopsy shows hyperplasia of antral gastrin-producing cells, and histology is similar in appearance to carcinoid.

## TREATMENT

### GENERAL MEASURES

- Goals are to control acid hypersecretion and resect the tumor.
- Advanced imaging initially to evaluate for resection
- Surgical removal when primary tumor can be identified and as adjunct to control symptoms
- Medical treatment for symptom control when primary tumor is not found or metastasis on initial diagnosis

### MEDICATION

- PPIs are the first-line treatment; add H<sub>2</sub> blockers.
- Medications heal 80-85% of ulcers, most of which recur. Lifelong medication use should be anticipated.
- 4- to 8-fold higher PPI dose often necessary
  - Start at a lower dose, and titrate to symptoms (or maximum recommended dosage).
- If hyperparathyroidism is present (MEN1), correct hypercalcemia.

### First Line

- PPIs
  - Omeprazole 60 to 120 mg/day
  - Lansoprazole 60 to 180 mg/day (doses >120 mg need to be divided BID)
  - Rabeprazole 60 to 100 mg/day up to 60 mg BID
  - Pantoprazole 40 to 240 mg/day PO; 80 to 120 mg q12h IV
- H<sub>2</sub> blockers
  - Cimetidine 300 mg q6h up to 2.4 g/day
  - Ranitidine 150 mg q12h up to 6 g/day
  - Famotidine 20 mg q6h; up to 640 mg/day
- Contraindications
  - Known hypersensitivity to the drug

- H<sub>2</sub> blockers: antiandrogen effects, drug interactions due to cytochrome P450 inhibition
- PPIs: none
- Precautions
  - Adjust doses for geriatric patients and patients with renal insufficiency.
  - Gynecomastia has been reported with high-dose cimetidine (>2.4 g/day).
  - PPIs may induce a profound and long-lasting effect on gastric acid secretion, thereby affecting the bioavailability of drugs depending on low gastric pH (e.g., ketoconazole, ampicillin, iron).
- Significant possible interactions: Consider drug-drug interactions and consult prescribing materials accordingly.

## *Second Line*

- Octreotide may slow growth of liver metastases, or (occasionally) promote regression. Octreotide LAR can be given every 28 days (4)[B].
- Chemotherapy regimens using streptozocin, 5-fluorouracil, and doxorubicin shows limited response.
- Interferon shows a limited response but may be useful in combination with octreotide.

## *SURGERY/OTHER PROCEDURES*

- Laparotomy may be necessary to search for resectable tumors unless patient has liver metastasis on presentation or MEN1; surgery improves outcomes (6)[B].
- Definitive therapy: removal of identifiable gastrinomas (95% of tumors are found at the time of surgery; 5-year cure is 40% when all are removed)
- Total gastrectomy is rarely indicated.
- In MEN1, parathyroidectomy, by lowering calcium, may also decrease acid production and decrease antisecretory drug use. Gastrinomas in MEN1 are generally small, benign, and multiple, and surgery is not usually curative in this situation.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Titrate medication to symptom control
- Appropriate surveillance postoperatively to look for metastasis

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Longitudinal follow-up to evaluate for metastases
- Titrate medical therapy to control symptoms.
- Advise patients of potential danger of stopping antisecretory treatment. Rare cases have been reported of severe adverse outcomes within 2 days of stopping PPIs (7)[B]. Gastric acid analysis can help guide medical therapy to maintain basal gastric acid output at <10 mEq/hr (<2 mEq/hr if patient has complications such as perforation or esophagitis).

#### *DIET*

Restrict foods that aggravate symptoms.

### *PATIENT EDUCATION*

Inform patients as to the nature of disease and prognosis.

### *PROGNOSIS*

- Overall survival rate: 5 to 10 years: 69-94%
- The prognosis improves with complete surgical removal of the tumor.
- If liver metastasis is present on initial surgery, 5-year survival is 30-40%; 10-year survival is 25%.
- Mortality is directly related to liver metastasis tumor size and presence of pancreatic tumors (4,5)[B].

### **COMPLICATIONS**

- Complications of peptic ulcer disease (bleeding, perforation, obstruction)
- 2/3 of gastrinomas are malignant with metastasis.
- Paraneoplastic phenomena (e.g., production of ACTH with resulting Cushing syndrome) is possible.
- Decrease in vitamin B<sub>12</sub> levels is possible with longterm PPI use (8)[A].

## Codes

**&NA;**

### ICD10

E16.4 Increased secretion of gastrin

## Clinical Pearls

**&NA;**

- Consider ZES if peptic ulcers recur or if high doses of PPI are needed to control symptoms/ulcers.
- ÷25-30% of cases of ZES occur in association with MEN1.
- Once ZES is diagnosed, it is important to search for gastrinomas in the head of the pancreas and the first or second portion of the duodenum.
- PPIs heal ZES ulcers. Patients should anticipate lifelong therapy.
